Pompions, there be of several kinds, some proper to the Country, they are dryer then our English Pompions, and better tasted; you may eat them green.

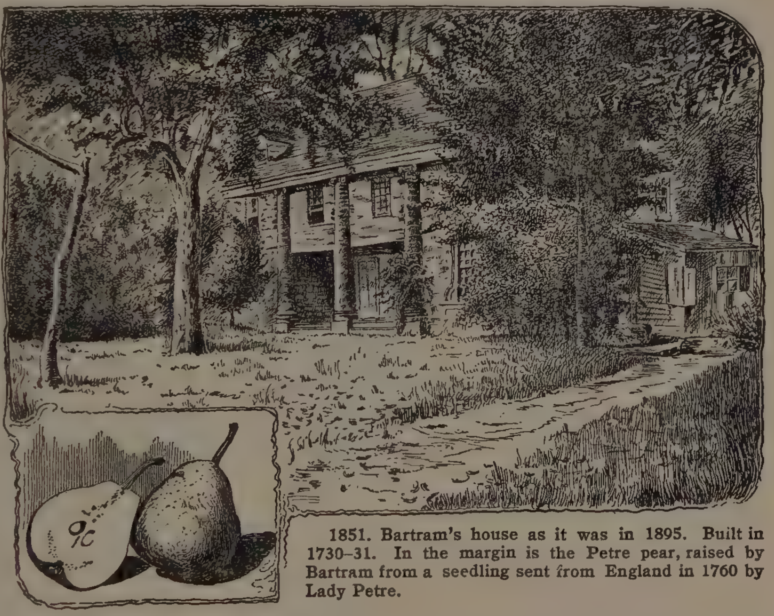
Tuckerman, who edited an edition of Josselyn in 1865, comments as follows on the foregoing lists: "The earliest, almost the only account that we have of the gardens of our fathers, after they had settled themselves in their *New* England, and had tamed its rugged coasts to obedience to English husbandry. What with their garden beans, and Indian beans, and pease ('as good as ever I eat in England,' says Higginson in 1629); their beets, parsnips, turnips, and carrots ('our turnips, parsnips, and carrots are both bigger and sweeter than is ordinary to be found in England,' says the same reverend writer); their cabbages and asparagus,—both thriving, we are told, exceedingly; their radishes and lettuce; their sorrel, parsley, chervil, and marigold, for pot-herbs; and their sage, thyme, savory of both kinds, clary, anise, fennel, coriander, spearmint, and pennyroyal, for sweet herbs,—not to mention the Indian pompions and melons and squanter-squashes, 'and other odde fruits of the country,'—the first-named of which had got to be so well approved among the settlers when Josselyn wrote in 1672, that, what he calls 'the ancient New England standing dish' (we may call it so now!) was made of them; and, finally, their pleasant, familiar flowers, lavender-cotton and hollyhocks and satin ('we call this herbe, in Norfolke, sattin,' says Gerard; 'and, among our women, it is called honestie') and gillyflowers, which meant pinks as well, and dear English roses, and eglantine,—yes, possibly, hedges of eglantine,—surely the gardens of New England fifty years after the settlement of the country, were as well stocked as they were a hundred and fifty years after. Nor were the first planters long behindhand in fruit. Even at his first visit, in 1639, our author was treated with 'half a score of very fair pippins,' from the Governor's Island in Boston Harbor; though there was then, he says, 'not one apple tree nor pear planted yet in no part of the country but upon that island.' But he has a much better account to give in 1671: 'The quinces, cherries, damsons, set the dames a work. Marmalad and preserved damsons is to be met with in every house. Our fruit trees prosper abundantly,—apple trees, pear trees, quince trees, cherry trees, plum trees, barberry trees. I have observed, with admiration, that the kernels sown, or the succors planted, produce as fair and good fruit, without grafting, as the tree from whence they were taken. The countrey is replenished with fair and large orchards. It was affirmed by one Mr. Woolcut (a magistrate in Connecticut Colony), at the Captain's messe (of which I was), aboard the ship I came home in, that he made five hundred hogsheads of syder out of his own orchard in one year.'—*Voyages*, pp. 189, 190. Our barberry-bushes, now so familiar inhabitants of the hedge-rows of eastern New England, should seem from this to have come, with the eglantines, from the gardens of the first settlers. Barberries 'are planted in most of our English gardens,' says Gerard."

The foregoing lists and comments show that the colonists early brought their familiar home plants to the new country; and there are many collateral evidences of the same character. There was long and arduous experimenting with plants and methods. Several things which were tried on a large scale failed so completely, either from uncongenial conditions or for economic reasons, that they are now unknown to us as commercial crops; amongst these are indigo, silk and the wine grape. The histories of these things can be traced only as a refrain in contemporary writing. Indian corn, tobacco and cotton early became the great staple crops.

The Indians cultivated corn, beans, pumpkins and other plants when America was discovered. They soon adopted some of the fruits which were introduced by the colonists. William Penn and others found peaches among the Indians. Orchards of peaches and apples were found in western New York by Sullivan's raid against the Six Nations in revolutionary times. Josselyn, Roger Williams, Wood and others speak of the corn and squashes of the Indians. The word squash is adopted from the Indian name, *squontersquash*, *askutasquash*, or *isqoutersquash*. C. C. Jones, in his "History of Georgia," in describing the explorations of De Soto, says that before reaching the Indian town of Canasagua (whose location was in Gordon County, Georgia), DeSoto "was met by twenty men from the village, each bearing a basket of mulberries. This fruit was here abundant and well flavored. Plum and walnut trees were growing luxuriantly throughout the country, attaining a size and beauty, without planting or pruning, which could not be surpassed in the irrigated and well-cultivated gardens of Spain." For critical notes on the plants cultivated by the American aborigines, see Gray and Trumbull, "American Journal of Science," Vol. XXV (April, May), Vol. XXVI (August). For an account of plant products used by the Indians, see G. K. Holmes, "Cyclopedia of American Agriculture," Vol. IV, p. 24.

"Fruit-growing among the Indians of Georgia and Alabama in the early history of these states," writes Berckmans, "is demonstrated by the large quantity of peaches which the Indian traders of the early colonial period found growing in the Creek, Cherokee and Choctaw villages. It is on record that Indians often made long trips to other tribes for exchanging various articles of their making, and thus the seed from those peach trees was undoubtedly procured from the Florida Indians, who, in turn, procured these from the trees planted by the Spanish explorers. The peculiar type of 'Indian peaches,' found throughout the South and recognized by the downy and striped fruit and purple bark on the young growth, was introduced from Spain and gradually disseminated by the Indians. Apple-growing was quite extensively carried on by the Cherokee Indians in the mountain regions of Georgia, Alabama and North Carolina. The trees being all seedlings, as grafting was likely unknown to the Red Man, vestiges of old apple trees originally planted by these denizens of the South are still occasionally found in upper Georgia. Sixty years ago a large collection of apples was introduced into cultivation, and today many of the best southern winter apples owe their origin to the Indians, who procured the first seeds from traders."

One of the earliest glimpses of plant-growing in the New World is an account in the "Philosophical Transactions of the Royal Society," early in the eighteenth century, by Chief Justice Paul Dudley, of Roxbury, near Boston. In the "Abridgement of the Transactions" are the following notes, amongst others, under the date 1724: "The plants of England, as well as those of the fields and orchards as of the garden, that have been brought over into New England, suit very well with the soil, and grow to perfection. The apples are as good as those of England, and look fairer, as well as the pears; but they have not all of the sorts. The peaches rather excel those of England, and there is no trouble or expence of walls for them; for the peach trees are all standards, and Mr. Dudley has had, in his own garden, 700 or 800 fine peaches of the rare-ripes, growing at a time on one tree. . . . The peach trees are large and fruitful, and commonly bear in three years from the stone. . . . The common cherries are not so good as the Kentish cherries of England; and they have no dukes, or heart-cherries, unless in two or three gardens." It was reported that people of "late years have run much upon orchards." The product of these orchards was chiefly cider. "Some of their apple trees will make six, some have made seven barrels of cider; but this is not common; and the apples will yield from seven to nine bushels for a barrel of cider: a good apple tree will measure from 6 to 10 feet in girt." Dudley mentions a bloomless apple, and "the tree was no graft." In common with other new countries, New England astonished persons with the luxuriant growth of the plants. "An onion, set out for seed, will rise to 4 feet 9 inches in height. A parsnip will reach to 8 feet; red orrice [orach will mount 9 feet; white orrice 8. In the pastures he measured seed mullen 9 feet 2 inches in height, and one of the common thistles above 8 feet." Record is made of a pumpkin vine which grew unattended in a pasture. It made a single stem which "ran along over several fences, and spread over a large piece of ground far and wide." "From this single vine were gathered 260 pumpkins; one with another as large as a half peck; enough in the whole, to fill a large tumbrel, besides a considerable number of small and unripe pumpkins." Indian corn was "the most prolific grain." The observations and experiences of John Lawson in North Carolina should not be overlooked. He was in the country 1700 to 1708, and wrote a history of the state, describing its natural productions. He found considerable success there in grape-growing.



1851. Bartram's house as it was in 1895. Built in 1730–31. In the margin is the Petre pear, raised by Bartram from a seedling sent from England in 1760 by Lady Petre.

The colonial ornamental gardens were probably unlike our own in the relative poverty of plants, absence of landscape arrangement, rarity of greenhouses, and lack of smooth-shaven lawns (for the lawnmower was not invented till last century). These gardens were of two general types: the unconventional personal garden, without form but not void, in which things grew in delightful democracy; the conventional, box-bordered, geometrical garden, in which things grew in most respectful aristocracy. There were many interesting and elaborate private gardens in the colonial days. One of the earliest and best was that of Governor Peter Stuyvesant, of New Amsterdam (New York, near Third Avenue), known as the "Bouwerie," where forty or fifty negro slaves, and also white servants, were kept at work. "The road to the city has been put in good condition, and shade trees were planted on each side where it crossed the Governor's property." The Bowery of these degenerate days has lost the Eden-like features that distinguished its illustrious progenitor.

Excellent gardens were attached to the residences of wealthy persons by the middle of the eighteenth century, and probably earlier, and they were said to have been encouraged by the example and precept of Washington. There are records of many meritorious collections of plants a century and more ago. William Hamilton's collection at Philadelphia was one of the best, and it contained a large collection of exotics. It flourished toward the close of the eighteenth century, and was broken up in 1828. William Jackson began "a highly interesting collection of plants at his residence in Londongrove," Pennsylvania, in 1777. About 1800 Joshua and Samuel Pierce, East Marlborough, Pennsylvania," began to adorn their premises by tasteful culture and planting," and by the establishment of an arboretum of evergreens. The most famous botanic garden which North America has had was John Bartram's, established at Philadelphia in 1728 (p. 530). It contained a great collection of native plants, and some of the trees are now amongst the most valued landmarks of the city. Bartram was a skilful farmer and gardener, and his sons, John and William, inherited his tastes and continued the garden. The elder Bartram was probably the first American to perform successful experiments in hybridization. Bartram's house (Fig. 1851), built by himself, is still one of the sights of the environs of Philadelphia, and the site of the garden, with many of the old trees standing, is now happily a public park. Bartram's cousin, Humphry Marshall, established a botanic garden at West Bradford, in Chester County, Pennsylvania, in 1773 (p. 348). John Bartram's name is preserved in the moss Bartramia, and Marshall's in the genus Marshallia, applied to small Compositæ of the eastern states. The Elgin botanic garden, near New York, was established in 1801 by David Hosack, a man of great learning and of the keenest sympathies with rural occupations. He is now remembered in the interesting genus Hosackia, one of the Leguminosæ. A botanic garden was established at Charleston, South Carolina, about 1804, and one in Maryland about the same time. The Botanic Garden at Cambridge, Mass., was begun in 1805, an institution which, together with the Professorship of Natural History at Cambridge, was founded largely through the efforts of the Massachusetts Society for Promoting Agriculture. The society subscribed $500 for the purpose, and raised more by subscription.

Development of horticulture in Canada in particular.

(W. T. Macoun.)

Horticulture in Canada is about 300 years old. Its development began with the French who settled in Acadia (now the province of Nova Scotia), and along the banks of the St. Lawrence River, and planted seeds and trees brought with them from France. Owing to the small population and the difficulty in transportation, it was not until about sixty years ago that commercial horticulture may be said to have begun (say about 1850), but with the rapid increase of population and transportation facilities the development in recent years has been rapid. The growth of the fruit industry in the province of Ontario may be given as an example of how rapidly horticulture is developing in Canada. In 1859 the Ontario Fruit-Growers' Association was formed. In 1881 the first coöperative shipments of fruit were made, but coöperation was slow in developing for some years after. Spraying with paris green for the control of codlin-moth was practised in 1889 and shortly afterward spraying with bordeaux mixture for the control of apple-scab was begun. In 1895 the Department of Agriculture began to give demonstrations in spraying. Now spraying is very general throughout Canada. In 1894, fruit experiment stations, mainly for testing varieties of fruits, were established in different parts of Ontario by the provincial government. By 1904, the coöperative movement was developing rapidly, by 1908 there were thirty-five coöperative organizations in the province, and in 1914 there were fifty-seven. In 1904, the first provincial fruit and flower show was held in the city of Toronto and there has been one annually ever since, its importance increasing every year. The agricultural college at Guelph, through its horticultural courses, has been of great assistance in the development of this industry. The district representatives who carry demonstration work and diffuse information throughout the counties have been of great service in the different provinces. In other provinces, especially in the provinces of Nova Scotia and British Columbia, there has also been great development in fruit-culture in recent years.

The Dominion government has done much to aid horticulture in Canada. The Experimental Farms were established in 1887, on an Act passed in 1886, and now there are eighteen scattered from the Atlantic to the Pacific (page 1195). The Fruit Marks' Act (now the Inspection and Sales Act), passed in 1901, has materially helped the fruit industry in establishing definite grades of apples and requiring more careful packing than in former years. Other Acts passed by the Dominion government in recent years have been a great aid. In recent years, fruit crop-reports have been published monthly, part of the year, which have been of great assistance to the fruit-growers.

The canning of fruit is developing rapidly in Canada and the outlook for still more extensive growth in this branch of the industry is very bright.

The census of Canada for 1911 gives the total number of fruit trees in Canada as 20,812,556; the area occupied by fruit trees as 376,322 acres and the estimated capital value of fruit trees as $127,000,000.

As Canadians have become better off, there has been a growing demand for flowers and vegetables out of season and there has been a fairly rapid increase in the area under glass. It is estimated that there are now over 6,000,000 square feet devoted to floriculture, with an estimated capital invested of $1,500,000, and an annual output of $1,800,000; but this will soon be much larger.

The growing of vegetables began with the first settlement of Canada, and as the villages, towns and cities multiplied, the vegetable-growers supplied their needs. Now there are large areas devoted to the commercial culture of vegetables. In the province of Ontario many vegetables are canned and large quantities of corn and tomatoes particularly are grown for this purpose. In recent years the vegetable-growers have organized and in Ontario there is a provincial association.

For further information, see *British North America*, Vol. I, pp. 559–76.

Early horticulture in California in particular.

(Charles Howard Shinn.)

California horticulture is in the main patterned after the south-European types, and to this extent it originated from Spanish-Mexican sources. The horticulture of California's high mountain valleys approximates more closely to that of colder regions, while the horticulture of the Pacific slope, north of California, becomes more and more different from the south-European types, but still has many characteristics of its own separating it sharply from that of the Atlantic slope. The first horticultural experiments in California were at the Missions of the Peninsula (Bajo or Lower California), where twenty-two Missions were founded between 1697 and 1797 (Fig. 1852). Here the Mission Fathers introduced the date palm; also oranges, lemons, limes, pineapples, bananas, olives, figs, pomegranates, peaches, quinces, plums, apples, pears and grapes. They shipped to Monterey and the northern missions large quantities of dried figs, grapes, dates, and peaches. The Upper California missions received seeds, cions, and so on, from those of Lower California, as well as from Mexico. The first of these missions was established in 1769 at San Diego by the Franciscans, under the leadership of Father Junipero Serra, whose name visitors to the California State Building at the World's Fair will recall in connection with the great date palm from the Mission Valley of San Diego. This palm was raised from seed which Junipero Serra planted about 1770. Twenty-one missions were founded by the Franciscans, the last one in 1823, and at all but one or two of them there were important collections of the fruits of southern Europe—olives, figs, oranges, lemons, pomegranates, wine grapes, and also apples, pears and peaches. Early in this century the Mission of San Gabriel had over 2,000 fruit trees, and others had more than a thousand. Fig. 1852 shows the yard of San Juan Capistrano Mission, as it existed in 1889. There are also some traces in California of the fruits of the few early Russian settlements. With the American occupation and the immigration from the east, came the eastern American types of fruits, and the state is now the seat of a wonderfully varied fruit-culture, although the small-fruits have not yet attained that prominence which they enjoy in older countries.

1852. One of the early California missions, where were the early promoters of horticulture on the western coast.—San Juan Capistrano.

The first official horticultural reports from California appeared in the second part of the United States Patent Office Report for 1851. In this report, A. Williams, of San Francisco, presented statistics from the Horner Ranch, near the Mission San Jose, Alameda County, where 800 acres were planted in vegetables and the crop of 1851 sold for upwards of $200,000. The crop of potatoes, onions, beets, turnips and tomatoes was 134,200 bushels. The same report noted an onion weighing twenty-one pounds, and at the Fair of 1853 the committee on vegetables reported a "white flat turnip" weighing thirty-three pounds, a squash that weighed one hundred and twenty-one pounds, and a tomato weighing five and one-half pounds. Thus early California began to boast of the mammoth productions of her soil. The first official report printed in California appeared in a document issued by the secretary of state for 1852. The capital then employed in "fruits and orchards" was given at $366,910. The market-garden interests were surprisingly large; among single items were "460,000 pumpkins, worth $46,000;" upward of 5,000,000 pounds of onions, "worth $186,000;" 30,000 bushels of beans, "worth $72,000." Santa Barbara County reported "1,370 barrels of olives, worth $27,500." Horticultural statistics are continued in the reports of the state surveyor general. In December, 1853, the State Agricultural Society of California was organized, after a successful exhibition in San Francisco, where almonds, figs, olives, walnuts, and many other fruits, as well as vegetables and flowers, were shown.

Fairs were held in 1854 and 1855, but were not officially reported. The state began to publish the proceedings of the agricultural society in 1858, when its membership was 856, and annual reports have continued till the present time. The California Horticultural Society was organized April 5, 1881; in 1883, the State Board of Horticulture was established. Reports of these bodies and of the state fruit-growers' conventions have appeared annually or biennially since 1882. The State Viticultural Commission was organized in 1881, and its reports continued until 1894. Upward of one hundred octavo volumes represent the official output of California since 1858 in lines of horticulture, including, of course, the California Experiment Station reports.

Among the special California horticultural literature that appeared prior to 1900, are the following: "California Fruits," E. J. Wickson, first edition, 1889; second edition, 1891; third edition, 1900. So many changes and additions have occurred in this book that all three editions will be found very useful in libraries. "California Vegetables," E. J. Wickson, 1897. "Gardening in California," Wm. S. Lyon, Los Angeles, 1897. This is a small volume of 156 pages. "Olive Growing," Pohndorff, San Francisco, 1884. "Olive Culture," A. Flamant, San Francisco, 1887. "The Olive," Arthur T. Marvin, San Francisco, 1888. "The Raisin Industry," Gustav Eisen, San Francisco, 1890. "The Wine Press and Cellar," E. H. Rixford, San Francisco, 1883. "Grape Culture, a Handbook for California," T. Hart Hyatt, San Francisco, 1876. "Orange Culture in California," Thomas A. Garey, San Francisco, 1882. Contains appendix on grape-culture, by L. J. Rose. "Orange Culture," W. A. Spalding, Los Angeles. "The California Farmer," established in January, 1854, and maintaining a spasmodic existence for a number of years, printed the first pomological and horticultural reports of committees, and the like. "The Pacific Rural Press" was established in 1871, in San Francisco, and still continues. "The Rural Californian," of Los Angeles, still in existence, was established in 1877. "The California Fruit-Grower," began in 1888, and survives as the "California Fruit News." "The California Cultivator," of Los Angeles, established in 1884, is still published. "The Pacific Tree and Vine," of San José, established in 1884, is no longer published.

Sometimes we are inclined to think that the literature of the garden began on the Pacific coast in the age of steam presses, telegraphs and transcontinental railroads. It is not so; and we should go farther back than the excellent writings listed above. The "first fine rapture" of discovery and conquest gave birth to a splendid enthusiasm for the flowers and plants of the vast unfenced wilderness stretching from Texas to Oregon, and one finds its expression in hundreds of books of travel, in ponderous government reports, in forgotten periodicals and, to some extent in the whole outdoor literature of Europe and America during the exciting period of the gold rush to California.

We once had many and very quaint publications in California, all dead and forgotten now, but still worth studying in the libraries. There was the old "Alta California," the "California Farmer," the "Golden Era," the "Hesperian," the "Pioneer," "Hutching's Pioneer Magazine." They contained stilted essays, sketches and stories, often modeled after forgotten literary patterns of New York and Paris. But their descriptive writings first broke away from these hampering traditions, and shaped themselves anew under California skies. Ewer, "Shirley," Hutchings, Wadsworth, Dr. Kellogg and a few others wrote of things as they saw them, and in some degree caught the outdoor charm of the new land as it was slowly yielding to spade and plow.

But there had been a still earlier discovery of the floral wealth of the Pacific coast. Long before Marshall's mill-race gleamed with that fateful flake of gold, the botanists and collectors had sent forth a cry of delight that stirred the pulses of Europe. The letters, journals and various contributions to descriptive and scientific literature, made by the long line of botanical explorers who visited this coast between 1790 and 1848, should be a part of this record. Among these enthusiasts were men like Langsdorf, who accompanied that unfortunate Count Rozanoff of Bret Harte's beautiful poem, and Chamiso and Eschscholtz. The last two, friends close-linked in literature and science, gave our orange-hued poppy its consonantal name.

The starting-point, however, for most students of the floral resources of California is with the extensive work done by David Douglas (1825–1833), under the auspices of the Royal Horticultural Society of England. In the proceedings of that Society one finds some of his reports and the first colored plates ever issued of many California bulbs. The second volume of Hooker's "Companion to the Botanical Magazine" contains his fascinating letters. After Douglas came Coulter, Nuttall, Hartweg and others, and then the famous groups of botanical explorers whose work appears in government publications, such as the Pacific Railroad and Boundary Survey reports. Men like Gray, Thurber, Newberry, Torrey, Engelmann and Parry wrote much that was a real gift to the literature of the period, and in many cases they had for illustrations those wonderful pen-and-ink drawings made by T. C. Hilgard.

But, if one says that government reports are only the "raw material" of outdoor literature, then turn to Edinburgh, in 1859–1860, when Dr. Andrew Murray published his two parts of "Notes on California Trees," compiled chiefly from the letters of his brother Wm. Murray of San Francisco, and illustrated with superb lithographs of the sequoias. It was in 1860, also, that Thomas Starr King wrote a very charming account of a trip "Around the Bay in the season of flowers," when, as he expressed it, there were "flowers by the acre, flowers by the square mile."

Here we begin to reach the modern way of looking at things. All through the pages of the publications of the State Agricultural Society between 1856 and 1860, the early reports of the State Surveyor General, the "State Register" for 1857–60, the rambling surveys of Dr. Trask, the first state geologist, we have had somewhat obscure glimpses of a land overflowing with growth and blossom. We have seen the pioneer surveyors, Day and Goddard and the rest, camping in the lily-beds of the high Sierra valleys; we have watched pioneer committees going around, away back in the early fifties, to tell us, all too briefly, of the glories of Shell Mound Nurseries, the New England Gardens, Hook Farm, Fontainbleau, and other places now, alas! in ruins. We hear of Fox, Sontag, Prevost, Macondray, Lewelling. These reports, though hardly the literature of the garden, are very excellent materials out of which, some of these days, the right man or woman will reconstruct the whole story, and give us our long-needed book on "California Floriculture."

The "modern note" in our garden literature, aside from the glowing essays of Thomas King, was also manifest in some of the California writings of Dr. Bushnell. Then it found fuller expression in the pages of the "Overland Monthly," where Muir, the LeContes, Avery, Williams, Miss Coolbirth, Bartlett and Sill, and a little later, some of Professor Sill's pupils, made for a few years a very striking presentation of the life, color, strength and beauty of outdoor California. Much of the best writing of this period between 1868 and 1875 appeared in the "Bulletin," "Argonaut," "California Horticulturist" and "Rural Press." It is notable historically, because it covers the whole field. Nothing that is now being written about gardens and flowers is in its way any better than some of the work, signed and unsigned, that appeared in the "Overland Monthly," and in other San Francisco publications in the days before the gaudy splendors of the sensational Sunday newspapers.

In the way of distinctive floral publications we have had two of importance: The first, the "California Horticulturist," founded by F. A. Miller in 1870, lasted ten years. One of its most interesting editors was the late E. J. Hooper, one of the owners of the "Western Farmer and Gardener," established by him in Cincinnati in 1839 and 1840. Plates of fruit and flowers, colored by his hands, appear in early volumes of the "California Horticulturist." The still earlier and yet more rare "California Culturist" of W. Wadsworth, which began with June, 1858, and continued two years, contained a good deal of floriculture.

In May, 1888, at Santa Barbara, appeared the "California Florist," an attractive publication which soon moved to San Francisco and there continued until May, 1889. Since that date, outside of trade publications, catalogues, and occasional pamphlets, the floral interests of California have been, most of the time, without a separate publication, but they have never lacked for space, whenever required, in other periodicals.

There have been few books in the past twenty-five years which deal other than casually with the floral field, but there have been many and excellent botanies, chiefly local, and more are being written, so that before long the whole field will be covered, and brought down to date with revised nomenclature and description. In these brief limits, one cannot expect even a partial bibliography, of either the popular or the technical writings of California botany or floriculture. Beginning with the writings of Kellogg, Bolander, Lemmon, Miller, Ludeman, Sievers, Wickson, Rixford, and others, the list ends with the many bright people who write for the press on these topics at the present time. The standard early work on California plants is Brewer and Watson's "Botany of California," comprising two volumes of the State Geological Survey, published 1876–1880. Books like Bartlett's "Breeze from the Woods," and Mary Elizabeth Parson's "Wild Flowers of California," and such pamphlets as Lyon's "Gardening in California" and Krause's "Sweet Pea Review" have a real historial value. Prominent among our notable books are Kellogg's "Forest Trees," his "West American Oaks," and Green's "Flora Franciscana." Later is Jepson's "Flora of Western Middle California," 1901, with a second edition in 1911. He is now preparing a "Flora of California," several parts of which have been issued.

Native species of fruits and vegetables.

Before passing to a discussion of the departments or subdivisions of the subject, we may pause to consider the general contribution that the North American continent has made to the species of food-plants of a horticultural character. The remarks are taken from Hedrick (presidential address, Society of Horticultural Science, 1913), who has presented an excellent running summary: "The continent is a natural orchard. More than 200 species of tree, bush, vine and small fruits were commonly used by the aborigines for food, not counting nuts, those occasionally used, and numerous rarities. In its plums, grapes, raspberries, blackberries, dewberries, cranberries and gooseberries North America has already given the world a great variety of new fruits. There are now under cultivation 11 American species of plums, of which there are 433 pure-bred and 155 hybrid varieties; 15 species of American grapes with 404 pure and 790 hybrid varieties; 4 species of raspberries with 280 varieties; 6 species of blackberries with 86 varieties; 5 species of dewberries with 23 varieties; 2 species of cranberries with 60 varieties and 2 gooseberries with 35 varieties. Here are 45 species of American fruits with 2,226 varieties, domesticated within approximately a half-century.

"Few plants grow under such varied conditions as our wild grapes. Not all have been brought under subjugation, though nearly all have horticultural possibilities. It is certain that some grape can be grown in every agricultural region of the United States. The blueberry and huckleberry, finest of fruits, and now the most valuable American wild fruits, the crops bringing several millions of dollars annually, are not yet domesticated. Coville has demonstrated that the blueberry can be cultivated. [See *Blueberry*, Vol. I, p. 515.] Some time we should have numerous varieties of the several blueberries and huckleberries to enrich pine plains, mountain tracts, swamps and waste lands that otherwise are all but worthless. A score or more native species of gooseberries and currants can be domesticated and should some time extend the culture of these fruits from the Gulf of Mexico to the Arctic Circle. There are many forms of juneberries widely distributed in the United States and Canada, from which several varieties are now cultivated. The elderberry is represented by a dozen or more cultivated varieties, one of which, brought to my attention the past season, produced a half hundred enormous clusters, a single cluster being made up of 2,208 berries, each ⅓ inch in diameter.

"These are but a few of the fruits—others which can only be named are: the anonas and their kin from Florida; the native crab-apples and thorn-apples; the wine-berry, the buffalo-berry and several wild cherries; the cloud-berry, prized in Labrador; the crow-berry of cold and Arctic America; the high-bush cranberry; native mulberries; opuntias and other cacti for the deserts; the paw-paw, the persimmon, and the well-known and much-used salal and salmon berries of the West and North.

"The pecan, the chestnut and the hickory-nut are the only native nuts domesticated, but some time forest and waste places can be planted not only to the nuts named, but to improved varieties of acorns, beech-nuts, butternuts, filberts, hazels, chinquapins and nut-pines, to utilize waste lands, to diversify diet and to furnish articles of food that can be shipped long distances and be kept from year to year. The fad of today which substitutes nuts for meat may become a necessity tomorrow. Meanwhile it is interesting to note that the pecan has become within a few decades so important a crop that optimistic growers predict in another half-century that pecan groves will be second only to the cotton-fields in the South. A recent bulletin from the United States Department of Agriculture describes sixty-seven varieties, of which more than 1,500,000 trees have been planted."

"There are a number of native vegetables worth cultivating. The native beans and teparies in the semi-arid and subtropical Southwest to which Freeman, of the Arizona station, has called attention, grown perhaps for thousands of years by the aborigines, seem likely to prove timely crops for the dry-farmers of the Southwest. Professor Freeman has isolated seventy distinct types of these beans and teparies, suggesting that many horticultural sorts may be developed from his foundation stock. The ground-nut, *Apios tuberosa*, furnished food for the French at Port Royal in 1613, and the Pilgrims at Plymouth in 1620, and as a crop for forests might again be used. There are a score or more species of Physalis, or ground-cherries, native to North America, several of which are promising vegetables and have been more or less used by pioneers. *Solanum nigrum*, the nightshade, a cosmopolite of America and Europe, recently much advertised under several misleading names, and its congener, *Solanum triflorum*, both really wild tomatoes, are worthy of cultivation and in fact are readily yielding to improvement. *Amaranthus retroflexus*, one of the common pig-weeds of gardens, according to Watson, is cultivated for its seeds by the Arizona Indians. In China and Japan the corms or tubers of a species of Sagittaria are commonly sold for food. There are several American species, one of which at least was used wherever found by the Indians, and under the name arrowhead, swan potato and swamp potato has given welcome sustenance to pioneers. Our native lotus, a species of Nelumbo, was much prized by the aborigines, seeds, roots and stalks being eaten. Sagittaria and Nelumbo furnish starting-points for valuable food-plants for countless numbers of acres of water-covered marshes when the need to utilize these now waste-places becomes pressing."

Early general writings.

The progress of horticulture may be traced in the books devoted to the subject. The earliest writings did not separate horticulture from agriculture.

It is difficult to determine the first North American book on agriculture. In 1710 "The Husbandman's Guide" was printed in Boston "by John Allen, for Eleazar Phillips." It is a small 12mo of 107 pages, in four parts. The first part contains "Many Excellent Rules for Setting and Planting of Orchards, Gardens and Woods, the times to Sow Corn, and all other sorts of Seeds." A second edition was "printed for & sold by Elea. Phillips Book-seller, in Boston, 1712." It is usual to begin the history of indigenous American book literature on agriculture with Jared Eliot, but the beginnings should have a special search. The preface to Eliot seems to indicate that he knew no writings applicable to North America. The "Essays upon Field-Husbandry," by Rev. Jared Eliot, of Killingworth, Connecticut, grandson of the famous apostle Eliot, were begun in 1748 and completed in 1759. (See "Cyclopedia of American Agriculture," Vol. IV, pp. 568, 569.) "There are sundry books on husbandry wrote in England," said Eliot, in his preface. "Having read all on that subject I could obtain; yet such is the difference of climate and Method of Management between them and us, arising from Causes that must make them always differ, so that those Books are not very Useful to us. Besides this, the Terms of Art made use of are so unknown to us, that a great deal they Write is quite unintelligible to the generality of New England Readers."

Just at the close of the Revolution, J. Hector St. John's "Letters from an American Farmer" appeared, although "the troubles that convulsed the American colonies had not broken out when . . . some of the . . . letters were written." For a period of twenty-five years following the close of the war the condition of our agriculture, and of all American institutions, was minutely unfolded to the world through the writings of many travelers, English and French, who made inquisitive journeys into the new country. Strickland, an English traveler, wrote in 1801 that "land in America affords little pleasure or profit, and appears in a progress of continually affording less. . . . Land in New York, formerly producing twenty bushels to the acre, now produces only ten. . . . Little profit can be found in the present mode of agriculture of this country, and I apprehend it to be a fact that it affords a bare subsistence. . . . Decline has pervaded all the states." There is abundant evidence, including a painstaking inquiry made by Washington, to show that agriculture was at a low state at the close of the century. It was in striking contrast to its status a hundred years later, notwithstanding the pessimistic writings of the later time.

There was early development of the garden desire in the South as well as in the North. In South Carolina appeared the earliest American horticultural book of which we have any record. This book is no longer extant, and it is known to this generation chiefly or wholly from the following page in Ramsay's "History of South Carolina," 1809: "The planters of Carolina have derived so great profits from the cultivation of rice, indigo [see *Indigo*] and cotton that they have always too much neglected the culture of gardens. The high price of their staple commodities in every period has tempted them to sacrifice convenience to crops of a marketable quality. There are numbers whose neglected gardens neither afford flowers to regale the senses, nor the vegetables necessary to the comfort of their families, though they annually receive considerable sums in money for their crops sent to market. To this there have been some illustrious exceptions of persons who cultivated gardens on a large scale, both for use and pleasure. The first that can be recollected is Mrs. Lamboll, who, before the middle of the eighteenth century, improved the southwest extremity of King Street [Charleston], in a garden which was richly stored with flowers and other curiosities of nature, in addition to all the common vegetables for family use. She was followed by Mrs. Logan and Mrs. Hopton, who cultivated extensive gardens in Meeting, George and King Streets, on lands now covered with houses. The former reduced the knowledge she had acquired by long experience and observation to a regular system, which was published after her death, with the title of 'The Gardener's Kalendar;' and to this day regulates the practice of gardens in and near Charlestown." Ramsay records that Mrs. Martha Logan was the daughter of Robert Daniel, one of the last proprietary governors of South Carolina. "Mrs. Logan was a great florist, and uncommonly fond of a garden. She was seventy years old when she wrote her treatise on gardening, and died in 1779, aged seventy-seven years."

Mrs. Logan's book was perhaps only a pamphlet. The first regular American gardening book, if Mrs. Logan's is excluded, is apparently Robert Squibb's "Gardener's Kalender," published in Charleston, South Carolina, in 1787 (see pp. 1520–1).

The opening of the nineteenth century may be taken as a convenient starting-point for a narrative of the evolution of American horticulture. At that time horticulture began to attain some prominence as distinct from general agriculture, and the establishment of peace after the long and depleting war with England had turned the attention of the best citizens afresh to the occupation of the soil. The example of Washington, in returning to the farm after a long and honorable public career, no doubt exerted great influence. His agricultural correspondence was large, and much of it was published at the opening of the century. His correspondence with Arthur Young and Sir John Sinclair will be found in volumes published in London in 1800 and 1801, in Alexandria in 1803, and in Washington in 1847. Details respecting the management of his plantations comprise Vol. IV of the "Memoirs of the Long Island Historical Society," 1889.

Apparently, it was not until 1790 that an indigenous and distinctly general agricultural treatise after Eliot's appeared in America. At that time, the Rev. Samuel Deane, vice-president of Bowdoin College, published his "New England Farmer, or Georgical Dictionary," a cyclopedic work of the state of American agriculture. This passed to a second edition in 1797, and to a third in 1822. As showing both the contents of this important book and the methods of reviewing of that day, the following comment is transcribed from the "Columbian Centinel," for 16th of June, 1790, printed in Boston. It is in the guise of a communication from a correspondent, as was then the custom. It must be one of the earliest reviews of an agricultural book to appear in this country:

> "Nothing has been more wanting in this Country than a book of Practical Husbandry. The late Dr. Elliot of Connecticut wrote some short essays, which were well received, but it was reserved for Mr. Deane, of Portland, to give the publick *a System of Husbandry for New England*. This valuable book is now published and on perusal exceeds the expectation which had been formed of it. It is founded on solid principles of natural philosophy and practical experiment. All that is valuable in European books of husbandry is selected and accommodated to the climate and seasons of this country. Many new and curious observations are introduced; and the whole is cast in such a form and expressed in such language as must render it useful to the plain husbandman, while the enlightened naturalist will find it an agreeable entertainment.
>
> "It not only contains a general system of agriculture, but treats of everything which usually falls under the care of the husbandman and his family, such as cattle, horses, sheep, bees, timber—gives the best directions for the care of the garden, the dairy and the cellar—and much of what is said may be extremely useful in all families where bees, cyder, fruit, milk and other necessary articles are preserved. In short it is a book which does honor to the ingenuity, and industry of its author, and deserves to be read by every person who wishes well to the best interest of this country."

In the Georgetown, South Carolina, "Gazette," March 13, 1799, is a half-column of proposals for publishing by subscription "'Notes on Agriculture adapted to the soil, climate, and markets of South Carolina,' by Louis DuPre. To be put to press as soon as 200 copies are subscribed for. Price one dollar specie." (See page 1520.)

In 1799, J. B. Bordley published in Philadelphia "Essays and Notes on Husbandry." Other early works need not be mentioned here. As early as 1785, Varlo's "New System of Husbandry" was printed in Philadelphia. It is in many ways a remarkable book, and it was written by a man who had had remarkable experiences. He was not an American, and the work first appeared in the old country; but Varlo had lived in this country, and was in sympathy with the American people. The book contained a "Farmer's and Kitchen Garden Calendar." In 1792 there appeared anonymously, from Burlington, New Jersey, the third edition of Arthur Young's "Rural Economy." He argues strongly for experiments and for the establishing of agricultural journals. This book first appeared in London, in 1770.

At the opening of the century (1800), Sir Humphry Davy had not illumined the science of agricultural chemistry, and men were even disputing as to what the food of plants is. The "burn-baking" or "devonshiring" of the land—burning the sod and scattering the ashes over the field—was still recommended; and in 1799 James Anderson's "Essays on Quick-lime as a Cement and as a Manure," was given an American edition in Boston. It is easy to see from these facts that the fundamental conceptions of the science of agriculture were vague and crude a century ago. Near the close of the 18th century, Deane wrote that "the alarming effect of the present low state of husbandry is, that we are necessitated to import much of our food and clothing, while we are incapable of making proportionable remittances in the produce of the soil, or in anything else."

Green's book on flowers, published in Boston in 1828, enables us to determine what were the leading ornamental plants in that early day. The full title of the book is "A Treatise on the Cultivation of Ornamental Flowers; Comprising Remarks on the Requisite Soil, Sowing, Transplanting, and General Management; with Directions for the General Treatment of Bulbous Flower Roots, Greenhouse Plants, etc." It comprises only sixty pages. The introductory pages give general directions, then follow two annotated lists, one of annuals and biennials and the other of greenhouse plants. These lists are interesting, also, for what they do not contain. All the plants they mention are here set down, under the names and with the spelling there employed:

ANNUAL AND BIENNIAL FLOWERS.

Althæa frutex.
Almond, double-flowering.
Amaranthus superbus.
Amaranthus tricolor.
Animated oats.
Aster, China.
Auricula.
Azalea nudiflora.
Box.
Brier, Sweet.
Canterbury Bell.
Carnation.
Cassia marylandica.
Catalpa.
Cherry, double-flowering.
Chrysanthemum indicum.
Clematis, Austrian (C. integrifolia).
Clethra.
Columbine.
Convolvulus.
Corchorus japonicus.
Crocus.
Cupid's Car, or Monk's Hood (Aconitum).
Dahlia.
Daisy.
Dwarf Basil.
Egg Plant.
Eupatorium, blue.
Euphorbia Lathyris.
Fading Beauty, or Morning Bride (Scabiosa).
Fir (Pinus balsamea).
Foxglove.
Fringe Tree.
Geranium (Pelargonium).
Garden Angelica.
Glycine, cluster-flowering.
Golden Coreopsis.
Golden Everlasting (Xeranthemum, lucidum).
Hollyhock.
Honeysuckle.
Hyacinth.
Hydrangea.
Ice Plant.
Impatiens Balsamina.
Iris.
Lagerstrœmia indica.
Laurel, broad-leaved (Kalmia latifolia).
Laburnum.
Larkspur.
Lilac.
Lily.
Lime Plant (Podophyllum peltatum).
Lychnadia (Phlox).
Mezereon (Daphne mezereum).
Mountain Ash.
Musk Geranium.
Myrtle, evergreen (Vinca minor).
Narcissus.
Nasturtium.
Passion Flower.
Pæony.
Pea, sweet.
Peach, double-flowering.
Pink.
Perennial Sunflower, double.
Polyanthus.
Pyrethrum parthenium.
Poppy.
Purple Hyacinth Bean.
Roses.
Rose Acacia.
Rose-colored Hibiscus.
Rudbeckia.
Scarlet Cacalia.
Scarlet Lynchis (L. chalcedonica).
Siberian Crab.
Snow-ball Tree.
Snowberry.
Spice-wood (Laurus Benzoin).
Spiderwort (Tradescantia).
Spiræa.
Syringa, or Mock Orange.
Strawberry Tree (Euonymus).
Sweet Bay (Laurus nobilis).
Sweet William, or Poetic Pink.
Tulip.
Venetian Sumac, or Fringe Tree.
Violet, blue fragrant.

GREEN HOUSE PLANTS.

Lilies of the valley.
Ranunculuses.
Anemones.
Single and Double Jonquils.
White Lilies.
Roses.
Tuberoses.
Persian Iris.
Mignionette.
Verbena trifoliata, or Sweet Vervain.
Fuhsia coccinea.
Cobæa scandens.
Camellia japonica, or Japanese Rose.
Myrtles (Myrtus communis).

These lists are much less ample than those of M'Mahon, over twenty years earlier, but they may be supposed to include the popular and most easily grown things. They will be suggestive to those who wish to make "old-fashioned gardens." M'Mahon's list was evidently largely compiled from European sources. Green says that the first list (strangely called "annual and biennial flowers") contains "such plants, shrubs and trees as are of easy cultivation, generally hardy." The second list comprises "a few different sorts of green house plants" "which are commonly grown in rooms."

The early writings clearly portray the tendencies of the floricultural interests,—from the formal-flower ideals of the dahlia and camellia to the enormous development of the cut-flower interest, and the growth within the last few years of the greater love of plants themselves. Palms and decorative plants are now almost household necessities, whereas seventy-five years ago they would have been luxuries. "There has been a radical change in the character of the flowers used for cut-flower purposes," wrote Alfred Henderson in 1895. "Fifty years ago, camellia flowers retailed freely for a dollar each, and during the holidays Philadelphia used to send thousands to New York florists, getting $500 per 1,000; while roses went begging at one-tenth these figures. Now, the rose is queen, and the poor camellia finds none so poor to do her reverence. . . . . I confidently believe that the time is not far distant when we shall compete seriously with the foreign grower in the production of new varieties of roses." William Scott, of Buffalo, in 1900 made the following comments on floriculture: "About the year 1880, tulips and narcissuses began to be forced, and during the next fifteen uears immense quantities of these bulbs were imported annually from Holland. As the methods of forcing were perfected the market became overstocked, and, although large quantities are still forced for the winter and spring months, they are not now in the same favor as formerly, and the rose, carnation, violet, lily-of-the-valley and mignonette are still the favorites. Orchids are not yet the flower for the million, but there is a yearly increasing demand for them, and at present the showy orchids, such as the Cattleyas and Lælias, are far short of the demand. As their cultivation is more generally understood, we look for a very steady increase in the number grown, and are confident that the supply will not soon exceed the demand. Within the past five or six years a marked increase is noticeable in the use of plants to adorn the home, and the demand is for an expensive class of plants,—palms, dracenas, araucarias and ferns being among those mostly used. Now few homes with any pretension to luxury or even comfort are without a few fine plants scattered through the rooms, and many of our modern houses are provided with either a bay window or small conservatory for the accommodation of plants." (See *Cut-Flower Industry* and *Floriculture.*)

America has not been favored with horticultural annuals to the extent equally with England and other countries. The first attempt of the kind seems to have been Woodward's "Record of Horticulture," edited by A. S. Fuller, which appeared in 1866 and 1867. The next venture was the "American Horticultural Annual," New York, for the years 1868 ,1869 and 1870, under the general editorial care of George Thurber. The attempt was not made again until the "Annals of Horticulture," was issued by Bailey, in 1889, and which was published for five years, the last volume containing an account of the horticulture of the Columbian Exposition.

Fruit-growing in particular.

Horticulture, in its commercial aspects, was nothing more than an incidental feature of farm management at the opening of the century. In fact, it is only in the past generation that the field cultivation of horticultural crops has come to assume any general importance in the rural economy of the nation. And even now, horticultural operations which are projected as a fundamental conception of land occupation are confined to relatively few parts of the country. It is only in certain regions or with certain persons that the farmer starts out with horticulture as a base, and with grain and stock and hay as accessories; and even in these places, many horticulturists are still drawing their practices and the reasons for them from the operations of general mixed agriculture. The history of fruit-growing in most of the older parts of North America is the history of the apple, and the subject is developed under that heading; but before proceeding to the apple specially we may pause to consider some of the dates in the extension of fruit-growing westward.

"It may not occur to many of our people," writes Charles W. Garfield, "that the horticulture of Michigan may have had its beginning as early as that of Massachusetts, as the French Jesuit missionaries visited Detroit the same year that the Mayflower landed its pilgrims at Plymouth Rock." The influence of the French missionaries must be well considered when the history of American horticulture is written, particularly of those parts that lie along the great waterways. The old pear trees along the Detroit River and in eastern Michigan attest the early French dissemination. The first planting of orchards in Michigan, according to Garfield, "were made at Detroit from stock secured across the river, the stock having originally come from France to Montreal, and progressed westward with the settlements. The varieties were Fameuse, Pomme Grise, and Red and White Colville." The first large importation of orchard trees was made about 1825, the stock having come from Grant Thorburn of New York. The spread of tree-planting to the westward followed regularly with the progress of settlement.

The above remarks about the Jesuits indicate that the early American fruit-growing was not all derived from British sources. Much of the influence was certainly French; on the Pacific coast and probably in parts on the southern borders of the present United States it was Spanish. It would be interesting to try to trace the influence of the Dutch and other colonizers.

The reader who desires to trace the beginnings of fruit-planting in some of the territory from Nebraska south and southwest should consult the "Proceedings of the American Pomological Society" for 1905 (pages 74-98). In Nebraska, apples were planted in 1853. It appears that in Kansas apple-tree planting has been recorded near Shawneetown, Johnson County, as early as 1827 by Rev. Thomas Johnson, the variety being the Newtown Pippin. In 1836, he planted pear trees. In Arkansas, J. B. Russell, of Cane Hill, had a small nursery of apple trees in 1835. A little after this date, Isaac Shannon originated the apple that bears his name. Before the close of the seventeenth century, the French at St. Genevieve, Missouri, had planted pears, grapes and a few apples. In New Mexico, the agricultural industry developed to some extent under Spanish rule, and continued under the Mexican rule from 1822 to 1845, but little reference is made to fruit. It is recorded that the Bishop of Santa Fé, early introduced apricots and apples from the States, and John Clark planted apple trees from Missouri in Rio Arriba County in 1859.

1853. Relic of early days—apple tree at probably 250 years

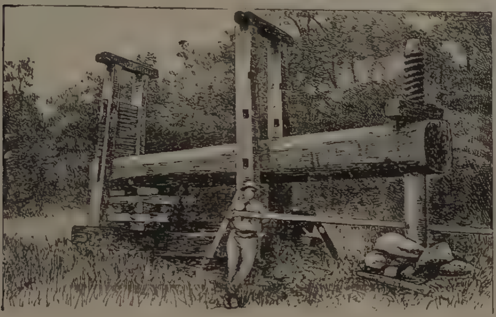
1854. Bartram's cider-mill, a relic of the last century.

It is said that the apples were placed in the circular groove in the rock and crushed by means of a weight rolling over them. The juice ran out the gutter at the farther side and was caught in a rock-hewn cistern.

The development of fruit-growing in the Northwest is sketched for this occasion by C. I. Lewis. The first authentic introducton of fruit into the Pacific Northwest (of the United States) was in 1824, when seed was brought from England by members of the Hudson Bay Company. This seed was planted near what is now Vancouver, Washington, then a trading-post of the Hudson Bay Company. Seeds of apples, grapes, pears, and peaches were planted. The apple trees which resulted from this seed are still standing on government lands occupied by the Vancouver barracks. There were other introductions by various persons, but they probably had no influence on the growth of the fruit industry in the Northwest. In 1847, Henderson Lewelling, of Iowa, brought several hundred yearling grafted sprouts of mixed fruits. The same year William Meek brought a sack of apple seed and a few grafted trees. These two men established the first nursery in the Pacific Northwest at Milwaukee, Oregon, and laid the foundation of our commercial fruit industry. In the following ten or fifteen years, many men brought trees and seed, and nurseries were started. From 1850 to 1870, fabulous prices were received for fruit, one box of apples selling for $75, while in 1855, 6,000 bushels of apples sold for prices ranging between $20 and $30 a bushel. The period between 1850 and 1870 also marked the introduction of plums and prunes into the Northwest country. The first Italian prune orchard was set in 1858 by Seth Lewelling. Between 1870 and 1890 was a period of decline. The former demand from California ceased and railroads were few, the freight rates being exorbitant. Beginning early in the 1890's the fruit industry of the Northwest began to revive. About 1900, the apple industry began to recover. In 1896, the Lambert cherry was introduced commercially, and has proved to be the greatest commercial cherry for shipping. J. R. Cardwell has been the principal historian of Northwest horticulture. He came out in the early days of the fruit industry and is still living. He has been very influential in building up the fruit industry in the Pacific Northwest.

The apple.

There was practically only one general horticultural commodity, at least in the northern states, a hundred years ago, and that was the apple. Pears, peaches, cherries, quinces and some other fruits were common, but there was little thought of marketing them. Even the apple was an incidental or even an accidental crop. Little care was given the trees, and the varieties were few, and they were rarely chosen with reference to particular uses, beyond their adaptability to cider and the home consumption. In parts of the East, very ancient apple-tree relics still stand, some of them perhaps existing from Colonial times (Fig. 1853).



1855. An early cider-mill in Pennsylvania.

Thacher, writing from Plymouth in 1821, says that "the most palpable neglect prevails in respect of proper pruning, cleaning, and manuring round the roots of trees, and of perpetuating choice fruits, by engrafting from it on other stocks. Old orchards are, in general, in a state of rapid decay; and it is not uncommon to see valuable and thrifty trees exposed to the depredations of cattle and sheep, and their foliage annoyed by caterpillars and other destructive insects. In fact, we know of no branch of agriculture so unaccountably and so culpably disregarded." Were it not for the date of Thacher's writing, we might mistake this picture for one drawn at the present day.

If one may judge from the frequent and particular references to cider in the old accounts, it does not seem too much to say that this sprightly commodity was held in greater estimation by our ancestors than by ourselves. In fact, the cider barrel seems to have been the chief and proper end of the apple. Of his thirty chapters on fruit-growing, Coxe (1817) devotes nine to cider, or forty-two pages out of 253. John Taylor's single epistle devoted to horticultural matters in the sixty and more letters of his "Arator" is upon "Orchards," but it is mostly a vehement plea for more cider. "Good cider," he says, "would be a national saving of wealth, by expelling foreign liquors; and of life, by expelling the use of ardent spirits." In Virginia, in Taylor's day, apples were "the only species of orchards, at a distance from cities, capable of producing sufficient profit and comfort to become a considerable object to a farmer. Distilling from fruit is precarious, troublesome, trifling and out of his province. But the apple will furnish some food for hogs, a luxury for his family in winter, and a healthy liquor for himself and his laborers all the year. Independent of any surplus of cider he may spare, it is an object of solid profit and easy acquisition." As early as 1647, twenty butts of cider were made in Virginia by one person, Richard Bennet. Paul Dudley writes of a small town near Boston, containing about forty families, which made nearly 3,000 barrels of cider in the year 1721; and another New England town of 200 families, which supplied itself with "near ten Thousand Barrels." Bartram's cider-mill, as it exists at the present day, is shown in Fig. 1854. An old mill in Pennsylvania is shown in Fig. 1855. It is a ponderous pine log, more than three feet through, raised and lowered by means of a great screw. "These presses" according to C. F. Shaw, "were 'neighborhood' affairs in cider-making time and the farmers would rise very early that they might reach the press before their neighbors, and so not have to wait long before their turn to have their cider made." It was not until well into the past century that people seem to have escaped the European notion that fruit is to be drunk. Jarvis writes (1910) of Connecticut conditions that in "the first half of the last century many commerical orchards of modest size were in existence, but they were composed mostly of seedling trees or 'native fruit,' the product of which was used largely in the manufacture of cider."

There have been several marked alternations of fervor and neglect in the planting of apples since the first settlement of the country. Early in the eighteenth century there appears to have been a great abundance of the fruit; but in 1821 Thacher declared that "it is a remarkable fact that the first planters bequeathed to their posterity a greater number of orchards, in proportion to their population, than are now to be found in the old colony," and he attributes the decline in orcharding largely to the encroachment of the "poisonous liquor" of the later times. Under the inspiration of Thacher, Coxe, Kendrick, Prince, Manning, and the Downings, orchards were again planted, and later there was another period of decline in the East, following the aging of these plantations. Two reminders of the Downings are shown in Figs. 1856 and 1857, made from photographs taken by the writer some twenty or more years ago.

Apple trees were very early planted in the New World. On Governor's Island, in Boston harbor, a few apples were picked in 1639. Trees were carried far into the frontiers by the Indians and probably also by the French missionaries, and the "Indian apple orchards" are still known in many localities even east of the Mississippi (see, also, *Appleseed, Johnny* page, 1563). At the opening of the nineteenth century, the Early Harvest, Newtown Pippin, Swaar, Spitzenburg, Rhode Island Greening, Yellow Bellflower, Roxbury Russet, and other familiar apples of American origin were widely disseminated and much esteemed. Apples had begun to be planted by settlers in Ohio before 1800. In 1817, Coxe could recommend a list of "one hundred kinds of the most estimable apples cultivated in our coun-

1856. One of the old Downing test apple trees as it stood about 25 years ago.

try;" and in 1825 William Prince offered 116 varieties for sale—at 37½ cents a tree—of which seventeen were set aside—after the custom of the time—as particularly adapted to the making of cider. Of these 116 varieties, sixty-one were considered to be of American origin. In 1872, Downing's list of apples which had been fruited and described in America, had swollen to 1,856 varieties, of which 1,099 were of known American origin. Of this great inventory, probably not over one-third were actually in cultivation at any one time, and very many of them are now lost. In 1892, the trade-lists showed that 878 varieties were actually offered for sale by the nurserymen of North America.

1857. The fruit-house of Charles Downing.

The style of illustration in these old books is well displayed in Fig. 1858, from Coxe, original size.

There has been a noticeable tendency toward the origination of varieties of apples in this country, and the consequent exclusion of varieties of European origin. As early as 1760, cions of American varieties were sent to England. Before the Revolution, apples were exported. The origination of indigenous varieties was, of course, largely accidental, and was a necessary result of the method of growing apple trees directly from seeds, and top-grafting them in case they should turn out profitless. A critical study of American horticulture will show that all species of plants which have been widely cultivated in this country have gradually run into indigenous varieties, and the whole body of our domesticated flora has undergone a progressive evolution and adaptation without our knowing it. By far the greater number of the apples of the older apple-growing regions of the country are indigenous varieties, and the same process is now operating in the Northwest, where the American seedlings of the Russian stock are proving to be more valuable than the original importations.

Pears were amongst the earliest fruits introduced into the New World, and the French, particularly, disseminated them far and wide along the waterways, as witnessed by the patriarchal trees of the Detroit River and parts of the Mississippi system (p. 1512). Bartram's Petre pear (Fig. 1851) is one of the patriarchs of the last century, although the tree is not large. The first American book devoted exclusively to the pear was Field's, published in 1859. The Japanese type of pears had been brought into the country from two and perhaps three separate introductions, early in the fifties, but they had not gained sufficient prominence to attract Field's attention. From this oriental stock has come a race of promising kinds represented chiefly by the Kieffer, LeConte and Garber.

Peaches were early introduced into the New World by various colonists, and they thrived so well that they soon became spontaneous. Nuttall found them naturalized in the forests of Arkansas in 1819, and the species now grows in waste and forest lands from Georgia and the Carolinas to the westward of the Mississippi. There is probably no country in which peaches grow and bear so freely over such a wide territory as in North America. The old Spanish or Melocoton type is now the most popular race of peaches, giving rise to the Crawfords and their derivatives.

Of late years there has been a contraction of some of the original peach areas, and many good people have thought that the climate is growing uncongenial, but it is only the natural result of the civilization of the country and the change in methods. Peaches had never been an industry, but the orchards were planted here and there as very minor appendages to the general farming. For generations insect pests were not common. There were no good markets, and the fruit sold as low as 25 cents a bushel from the wagon-box. In fact, the fruit was grown more for the home-supply than with an idea of shipping it to market. Under such conditions, it did not matter if half the crop was wormy, or if many trees failed and died each year. Such facts often passed almost unnoticed. The trees bore well, to be sure; but the crop was not measured in baskets and accounted for in dollars and cents, and under such conditions only the most productive trees left their impress on the memory. The soils had not undergone such a long system of robbery then as now. When the old orchards wore out, there was no special incentive to plant more, for there was little money in them. Often the young and energetic men had gone West, there to repeat the history perhaps, and the old people did not care to set orchards. And on this contracting area, all the borers and other pests which had been bred in the many old orchards now concentrated their energies, until they have left scarcely enough trees in some localities upon which to perpetuate their kind. A new country or a new industry is usually free of serious attacks of those insects that follow the crop in older communities. But the foes come in unnoticed, and for a time spread unmolested, when finally, perhaps almost suddenly, their number becomes so great that they threaten destruction, and the farmer looks on in amazement.

Oranges.—The orange is another tree that has thrived so well in the new country that the spontaneous thickets of Florida, known to be descendants of early Spanish introductions, are supposed by residents to be indigenous to the soil.

As to oranges and similar fruits on the Pacific coast, Coit writes in "Citrus Fruits" (1915) as follows: "Citrus seeds were first brought into California from the peninsula of Lower California, where peoples of Spanish descent have cultivated various kinds of European fruit trees and vines since the year 1701. In 1768 the Jesuit missionaries were supplanted by the Franciscans, some of whom under the leadership of Junipero Serra pushed northward into the territory which is now the state of California. These hardy pioneers founded the first Mission in Upper California at San Diego in 1769, and proceeding northward established a chain of Missions extending 400 miles along the coast, the last being established at Somoma in 1823."

Plums and cherries.—The progress of the plum in America nearly equals that of the grape in historic interest. The small spontaneous plums, known as

Damsons, the offspring of introductions from Europe, were early abundant in New England. Plum-culture has never thrived far south of Mason and Dixon's line or west of Lake Michigan, except, of course, on the Pacific slope and parts of the far southwestern country. There are climatic limitations which more or less restrict the area of plum-growing, and [illegible] leaf-blight fungus, black-knot, and fruit-rot have added to the perplexities. In these great interior and southern areas various native plums, offshoots of several indigenous species, have now spread themselves, and they have already laid the foundation of a new type of plum-culture. The first of these novel plums to receive a name was that which we now know as the Miner, and the seed from which it sprung was planted by William Dodd, an officer under General Jackson, in Knox County, Tennessee, in 1814. The second of these native plums to come into prominence, and the one which really marks the popularization of the fruit, is the Wild Goose. Some time before 1830, it is related, a man shot a wild goose near Columbia, Tennessee, and where the remains were thrown this plum sprang forth. It was introduced to the trade about 1850, by the late J. S. Downer, of Fairview, Kentucky. Over 200 named varieties of these native plums are now described, and some of them are widely disseminated and deservedly popular. In the South and on the plains, these natives are a prominent horticultural group. The complexity of the cultivated plum flora is now further increased by the introduction of the Japanese or Chinese type, which first came in by way of California in 1870. Finally, about 1880, the apricot plum, or *Prunus Simonii*, was introduced from China by way of France; and the American plum industry, with no less than ten specific types to draw upon and which represent the entire circuit of the northern hemisphere, is now fairly launched upon an experimental career which already has produced remarkable results.

The cherry was early introduced from Europe. In 1641 trees were planted in Virginia in the orchard of Governor Berkeley. As early as 1663 it was grown in Massachusetts. The commercial cherries of this country are derived from the same species as those of Europe, although the dwarf sand-cherry of the Plains has been improved or cultivated to some extent.

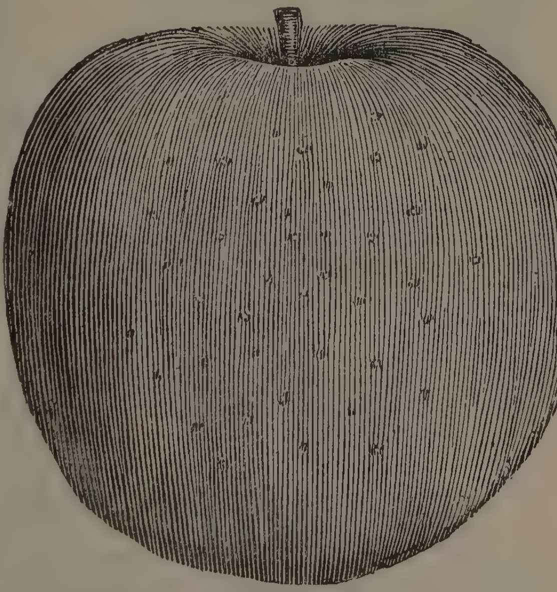
Grapes.—In America, no crop has been the subject of so much book-writing as the grape. Counting the various editions, no doubt a hundred books have appeared, being the work of at least fifty authors. Since the American grape is a product of our own woods within about a century, the progress in grape-growing has been ahead of the books. Most of the books are founded largely on European advice, and therefore are not applicable to American conditions. In general pomology, the books seem to have had much influence upon fruit-growing; but in the grape the books and actual commercial grape-growing seem to have had little relation one to the other. Some of the later books have more nearly caught the right point of view.

The grape of North America is of two unlike types,—the natives, which comprise all commercial outdoor varieties in the interior and eastern states; and the vinifera or Old World kinds, which are grown under glass and in California. The native types were developed within the nineteenth century. The oldest commercial variety is the Catawba, which dates from 1802; the cosmopolitan variety the Concord, which first fruited in 1849 (see p. 1374). A full review of the history is made in "Evolution of Our Native Fruits." With the first settlement of the country, efforts were made to grow the European wine-grape. Thus in 1619 vine-dressers and vines were sent from France to Virginia; the subsequent history of the wine-grape in North America is a record of repeated attempts and continuous failures; and these failures, due largely to phylloxera and mildew, finally forced the cultivation of the native species of Vitis. In Mexico and on the Pacific slope, however, the wine-grape established itself readily about the missions, and it is now the foundation of the grape-culture of California. It is very likely that these introductions of the padres preceded those in the eastern American colonies.

A very interesting error appears to have crept into North American history in connection with the native grapes. The "wineberry" found by the Norsemen on the American coast in the eleventh century has prevailingly been identified as grapes, and this interpretation has made it apparent that the explorers came south as far as the present New England. Recently, however, M. L. Fernald has concluded (Rhodora, xii, 17–38, Feb., 1910), that the wineberries of the Norsemen were certainly not grapes, but most likely the mountain cranberry, *Vaccinium Vitis-Idæa.*

To show how far we have come in grape-culture, the examples in Fig. 1859 will be interesting. This cut is from S. W. Johnson's "Rural Economy," 1806, published in New Jersey. It shows the method with the European wine-grape. Just twenty years later appeared Dufour's book on the grape; he also represents a foreign method (Fig. 1860).

Strawberry.—There was no commercial strawberry-culture in America, worthy of the name, until the introduction of the Hovey (Fig. 1861) late in the thirties of last century. This and the Boston Pine were seedlings of C. M. Hovey's, Cambridge, Massachusetts. They first fruited in 1836 and 1837, and from them are supposed to have descended many of the garden strawberries of the present day. These were seedlings of the old Pine type of strawberry, which is apparently a descendant of the wild strawberry of Chile. The Wilson, or Wilson's Albany, which originated with John Wilson, of Albany, New York, began to attract attention about 1856 or 1857, and it marked the beginning of the modern epoch in American strawberry-growing. In the Middle West, strawberry-growing was given a great impulse by Longworth and Warder.



1858. Example of the earliest illustrations of American fruits.
Esopus Spitzenberg, figured by Coxe in 1817.

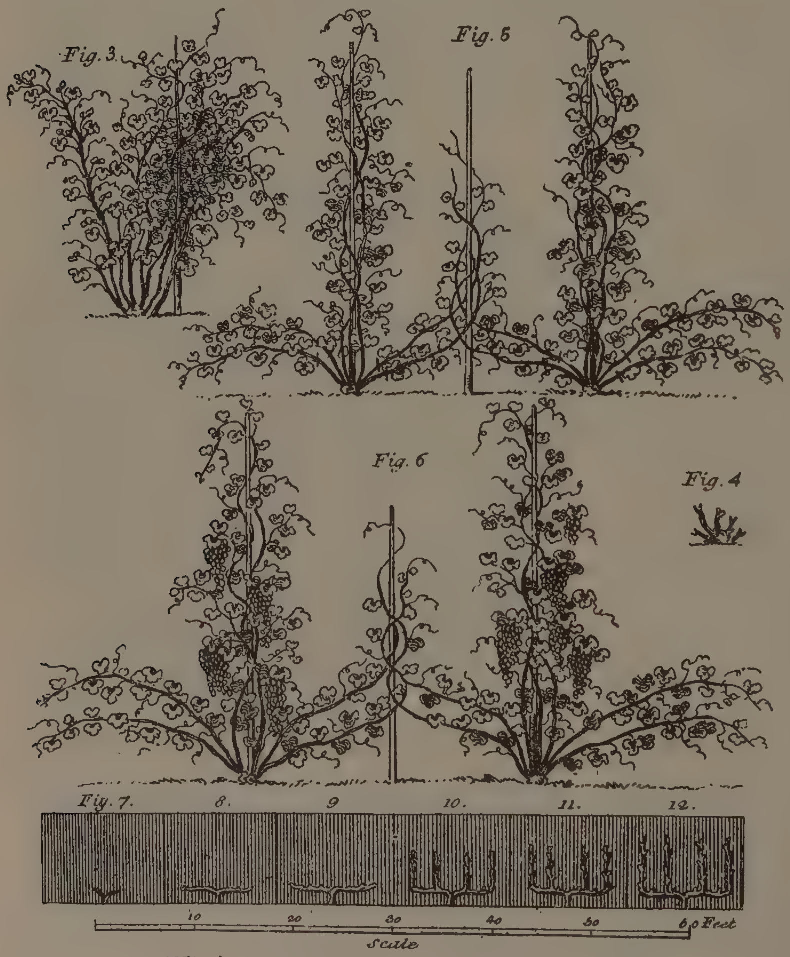
Bramble fruits.—Raspberries were grown in North America in the eighteenth century, but they were of the tender European species, of which the Antwerps were the common types. This type of raspberry is now almost wholly superseded by the offspring of the native red and black species, which first began to impress themselves upon cultivation about 1860.

The blackberry, an indigenous American fruit, first commended itself to cultivation with the introduction of the New Rochelle or Lawton, toward the close of the 1850's. The first named variety of native blackberry of which we have any record was the Dorchester, which was exhibited before the Massachusetts Horticultural Society in 1841.

The dewberry, a peculiarly American fruit, first appeared in cultivation early in the 1870's in southern Illinois under the name of the Bartel, which is a large form of the common wild dewberry of that region. It was first brought to the attention of the public in 1875. The following year the Lucretia, the most popular of dewberries, was introduced into Ohio from West Virginia, where it had been found wild some years before by a Union soldier.

Gooseberries.—The history of the gooseberry in America recalls that of the grape. It is a characteristic fruit of England and the Low Countries, and it was early introduced into America. But, like the European grapes, the gooseberries were attacked by a fungous sickness which rendered the cultivation precarious. An improved form of the native species must be introduced, and this was accomplished by Abel Houghton, of Massachusetts, who, from the seed of the wild berry, produced the variety which now bears his name (Fig. 1862). This variety began to attract some attention a little previous to 1850, although it was not planted freely until several years later. From seed of the Houghton sprang the Downing, still the most popular gooseberry in America, although Houghton is still much grown from Philadelphia south; and our gooseberry-culture is, therefore, but two removes from nature. With the advent of the bordeaux mixture and its related specifics, however, the English gooseberries are again coming to the fore. Hybrids of the English and American types, as in the Triumph or Columbia and the Chautauqua, may be expected to become more popular for home use and special markets, but the Americans will probably remain in favor for general market purposes.

The cranberry, most singular of American horticultural products, was first cultivated, or rescued from mere wild bogs, about 1810. Its cultivation began to attract attention about 1840, although the difficulties connected with the growing of a new crop did not begin to clear away until about 1850. Cape Cod was the first cranberry-growing region, which was soon followed by New Jersey, and later by Wisconsin and other regions. The varieties now known are over a hundred, and the annual product from tame bogs in North America is now upward of 1,000,000 bushels.

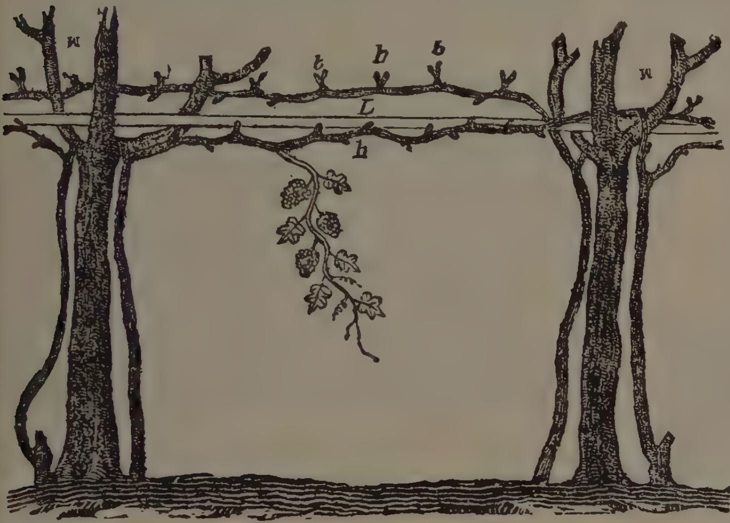


1859. An early American picture of grape-training (1806).

The nursery and seed business.

It is impossible to fix a date for the beginning of the nursery business in North America. Trees were at first grown in small quantities as an adjunct to general farm operations. Gov. John Endicott, of the Massachusetts Colony, was one of the best fruit-growers of his time, and he grew many trees. In 1644, he wrote to John Winthrop as follows: "My children burnt mee at least 500 trees this Spring by setting the ground on fire neere them;" and in 1648 he traded 500 apple trees, three years old, for 250 acres of land. The first nursery in Maine is thought by Manning to have been that of Ephraim Goodale, at Orrington, established early in the present century. Other early nurserymen of Maine were the brothers Benjamin and Charles Vaughan, Englishmen, who settled at Hallowell in 1796. An early nursery in South Carolina was established by John Watson, formerly gardener to Henry Laurens, before the Revolution. In Massachusetts, there were several small nurserymen toward the close of the eighteenth century, amongst others, John Kenrick, of Newtown, whose son William wrote the "New American Orchardist," published in 1833, and which passed through at least eight editions. The trees were usually top-grafted or budded, sometimes in the nursery and sometimes after removal to the orchard. Deane writes in 1797, that "the fruit trees should be allowed to grow to the height of 5 or 6 feet before they are budded or grafted." Stocks were sometimes grafted at the crown, and even root-grafting was known, although it is generally said that this operation originated with Thomas Andrew Knight, in 1811. It is probable, however, that the root-grafting of the eighteenth century was only grafting at the surface of the ground, and that it had little similarity to the method now in vogue.

One of the new trees something over one hundred years ago was the Lombardy poplar. John Kenrick had two acres devoted to it in 1797; and Deane writes, in 1797, that "the Lombardy poplar begins to be planted in this country. To what size they will arrive, and how durable they will be in this country, time will discover." He does not mention it in the first edition, 1790. The tree is said to have been introduced into America by William Hamilton, of Philadelphia, in 1784, although Mr. Meehan wrote that he remembered trees over sixty years ago that seemed to be a century old.



1860. Dufour's picture of grape-training (1826). Patterned after the South-European fashion of employing mulberry trees for supports.

Manning quotes a bill of sale of nursery stock in 1799, showing that the price of fruit trees was 33⅓ cents each. Deane speaks of raising apple trees as follows: "The way to propagate them is by sowing the pomace from cydermills, digging, or hoeing it into the earth in autumn. The young plants will be up in the following spring; and the next autumn, they should be transplanted from the seed-bed into the nursery, in rows from 2 to 3 feet apart and 1 foot in the rows, where the ground has been fitted to receive them." Nothing is said about grafting the trees in the nursery.

The first independent general nursery in the New World, in the sense in which we now understand the term, appears to have been that established by William Prince at Flushing, Long Island, and which was continued under four generations of the same family. The founder was William Prince. The second Prince was also William, the son, and author of the first regular American treatise on horticulture, 1828. The third generation was William Robert Prince. He was the author of "A Treatise on the Vine" (1830), "The Pomological Manual" (1831), and "Manual of Roses" (1846). In the first two he was aided by his father, the second William. This William Robert Prince is the one who first distinguished the types of the prairie strawberry into the two species, *Fragaria illinoensis* and *F. iowensis*. From a large catalogue of William Prince, second, published in 1825—and which contains, amongst other things, lists of 116 kinds of apples, 108 of pears, 54 of cherries, 50 of plums, 16 of apricots, 74 of peaches and 255 of geraniums—the following account is taken of the founding of this interesting establishment: "The Linnæan Garden was commenced about the middle of the last century by William Prince, the father of the present proprietor, at a time when there were few or no establishments of the kind in this country. It originated from his rearing a few trees to ornament his own grounds; but finding, after the first efforts had been attended with success, that he could devote a portion of his lands more lucratively to their cultivation for sale than to other purposes, he commenced their culture more extensively, and shortly after published a catalogue, which, at that early period, contained several hundred species and varieties, and hence arose the first extensive fruit collection in America." The elder Prince died in 1802, "at an advanced age." In October, 1790, a broadside was issued in New York, printed by Hugh Gaine, giving a list of a large collection of fruit trees and shrubs for sale by William Prince at Flushing Landing, on Long Island. The twenty-second edition of this broadside appeared in 1823. In Thomas "History of Printing," second edition, reference is made to an edition printed in 1771.

Amongst the nurseries which were prominent from 1820 to 1830 were Bloodgood's, Floy's, Wilson's, Parmentier's, and Hogg's, near New York; Buel and Wilson's at Albany; Sinclair and Moore's, at Baltimore. David Thomas, a man of great character, and possessed of scientific attainments, was an early horticulturist of central or western New York. His collection of fruits at Aurora on Cayuga Lake, was begun

1861. The original picture of the Hovey strawberry. "Magazine of Horticulture," August, 1840. (Original size)

about 1830. His son, John J. Thomas, nurseryman and author of the "American Fruit Culturist," which first appeared in 1846, died at a ripe old age in 1895. The nursery of Thomas Hogg, referred to above, was an important establishment. In a "Catalogue of the ornamental trees and shrubs, herbaceous and greenhouse plants, cultivated and for sale by Thomas Hogg, nurseryman and florist," 1834, there are sixteen small pages, double columns, of mere lists of species and varieties, comprising no less than 1,200 entries of great variety. These were offered at "The New York Botanic Garden in Broadway, near the House of Refuge." The first Thomas Hogg, an Englishman, procured land in 1822 in upper Broadway (where Twenty-third Street now is), and began business as florist and nurseryman. In 1840 they were removed to Seventy-ninth Street and East River, and here the sons, Thomas and James, assisted the father, who died in 1855. Later, James had a garden at the foot of Eighty-fourth Street, and here he grew many plants sent from Japan, by his brother Thomas, who resided and traveled in that country (page 1580).

1862. The original picture of the Houghton gooseberry. From the "Horticulturist" for September, 1868. (Original size)

The nursery firm of Parsons & Co., on Long Island, was founded in 1838. It was instrumental in distributing great quantities of fruit and ornamental stock at a formative time in American horticulture, and it was a pioneer in several commercial methods of propagation of the more difficult ornamental stock. It was a leading distributor of Japanese plants in the early days. Between 1840 and 1850 arose the beginnings of that marvelous network of nurseries, which, under the lead of Ellwanger & Barry, T. C. Maxwell & Brothers, W. & T. Smith, and others, has spread the name of western New York throughout North America. In 1857, Prosper J. Berckmans, who had then been a resident of the United States seven years, removed to Georgia, and laid the foundation of the very important business now conducted by his sons.

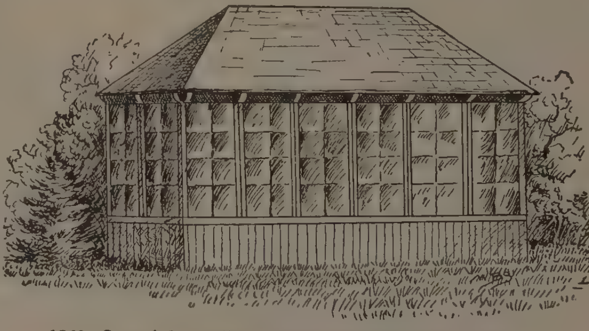
The oldest American seed house, David Landreth's, in Philadelphia, was established in 1784. Another was John Mackejohn's, 1792; others, William Leeson, 1794, and Bernard M'Mahon, 1800, all of Philadelphia. In 1802, Grant Thorburn's was established in NewYork, the first catalogue of four pages being published then. The first and last of these businesses still exist under the family names. M'Mahon did a large business in exporting seeds of native plants, and it was through his work that many American plants came into cultivation in Europe. His catalogue of seeds of American plants in 1804, for the export trade, contained about 1,000 species of trees, herbs and shrubs. He also announced at that time that he had "also for sale an extensive variety of Asiatic, South Sea Islands, African and European seeds of the most curious and rare kinds." "The prices shall be moderate, and due allowance will be made to those who buy to sell again." M'Mahon, through business and writing, had great influence on American horticulture in its formative period. He distributed seeds of the very important Lewis and Clark expedition; but Landreth is said to have shared these seeds, and also those collected by Nuttall. Those were days of the enthusiastic exportation of the seeds of American plants.

The development of the seed trade is coincident with the development of the postal service. Burnet Landreth writes that "it was not until 1775 that the New York city post office was first established, the mail passing once every two weeks between New York and Boston. In 1775, a through mail was established by Postmaster Franklin between Boston and Savannah, the letters being carried by post riders, each man covering 25 miles. Previous to that date, sixty days would frequently pass without a mail from Virginia."

The number of seed firms in North America is now in the hundreds. With the development of the plant-breeding enterprises, local or regional firms and associations are springing up, to do commerce with particular strains or lines of breeding. The demand for good seeds, with recognized merit, is one of the most hopeful developments in American agriculture. It is of the same order of excellence as the demand for pedigreed and well-bred live-stock.

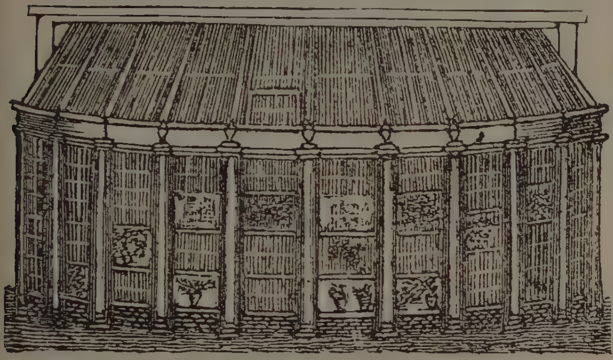
Greenhouses.

The first glasshouse in North America was probably erected early in the century before last, in Boston, by Andrew Faneuil, who died in 1737. This house passed to his nephew, Peter Faneuil, who built Faneuil Hall. The greenhouse which is commonly considered to be the first built in the country was erected in 1764 in New York, for James Beekman. A picture of this, from Taft's "Greenhouse Construction," is shown in Fig.



1863. One of the earliest American greenhouses (1764).

1863. Glasshouses were fully described in 1804 by Gardiner and Hepburn, and in 1806 by M'Mahon, but these authors do not state to what extent such structures existed in America. In Doctor Hosack's botanic garden, 1801, extensive glasshouses were erected. Compare Figs. 1749 and 1750. Fig. 1864 shows one of the earliest American pictures of a greenhouse. It is copied, full size, from Squibb's "Gardener's Calendar," Charleston, South Carolina, 1827. Fig. 1865 shows the first greenhouse in Chicago, as illustrated in "American Florist." Note the small panes, and the sash-construction. This was built in 1835 or 1836. With these pictures should be compared the modern greenhouses as shown in Fig. 1866; also in the pictures in the articles on *Greenhouse*.



1864. Greenhouse front.

With glass lights and door of glass at the end, to be 7 feet high, 35 in length by 12 in breadth. Brick foundation 2 feet high, half a foot of which to be underground.—Robert Squibb, "Gardener's Calendar," Charleston, S. C. (1827).

These early houses were heated by flues or fermenting substances. The use of steam in closed circuits began in England about 1820. Hot-water circulation seems to have been a later invention, although it drove out steam heating, until the latter began to regain its supremacy in this country thirty to forty years ago. The "New England Farmer" for June 1, 1831, contains a description of hot-water heating for hothouses, a matter then considered to be a great novelty.

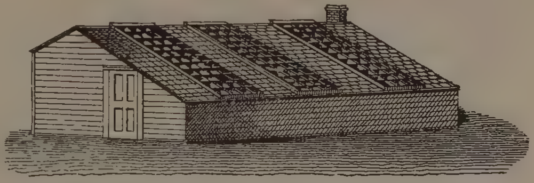
Most of the early houses had very little, if any, glass in the roof, and the sides were high. It was once a practice to build living-rooms over the house, so that the roof would not freeze. In the "modern" construction of the greenhouse of M'Mahon's day, 1806, he advised that "one-third of the front side of the roof, for the whole length of the house, be formed of glass-work," and in order that the tall, perpendicular sides of the house should have as "much glass as possible," he said that "piers between the sashes are commonly made of good timber, from 6 to 8 or 10 inches thick, according to their height." "The width of the windows for the glass sashes may be 5 or 6 feet; . . . the bottom sashes must reach within a foot or 18 inches of the floor of the house and their top reach within 8 or 10 inches of the ceiling." The panes in the roof should be 6 inches by 4, this size "being not only the strongest, but by much the cheapest, and they should lap over each other about ½ inch." But the sides or "front lights must be made with large panes of glass." Many or most of the early plant-houses had removable tops, made of sash. On the change from the old to the new ideas, Alfred Henderson writes as follows: "The first published advocacy of the fixed-roof system was made by Peter B. Mead, in the 'New York Horticulturist,' in 1857. Before that, all greenhouse structures for commercial purposes were formed of portable sashes, and nearly all were constructed as 'lean-tos,' with high back walls, and none were connected. All were separate and detached, being placed at all angles, without plan or system. Then, too, the heating was nearly all done by horizontal smoke-flues, or manure fermenting, although there was a crude attempt at heating by hot water by some private individuals as early as 1833. The first use of heating by hot water on anything like a large scale, however, was in 1839, when Hitchings & Co., of this city, heated a large conservatory for Mr. William Niblo, of New York; and yet for nearly twenty years after this time heating by hot water was almost exclusively confined to greenhouses and graperies on private places, as few professional florists in those days could afford to indulge in such luxuries. All this is changed now. The use of steam, hot water under pressure, and the gravity system of hot-water heating are almost universally in operation, the hot-air flue having been relegated to the past. The best evidence of progress is in the fact that the florist has not waited for the tradesman, but has brought about these improvements himself."

Much attention was early given to the slope of the roof, in order that the greatest amount of sunlight may be secured. Early in the past century the curvilinear roof came into use, as the various angles which it presents to the sun were supposed to catch the maximum number of the incident rays. The sides of the house remained high, for the most part, until near the middle of the century. All this shows that the early glasshouse was modeled after the dwelling or other buildings, and that it had not developed into a structure in which plants were grown for commercial purposes.

The modern commercial forcing-house, with direct roof, low sides, and heated by steam or hot water in closed circuits, is mostly a development of the last forty years. Its forerunner was the propagating-pit of the nurseryman. If anything is lost in sunlight by adopting a simple roof, the loss is more than compensated by the lighter framework and larger glass. In the forcing-house, all architectural ambition is sacrificed to the one desire to create a commercial garden in the frosty months.

Lettuce, cucumbers, tomatoes, carnations, violets, and various other plants are now grown as crops under glass roofs, whereas a generation ago they were usually not forced at all for market or were grown mostly under frames. With the simplifying and cheapening of the glasshouse, amateur flower- and vegetable-growing has acquired a new impetus, and the business of the retail florist has grown amazingly.

Some idea of the increase of the demand for plants may be obtained from the sale of flower-pots. A. H. Hews, of Cambridge, Mass., whose ancestors began the manufacture of pots before 1765, once reported that for a period of twenty-two years, from 1788 to 1810 the accounts of the sales of pots "cover about as many pages as we now often use in one day; and the amount in dollars and cents does not compare with single sales of the year 1894." He also compared the sales for 1869 and 1894 and "found the increase as ten to one; or, in round numbers, 700,000 flower-pots in the former year and 7,000,000 in the latter; and if the same factory can in 1920, twenty-five years later, produce and sell 70,000,000, we shall verily be living in a land of flowers."



1865. First greenhouse in Chicago (1835 or 1836).

One of the earliest greenhouse builders was Frederic A. Lord, who built his first houses, according to Taft, in Buffalo in 1855, and who, in 1872, entered into partnership with W. A. Burnham, at Irvington, on the Hudson. Several firms now make greenhouse building and heating a specialty. In very recent years a new impetus has been given to glasshouse building and work by the establishment of the agricultural experiment stations and the extension of horticultural teaching in the colleges.

The growing literature.

An important feature of American horticulture is its living literature. Persons may care nothing for books; yet the literature of any subject is the measure of its ideals. Persons may say that the books are theoretical and beyond them; yet good books are always beyond, else they are not good. There is no reason for literature if it does not inspire and point to better things. We measure the aspirations of any time by its writings. Whether the fact be recognized or not, the literature of our horticulture is an underlying force which slowly dominates the thoughts and ideals of men. A book is a powerful teacher. It states its propositions, and is silent; and in the silence its lessons sink into the mind.

1866. Interior of a modern commercial greenhouse.—Carnations.

Very many books have enriched American horticulture. Many of them have been poor, but even these may have challenged controversy and have done good. The early books were largely empirical and dogmatic. Downing, for example, in 1845, says that tillage makes better orchards, and he cites cases; but he does not give reasons. He does not mention nitrogen, potash, soil moisture, chemical activities. He does not even mention plant-food in connection with tillage. The horizon has widened since then. Men do not take up things actively until they know the reasons. The poor farmer, not knowing reasons for anything, has no inspiration and goes fishing. Forty years ago, Colonel Waring was the apostle of deep-plowing; yet one should plow neither deep nor shallow until he knows why. Our literature has been singularly devoid of principles and analysis. The great writer is he who catches the significant movements and ideas of his time and portrays them to inspire his reader. Henderson first caught the rising commercial spirit of our vegetable-gardening; his "Gardening for Profit" was the greatest American vegetable-gardening book, even if now out of date as a book of practice. American pomology has several strong names amongst its writers. Most of these writers have sacrificed fundamental considerations to varieties. The first sustained effort to write on fruit-growing from the point of view of underlying principles was by Charles R. Baker, who in 1866 published his "Practical and Scientific Fruit Culture." But the time was apparently not yet ready for a solid book of this kind, and much of the discussion lacked vital connection with the orchard. The book was suggestive of the study and the compiler. Coxe, Kenrick, Manning, Downing, Thomas, Warder, Barry, Fuller, are significant names in American pomological literature. In floriculture there have been many excellent treatises, but there is not yet a single great or comprehensive book. In recent years, the making of technical horticultural literature is passing more and more from the working horticulturist to the specially trained student and writer, particularly to those who are connected with colleges of agriculture and experiment stations. At the same time, the amateur and strictly popular writings are increasing rapidly, and the modern publisher has made many of the books very attractive in their mechanical execution.

The periodical literature is not to be overlooked, although we do not now have in America horticultural magazines and journals comparable with those of Europe. These serial writings, however, are voluminous and important, and must be taken into account when any complete estimate is made of American horticultural literature. On the writing of "gardening literature," Henry Ward Beecher wrote nearly fifty years ago: "We, in America especially, need men to write who devote time, thought and knowledge to this elegant department of knowledge as they do to the sciences of law, of medicine, or theology; and, although we are glad of transient and cursory writing, rather than none, I feel the want, in American horticultural magazines, of writing that is the result of long and close observation, and of ripe reflection." L. H. B.

HORTICULTURE, LITERATURE OF. The written record of American horticulture has not yet been carefully studied, although the collecting of books has lately assumed much interest and importance. There are no full lists of these writings; and it is to make a preliminary contribution to such lists that the present compilation is presented. The written word persists long after the word of mouth has been lost; and it admits of no doubt as to dates and statements of fact. It is essential that any people arrive at an appreciation of its records in a given subject, that it may have perspective and develop sound judgments.

In the preceding pages something has been said about the development of writing on horticulture in North America. The early general writings are discussed beginning on page 1509. The fruit-growing literature is reviewed from page 1513. The periodical literature occupies considerable space, beginning page 1559. The reports of horticultural societies are recorded from page 1553. In the present discussion, the regularly printed horticultural books are listed in detail, from the first book on horticulture in North America, so far as it may be known, to the current date. In the preceding accounts, some of the early writings on general agriculture are discussed, as bearing on the history; many other early writers might have been mentioned, if the subject had taken a wider field, as Binns (Frederick, Maryland, 1803), Spurrier (Worcester, 1792), Parkinson (Philadelphia, 1799), George Logan (Philadelphia, 1797), Du Pre ("Culture of Cotton," 1799, perhaps the book mentioned on page 1510), and others.

North American horticultural books.

In the introduction to the "History of the Massachusetts Horticultural Society" (1880) it is said that Mrs. Martha Logan, in South Carolina, "when seventy years old, wrote a treatise on gardening called the 'Gardener's Kalendar,' which was published after her death in 1779, and as late as 1808 regulated the practice of gardening in and near Charleston. She was a great florist, and uncommonly fond of a garden" (page 1510). In the Charleston library there is no separate book of this kind, but the "Gardener's Calendar by Mrs. Logan" appears in succeeding issues of the "Carolina and Georgia Almanac," comprising six pages. The earliest date there available is in the Almanac for 1798. It has been spoken of as a pamphlet, and it may have been reprinted separately. The first almanac printed in South Carolina was Tobler's for 1752. This almanac contains a "Gardner's Kalender, done by a Lady of this Province and esteemed a very good one." Perhaps this work was by Mrs. Logan. There does not appear to be any book by Mrs. Logan in the antiquarian libraries or lists, although, following Allibone, Evans apparently erroneously included it in Vol. IV of his "American Biblography" as of the date of 1772. Mrs. St. Julien Ravenel, in "Charleston, the Place and the People" (1906), writes that "Mrs. Logan was the daughter of the gallant Colonel Daniel. Her 'Gardeners' Chronicle,' written when over seventy, was in great demand formerly, but seems to have utterly perished, the most careful search failing to produce a copy."

The almanacs were important mediums of information in the early days, and it is probable that some of the first instruction in horticulture was given in them. In "Poor Will's Almanack" for 1787, printed in Philadelphia in 1786, there is a "Gardener's Kalender; or useful memorandums of work necessary to be done, monthly, in the gardens and orchards of the Middle States," according to Evans. The "Southern States Ephemeris" for 1788, printed in Charleston in 1787, contains "a new and copious gardener's calendar" for the southern states. In Isaac Brigg's "Georgia and South Carolina Almanac" for 1800, printed in Augusta in 1799, there is a calendar, according to Evans, by Robert Squibb. The agricultural matter in the New England almanacs is well known.

In 1796, there was printed at Newburyport, Massachusetts, by Blunt and March, for John Dabney, Salem, "An Address to Farmers" on a number of interesting subjects. It contains a part or chapter on the character of a complete farmer; one on the profits of a nursery; another on the advantages of an orchard. There are references in the appendix to apples, barley, cabbages, carrots, clover, and other subjects. The parts were "extracted principally from a variety of authors."

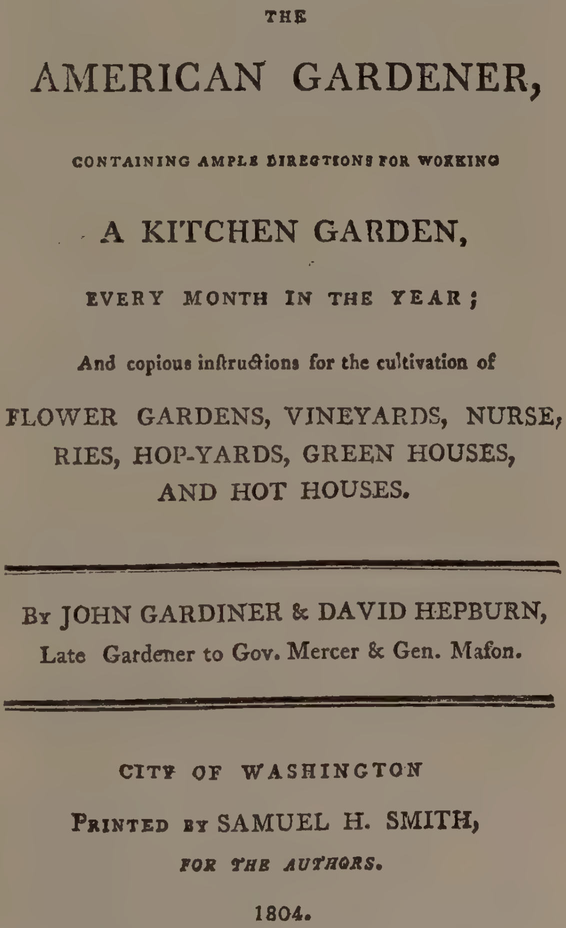
Apparently the earliest separate book on a horticultural subject published in North America (if the Logan is not counted), was Robert Squibb's "The Gardener's Kalender for South Carolina and North Carolina," published in Charleston in 1787, and again in 1809, 1827, and 1842 (Fig. 1864). The second work appears to be an American edition of Marshall's "Introduction to the Knowledge and Practice of Gardening," Boston, 1799. The second indigenous horticultural book, apparently, appeared in 1804, "The American Gardener," by John Gardiner and David Hepburn (Fig. 1867). It was published at Washington. This book had an extensive sale. It was revised by "a citizen of Virginia," and republished in Georgetown, D.C., in 1818 (see Hepburn, p. 1579). A third edition appeared in 1826.

This book was followed in 1806 by Bernard M'Mahon's excellent and voluminous "American Gardener's Calendar," in Philadelphia. This work enjoyed much popularity, and the eleventh edition appeared as late as 1857. For fifty years it remained the best American work on general gardening. M'Mahon, remembered in the Mahonia barberries, was an important personage. He was largely responsible for the introduction into cultivation of the plants collected by Lewis and Clark. These early books were calendars, giving advice for the successive months. They were made on the plan then popular in England, a plan which has such noteworthy precedent as the excellent "Kalendarium Hortense" of John Evelyn, which first appeared in 1664, and went to nine regular editions. Other early books of this type were "An old gardener's 'Practical American Gardener,'" Baltimore, 1819 and 1822; Thorburn's "Gentleman's and Gardener's Kalendar," New York, the third edition of which appeared in 1821.

As throwing some light on the processes of book-making in those days, the following announcement by Squibb in the "Charleston Evening Gazette," July 4, 1786, will be interesting:

> To the Public.
>
> From the frequent solicitations of a number of Gentlemen of this and adjoining states, the subscriber has been induced to undertake a work, entitled, "The South Carolina, Georgia, and North Carolina Gardeners Calendar," which, from its general utility, he flatters himself, will meet the approbation of the Public at large. The English publications hitherto made use of to point out and direct the best methods of Gardening by no means answer the purpose, as they tend to mislead instead of instruct, and suit only the European parts for which they were designed.—This work is deduced from practice and experience in this climate, wherein the most certain and simple methods are clearly pointed out, so as to render the art of Gardening easy and familiar to every capacity.
>
> The work will be comprised in an octavo volume of about 200 pages, which will contain ample directions for whatever is necessary to be done in the Kitchen and Fruit Garden for every month in the year.
>
> Terms of subscribing One Dollar; half on subscribing, the remainder on the delivery of the book, which will be printed with all possible dispatch. Robert Squibb Nursery and Seedsman.
>
> Subscriptions will be received at the subscriber's Garden, the upper end of Tradd street, at the Printers of this Paper, at Bower & Markland's Printing-office, Church street, and at the principal Taverns.

The first indigenous book written on the topical plan, treating subject by subject, is apparently Coxe's fruit book, 1817; the second appears to have been Cobbett's "American Gardener," published at New York in 1819,



THE
AMERICAN GARDENER,
CONTAINING AMPLE DIRECTIONS FOR WORKING
A KITCHEN GARDEN,
EVERY MONTH IN THE YEAR;
And copious inſtructions for the cultivation of
FLOWER GARDENS, VINEYARDS, NURSERIES,
HOP-YARDS, GREEN HOUSES,
AND HOT HOUSES.

By JOHN GARDINER & DAVID HEPBURN,
Late Gardener to Gov. Mercer & Gen. Maſon.

CITY OF WASHINGTON
PRINTED BY SAMUEL H. SMITH,
FOR THE AUTHORS.
1804.

1867. Title-page, exact size, of what is supposed to be the second or third indigenous American horticultural book.

in London in 1821, and which passed through subsequent editions. This William Cobbett is the one who edited the federalist paper in Philadelphia known as "Peter Porcupine's Gazette," and whose attack upon Dr. Rush's treatment of yellow fever brought against him a judgment for damages, and which decided him to return to England in 1800, whence he had come, by way of France, in 1792. In London he again took up political writing, and in 1817 he retreated to America to escape political penalties, and resided upon a farm on Long Island until 1819. He kept a seed store in New York in 1818, and we find Grant Thorburn disputing with him in the "Evening Post" as to which sold the better rutabaga seed at one dollar a pound. Cobbett, it seems, claimed to have been the introducer of this vegetable, also known as the Russian turnip, into this country; but Thorburn retorts that "in the year 1796 a large field of these turnips was raised by Wm. Prout on that piece of ground now occupied by the navy yard, at the city of Washington." He completed his life in England, becoming a voluminous author upon political and economical subjects. It is interesting to note, in connection with this dispute about the turnips, that the kohlrabi was introduced about the same time, and Deane says of it in 1797, that "whether this plant, which has but newly found its way into our country, is hardy enough to bear the frost of our winters, I suppose is yet to be proved." It was recommended to be grown as a biennial, which accounts for Deane's fear that it might not pass the winters.

Fessenden's "New American Gardener," made upon the topical plan, appeared in Boston in 1828, and went to various editions; and from this time on, gardening books were frequent. Some of the leading early authors are Thomas Bridgeman, of New York; Robert Buist, of Philadelphia, and Joseph Breck, of Boston.

The first American book devoted wholly to flowers was probably Roland Green's "Treatise on the Cultivation of Flowers," Boston, 1828 (p. 1511). Edward Sayers published the "American Flower Garden Companion," in Boston, in 1838. From 1830 to 1860 there appeared many of those superficial and fashionable books which deal with the language of flowers, and which assume that the proper way to popularize botany is by means of manufactured sentiment.

The first book devoted to a special flower was probably Sayers' treatise on the dahlia, Boston, 1839, which appeared only a year later than Paxton's well-known book in England. Sayers' book also included the cactus. The next special flower-book seems to have been Buist's "Rose Manual," Philadelphia, 1844, although a sentimental book on the "Queen of Flowers" had appeared in the same city in 1841. Buist's book went to at least four editions. It was followed by Prince's in 1846, and by S. B. Parson's "The Rose: Its History, Poetry, Culture and Classification," 1846. Parson's book went to a revised edition. Of later-date flower-books there are several of importance, but it is not the purpose of this paragraph to trace more than the beginnings of American floricultural writings.

In 1838 appeared a book in French in New Orleans. This was Lelievre's "Nouveau Jardinier de la Louisiane." It was a small book of 200 pages, with a calendar and brief directions for the growing of vegetables, fruits and flowers. Singularly enough, a French book also appeared at the other extreme of the country. This was Provancher's "Le Verger-Canadien," published in Quebec in 1872.

It is in the pomological writings that North America has made the greatest contributions to horticultural literature. William Forsyth's excellent "Treatise on the Culture and Management of Fruit Trees" appeared in London in 1802, and it was widely read, "an impression of 1,500 copies (of the first edition) in 4to having been sold in a little more than eight months." An American edition, by William Cobbett, appeared in New York and Philadelphia in 1802, and in Albany in 1803, and an epitome of it by "an American farmer," was published in Philadelphia in 1803. The first American pomological book was William Coxe's "View of the Cultivation of Fruit Trees," published in Philadelphia in 1817, a work known to students of horticultural literature for the uniform completeness and accuracy of its descriptions. A feature of this excellent work are the many woodcuts of varieties of fruits. Although not answering the requirements of the present day, they were considered to be very good for the time and for a new country. One of them is reproduced in Fig. 1858 to show the style of workmanship. Coxe had 100 woodcuts of apples, 63 of pears, 15 of peaches, 17 of plums, 3 of apricots, 2 of nectarines. This makes 200 engravings, which would be considered liberal illustration even at the present day.

James Thacher's "American Orchardist" appeared in Boston in 1822, and the second edition at Plymouth in 1825. The first edition was also bound with William Cobbett's "Cottage Economy," and the double volume was issued in New York in 1824 as "American Orchardist and Cottage Economy." "The Pomological Manual," New York, 1831 (second edition 1832), is a compilation of descriptions of varieties, by William Robert Prince and William Prince, son and father respectively. William Kendrick's "New American Orchardist" was published in Boston in 1833. The eighth edition appeared in 1848. Like all early works, it devotes most of its space to varieties. Robert Manning published his admirable "Book of Fruits," at Salem, in 1838, being aided by John M. Ives. Upon the death of Manning, Ives published a second edition in 1844 under the title of "The New England Fruit Book," and a third in 1847 as "The New England Book of Fruits." Downing's "Fruits and Fruit Trees of America" appeared in 1845 in two forms, duodecimo and octavo, although both issues were printed from the same type. One issue of the octavo form contained colored plates. Thomas' "Fruit Culturist," which is known in subsequent editions as "The American Fruit Culturist," appeared in 1846. Other pomological writings which appeared before 1850 are Sayers' "American Fruit Garden Companion," Boston, 1839; Hoffy's "Orchardist's Companion," Philadelphia, 1841; Bridgeman's "Fruit Cultivator's Manual," New York, 1845; Floy's American edition of George Lindley's "Guide to the Orchard and Fruit Garden," New York, 1846; Jaque's "Practical Treatise on the Management of Fruit Trees," Worcester, 1849; Goodrich's "Northern Fruit Culturist," Burlington, Vt., 1849; Cole's "American Fruit Book," and others. Barry's "Fruit Garden" appeared in 1851.

Of these pomological books, the first place should be given to those of Coxe, Kendrick, Manning, Downing, Thomas and Barry. The influence of Downing's "Fruits and Fruit Trees of America" probably has been greater than that of all others in extending a love of fruits and a critical attitude toward varieties. Begun by Andrew Jackson Downing—perhaps the fairest name in American horticultural literature—it was continued and revised by the elder brother, Charles, after the untimely death of the former. Most of these works were largely compilations. A notable exception was Manning's "Book of Fruits." In the introductory remarks to this volume is the following statement: "There is one circumstance to which we venture to call the attention of our readers—that while some recent works on pomology are compiled from earlier authors, or from information derived at second-hand, the writers themselves seldom having the means of observation in their power, we have in these pages described no specimen which we have not actually identified beyond a reasonable doubt of its genuineness." It was Manning who chiefly made known to Americans the pears of the Belgian, Van Mons. He was one of the most careful observers amongst American pomologists.

The awakening pomology of the region west of the Alleghanies found expression in Elliott's "Fruit Book," 1854, whose author wrote from Cleveland, and which went to a new edition in 1859 as "The Western Fruit Book," with the preface dated at St. Louis; and Hooper's "Western Fruit Book," 1857, written at Cincinnati. John A. Warder was a guiding spirit of the opening West.

The earliest separate grape book was published in Washington in 1823, by the prophetic Adlum, "A Memoir on the Cultivation of the Vine in America." This went to a second edition in 1828. Before this time (1806), S. W. Johnson had devoted much space to the grape in his "Rural Economy," published at New Brunswick, N. J., and he published interesting pictures of grape-training (Fig. 1859). Adlum's book was followed in 1826 by the "American Vine Dresser's Guide," by Dufour. This important work also gave pictures of grape-training, one of which is reproduced in Fig. 1860. The larger number of the grape books appeared before the close of the Civil War, although the larger part of the development of the subject has taken place since that time.

LIST OF AMERICAN HORTICULTURAL BOOKS

The purpose of the following list is to record all the regular publishers' or book-trade books, and their editions, on fruit-growing, flower-growing, vegetable-gardening, and closely related subjects, that have been published in the United States and Canada to the close of the year 1914. It does not include British or other imported books that apparently are printed abroad and then bound up in this country with a new title-page, or even those of foreign authorship that are merely reprinted in this country, for the reason that they do not represent American experience and are really not American works. Neither does the list contain all excerpts or separates of articles or addresses that may be put in pamphlet form, nor the reports and publications of government departments. Revisions and modified editions, as indicated by new copyright or changed title-page, are included, but not new impressions or re-issues.

The entries comprise the name of the author (or editor) as given on the title-page, the exact title, the phraseology of the subtitles, whether illustrated, place of publication, date (n. d. means that no date is given on the title-page), date of copyright (n. c. means that there is no copyright imprint), publisher, number of pages (roman numerals are those of prefatory pages), and size of the bound volume to one-quarter of an inch. It is intended that the capitalization and punctuation of the original shall be followed, but as the list has been compiled from several sources it has been impossible to be consistent in these details. The name of the author is intended to be given in the form in which it appears in the given book, on the assumption that the author's wishes and usage are to be respected.

Every pains has been taken to make this list accurate and complete. It was first put in type more than two years ago, and it has been gone over by many persons. Revised proofs have been taken and these have again been gone over. Special aid has been given by the Library of the United States Department of Agriculture, Library of Congress, and the Massachusetts Horticultural Society.

Abbott, Francis B. Hand-Book of Small Fruits. Illus. Chicago, Ill. n. d. Paper 5¾ x 3½. [1889?]

Adams, H. S. Flower Gardening. Illus. New York. 1913. [c. 1913.] McBride, Nast & Co. 253 pp. 5 x 7½.

———. Lilies. Being one of a series of flower monographs. Illus. New York, 1913. [c. 1913.] McBride, Nast & Co. 116 pp. 5 x 7.

———. Making a Rock Garden. Illus. New York. 1912. [c. 1912.] McBride, Nast & Co. 52 pp. 6½ x 4¼. (House and Garden Making Books.)

———. The same. New York. 1857. [c. 1847.] C. M. Saxton & Co.

———. The same. A new and improved edition. New York. 1860. [c. 1847.] C. M. Saxton, Barker & Co. xii + 164 pp.

———. The same. 1864.

———. Kitchen-Gardening; containing complete practical directions for the planting and cultivation of all kinds of vegetables. Illus. Philadelphia. n. d. Henry T. Coates & Co. 152 pp. 7¾ x 5¼.

———. The Young Gardener's Assistant; containing a catalogue of garden and flower seeds, with practical directions under each head for the cultivation of culinary vegetables, some of which are not generally introduced into the United States. Brooklyn. 1829. [c. 1829.] Printed by Nichol & Mathews. 96 pp. 7 x 4.

———. The same. 3d ed., with an appendix; containing directions for cultivating fruit trees and the grape vine. New York. 1832. [c. 1832.] Printed by Geo. Robertson. vi + 272 pp. 7 x 4½.

———. The same. The Young Gardener's Assistant; containing a catalogue of garden and flower seeds, with practical directions under each head, for the cultivation of culinary vegetables and flowers; also, directions for cultivating fruit trees, the grape vines, etc.; to which is added a calendar, showing the work necessary to be done in the various departments of gardening in every month of the year. 7th ed., improved. New York. 1837. [c. 1837.] Mitchell & Turner. vi + 360 pp. 8¼ x 5.

———The same. 8th ed., improved. 1840. [c. 1840.] vi + 408 pp. 8¼ x 5¼.

———. The same. 10th ed., improved. In three parts. New York. 1844. For sale by the author. (Each part paged separately). 9 in.

———. The same. 12th ed., with an appendix. In three parts, containing catalogues of garden and flower seed, with practical directions under each head for the cultivation of culinary vegetables and flowers; also, directions for cultivating fruit trees, the grape vine, etc. To which is added a calendar to each part, showing the work necessary to be done in the various departments each month in the year. The whole adapted to the climate of the United States. 1847. [c. 1847.] (Each part paged separately.)

———. The same. The whole adapted to the climate of the United States. New edition, with an appendix, containing remarks on the alleged disease of the potato, etc. Part I. Vegetable department. New York. 1865. [c. 1847.] William Wood & Co. 7½ x 5. (The three parts were also published separately as "Kitchen Gardener's Instructor," "Fruit-Cultivator's Manual," and "Florist's Guide.")

Bright, William. Bright's Single Stem, Dwarf and Renewal System of Grape Culture; adapted to the vineyard, the grapery, and the fruiting of vines in pots, on trellises, arbors, etc. New York. 1860. [c. 1860.] C. M. Saxton, Barker & Co. 123 pp.

———. The same. 2d ed. New York. 1861. [c. 1860.] C. M Saxton, Barker & Co. 155 pp.

Brill, Francis. Cauliflowers and How To Grow Them; with plain, practical and explicit directions in minute detail for the cultivation and management of this crop, from the sowing of the seed to the marketing of the product. Riverhead, N. Y. 1886. [n. c.] Published by the author. 16 pp. 9 x 5¾.

———. Farm-Gardening and Seed-Growing. New and enlarged edition. With suggestions to seed-growers. By George Thurber. New York. 1884. [c. 1883.] Orange Judd Company. 166 pp. 7½ x 5.

———. The same. 1886.

———. The same. New York. n. d. [c. 1872.] Orange Judd Company. 157 pp.

Brincklé, William D., Editor. Hoffy's North American Pomologist; containing numerous finely colored drawings, accompanied by letter press descriptions, etc., of fruits of American origin. Portrait. Book No. 1. Philadelphia, 1860. [c. 1860.] Prepared and published by A. Hoffy. vi + 44 pp. 10¾ x 8.

Brooks, Sarah Warner. A Garden with House Attached. Illus. Boston. 1904. R. G. Badger. 118 pp. 9¼ in.

———. The same. 1911. [c. 1911.]

Brown, Glenn, Editor. European and Japanese Gardens. Papers read before the American Institute of Architects: Italian Gardens, by A. D. F. Hamlin. English Gardens, by R. Clipston Sturgis. French Gardens, by John Galen Howard. Japanese Gardens, by K. Honda. Edited for the American Institute of Architects by Glenn Brown, Secretary. Illus. Philadelphia. 1902. [c. 1902.] Henry T. Coates & Co. 9¾ x 7.

Brown, James B. Reference book explanatory of Brown's improved above-ground storehouse, for the keeping over winter of fruit, sweet and Irish potatoes, etc., together with a prize essay on the propagation, cultivation, and preservation of the sweet potato. M'Minnville, Tenn. 1886. Standard Printing House. 20 pp. 9 in.

Brown, Waldo F. Gardener's Pocket Manual. A short, practical treatise on gardening. Illus. Springfield, O. [c. 1878.] T. H. Edwards & Co. 105 pp. 6 in.

Bryant, W. C See Field, F. E. The Greenhouse as a Winter Garden; see Turner, Mrs. Cordelia Harris. The Floral Kingdom.

Buchanan, Robert. The Culture of the Grape, and Wine Making; with an appendix containing directions for the cultivation of the strawberry, by N. Longworth. Illus. Cincinnati. 1852. [c. 1852.] Moore & Anderson. 142 pp.

———. The same. Illus. 2d ed. Cincinnati. 1852. [c. 1852.] Moore & Anderson. 142 pp.

———. The same. Illus. 3d ed. Cincinnati. 1852. [c. 1852.] Moore & Anderson. 142 pp.

———. The same. Illus. 4th ed. Cincinnati. 1853. [c. 1852.] Moore, Anderson & Co. 142 pp.

———. The same. Illus. 5th ed. Cincinnati. 1855. [c. 1852.] Moore, Wilstach, Keys & Co. 142 pp.

———. The same. Illus. 6th ed. Cincinnati. 1860. [c. 1852.] Moore, Wilstach, Keys & Co. 142 pp.

———. The same. Illus. 7th ed. Cincinnati. 1861. [c. 1852.] Moore, Wilstach, Keys & Co. 142 pp.

———. The same. Illus. 8th ed. Philadelphia. n. d. Crawford & Co. 142 pp.

———. The same. 8th ed. Cincinnati. 1865. Moore, Wilstach & Baldwin. 142 pp. 8 in.

Buchanan, W. D. See Tritschler, C. H. A Practical Treatise on How to Grow Flowers.

Budd, J. L. A Horticultural Handbook. Illus. Des Moines, Iowa. March, 1900. Wallace Publishing Company. 160 pp. 6 x 4½

——— and Hansen, N. E. American Horticultural Manual. Part I. Comprising the leading principles and practices connected with the propagation, culture, and improvement of fruits, nuts, ornamental trees, shrubs, and plants in the United States and Canada. Illustrated with over one hundred figures and explanatory designs. New York. 1902. [c. 1902.] John Wiley & Sons. xx + 417 pp. 7½ x 5.

———. The same. Part II. Systematic Pomology; containing descriptions of the leading varieties of the orchard fruits, grapes, small fruits, subtropical fruits, and the nuts of the United States and Canada. Illustrated by hundreds of outlines of the leading commercial fruits and nuts. 1903. vi + 491 pp.

Buell, J. S. The Cider Makers' Manual. A practical handbook, which embodies treatises on the apple; construction of cider mills, cider-presses, seed-washers, and cider mill machinery in general; cider making; fermentation; improved processes in refining cider, and its conversion into wine and champagne; vinegar manipulation by the slow and quick processes; imitation ciders; various kinds of surrogate wines; summer beverages; fancy vinegars, etc. Illus. Buffalo. 1869. [c. 1869.] Published by Haas & Kelley. viii + 174 pp. 7½ x 5.

———. The same. Revised edition, with alterations. Buffalo, 1874. [c. 1869.] Haas, Nauert & Co. 183 pp. 7½ x 5.

Buist, Robert. American Flower-Garden Directory; containing practical directions for the culture of plants, in the flower-garden, hot-house, green-house, rooms or parlor windows, for every month in the year; with a description of the plants most desirable in each, the nature of the soil and situation best adapted to their growth, the proper season for transplanting, etc.; with instructions for erecting a hot-house, green-house, and laying out a flower-garden; also, Table of Soils most congenial to the plants contained in the work—the whole adapted to either large or small garden; with instructions for preparing the soil, propagating, planting, pruning, training, and fruiting the grape-vine, with descriptions of the best sorts for cultivating in the open air. 2d ed., with numerous additions. Philadelphia. 1839. [c. 1839.] E. L. Carey and A. Hart. viii + 379 pp. 9 x 5¾.

———. The same. 3d ed., with numerous additions. Philadelphia. 1845. [c. 1845.] Carey & Hart. xi + 345 pp. 7¾ x 4¾.

———. The same. 4th ed., with numerous additions. Philadelphia. 1851. A. Hart (late Carey & Hart). xvi + 339 pp.

———. The same. 5th ed., with numerous additions. Philadelphia. 1852. [c. 1851.] A. Hart (late Carey & Hart). xvi + 339 pp. 8 x 5.

———. The same. 6th ed., with numerous additions. 1854. [c. 1854.] xvi + 342 pp. 7½ x 5.

———. The same. 6th ed., New York. 1859. A. O. Moore.

———. The same. New edition, with numerous additions. New York. n. d. [c. 1854.] Orange Judd Company. xvi + 342 pp. 7¾ x 5.

———. For 1st ed. see Hibbert. The American Flower Garden Directory.

———. The Family Kitchen Gardener; containing plain and accurate descriptions of all the different species and varieties of culinary vegetables; with their botanical, English, French, and German names, alphabetically arranged, and the best mode of cultivating them in the garden or under glass; with a description of implements and medicinal herbs in general use. Also, descriptions and characters of the most select fruits, their management, propagation, etc. Illustrated with twenty-five engravings. New York. 1852. [c. 1847.] C. M. Saxton. 216 pp. 7¾ x 5.

———. The same. New York. 1867. [c. 1847.] Orange Judd Company. 216 pp. 7¾ x 5.

———. The Rose Manual; containing accurate descriptions of all the finest varieties of roses, properly classed in their respective families, their character and mode of culture, with directions for their propagation, and the destruction of insects. With engravings. Philadelphia. 1844. [c. 1844.] For the author and Messrs. Carey & Hart. xii + 182 pp. 7½ x 5.

———. The same. 2d ed., with additions. 1847. [c. 1844.] xii + 192 pp. 7½ x 5.

———. The same. 3d ed., with additions. 1851. Published by the author. xii + 188 pp. 7¼ in.

———. The same. 4th ed., with additions. 1854. [c. 1844.] For the author, A. Hart, and Lippincott, Grambo, & Co. xvi + 196 pp. 7¾ x 4¾.

Bulos. See Fisher, S. I. Observations on the Character and the Culture of the European Vine.

Subject index to the foregoing lists.

To aid the consultant to find the books on special subjects in the preceding bibliography, the following classified list is appended. It is impossible so to classify the titles as to organize them into definite and distinct groups, but the index may nevertheless afford the reader some relief. Many of the books cover a great variety of subjects; these are mostly placed under "General gardening and horticulture." Many of the titles are of such a nature that they cannot be entered in the index, as here constituted. The index designates only the books wholly or chiefly devoted to the given subject, and does not refer to chapters or parts in the miscellaneous or general books.

Evergreens and hedges.—Butterfield; Harrison; Hoopes; Main; Powell, E. P.; Warder.

Flowers and flower-gardening.—Adams; Allen, J. F.; Arnold; Barnard; Bennett; Blanchan; Bourne; Breck; Bridgeman; Buist; Casey; Clark; Cobbett; Complete Florist; Crawford; Darlington; Darrow; Dearborn; Doyle; Eley; Elliott, W. R.; Ely; Flower Garden; Frothingham; Green, R.; Halliday; Halsham; Harrison; Hassard; Hatfield; Henderson; Hibbert; Hooper, L.; How to Grow Asters; How to Make a Flower Garden; Hunt; Jenkins, E. N.; Johnson, L.; Johnson, S. O.; Keeler; Kirby; Long; Long Bros.; Loudon; McGregor; Maeterlinck; Mathews; Morton; Newman, J. B.; Page; Peacock; Practical Florist; Rand, E. S.; Rexford; Rion, H.; Rion, M. C.; Ruston; Sayers; Saylor; Scott, W.; Shelton; Smiley; Smith, E. E.; Solly; Tabor; Tuberous Begonias; Turner, C. H.; Vick; Washburn & Co.; Weed, C. M.; Wellcome; Winter; Woods.

Bulbs, special books: Allen, C. L.; Dreer; Fuld; Henderson; Rand, E. S.; Rexford; Tabor.

Carnation, special books: Lamborn; Ward.

Chrysanthemum, special books: Barker; Herrington; Mathews; Morton; Powell, I. L.; Smith, E. D.

Lily, special books: Adams; Boardman; Childs.

Orchids, special books: Boardman; Burberry; Hansen; Miner; Rand, E. S.

Rose, special books: American Rose Culturist; Buist; Drennan; Ellwanger, H. B.; Good; Hatton; Hole; Holmes, E.; Jenkins, T. B.; Parkman; Parsons, S. B.; Prince, W. R.; Roses and How to Grow Them; Saylor; Shaw, H.; Thomas, G. C.; Wellcome.

Sweet pea, special books: Dick; Hutchins; Kerr; Sunset Seed and Plant Company; Zvolanek.

Violet, special books: Galloway; Saltford.

Fruits and fruit-growing.—Alwood; Aspinwall, J.; Bailey; Baker, C. R.; Barry; Bates; Bealby; Bell; Biggle; Brehaut; Bridgeman; Brinckle; Budd; Cellon; Chase; Cobbett; Cole; Collingwood; Complete Kitchen and Fruit Gardener; Coxe; Creighton; Culver; Downing, A. J.; Downing, C.; Dwyer; Dygert; Elliott, F. R.; Elliott, W. R.; Favor; Fletcher, S. W.; Forsyth; Galusha; Gilbert; Goff; Goodrich; Gray; Green, C. A.; Green, S. B.; Greening; Gregg; Gurney; Haines; Hansen, N. E.; Harcourt; Hedrick; Hendrick; Herrick; Hooper, E. J.; Hovey; Hurst; Jaques; Kenrick; Kiely; Kitchen and Fruit Gardener; Knowlton, D. H.; Lacy; Larsen; Lawson; Lelong; Leopold; Lindley; McNeil; Manning, R.; Maynard; Merchant; Moore, S. W.; Morris; Moulson; Narrigan; Pabor; Paddock; Parker; Phelan; Phillips; Poole; Powell, E. C.; Powell, E. P.; Prince, W. R.; Rivers; Rockwell; Sayers; Sears; Smith, J.; Stark; Stedman; Stringfellow; Strong; Teague; Thacher; Thomas, J. J.; Thornton; Turner, W.; Warder; Waring; Waugh; Wickson; Wilder, G. P.; Young.

Apples, special books: Bailey; Beach; Buell; Burritt; Cline; Fitz; Green, C. A.; Lawrence; Powell, G. T.; Todd; Waugh; Whitten; Woolverton; Young Men's Christian Association.

Date, special book: Popenoe.

Fig, special books: Eisen; Roeding; Van Velzer; Worthington.

Grape, special books: Adlum; Allen, J. F.; Andrae; Bailey; Barclay; Becker; Berneaud; Bright; Buchanan; Busby; Bush; Chapman; Chazotte; Chorlton; De Caradeuc; De Courtenay; Denniston; Du Breuil; Dufour; Eakin; Eisen; Emerson, E. R.; Engelmann; Fisher; Flagg; Fuller; Grant; Green, C. A.; Hamm; Haraszthy; Haskell; Hedrick; Heyne; Hoare; Hofer; Hoops; Husmann; Hyatt; Kecht; Keech; Knowlton, J. M.; Longworth; Loubat; McCollom; McMullen; McMurtrie; Mead; Millard; Mitzky; Mohr; Muench; Munson; My Vineyard at Lakeview; Nessler; Osborn; Persoz; Phelps; Phin; Preyer; Prince, W. R.; Rafinesque; Reemelin; Aiehl; Rixford; Rubens; Saunders; Sayers; Spooner; Strong; Tomes; Treatise on Cultivation of Grapes; Tryon; Van Buren; Viala; Wait; Warder; Williams, E.; Woodward, G. E.

Nuts, special books: Allen, W. F.; Dygert; Fuller; Hume; Lelong; Parry, J. R.; Price, E. M.; Risien; Roper; Stewart, H. L.; Wight.

Olive, special books: Bleasdale; Calkins; Chazotte; Cooper; Flamant; King; Lelong; Marvin; Pohndorff.

Oranges, lemons, and other citrous fruits, special books: Canada; Davis, G. W.; Fish; Fowler, J. H.; Gallesio; Garcelon; Garey; Hume; Lelong; Manville; Moore, T. W.; Prange; Spalding.

Peach, special books: Black; Fitz; Fletcher, R. R.; Fulton; Harker; Reinert; Rutter; Waugh; Wilcox.

Pear, special books: Berckmans; Black; Field, T. W.; Green, C. A.; Illustrated Pear Culturist; A New Treatise . . . . the pear tree; Parry, W.; Quinn; Thompson, W. W.

Plum and **prune,** special books: Clarke; Cope; Hedrick; Lelong; Waugh.

Quince, special book: Meech.

Small-fruits, special books: Abbott; Aspinwall, B.; Barnard; Bassett; Beede; Biggle; Blacknall; Boulton; Card; Cary; Clemmens; Crawford; Durand; Eastwood; Erwin; Farmer; Fragaria; Fuller; Galusha; Gillet; Green, C. A.; Grosvenor; Hall, D. M.; Hills; How to Grow Strawberries and other Fruits; Knapp; The Lawton or New Rochelle Blackberry; M'Kay; Merrick; Pardee; Parry, W.; Preyer; Purdy; Richards; Roe; Smith, M. O.; Snider; Starr; Strawberry Report; Terry; Trowbridge; Webb; White, J. J.; Whitten; Wilkinson.

General gardening and horticulture.—Adams; Agricola; Albaugh; Albee; Angier; Bailey; Baker, T.; Barnard; Barnes; Batson; Beadle; Beecher; Biggle; Bray; Bridgeman; Brooks; Brown, W. F.; Budd; Busch; Buschbauer; Church; Cleves; Clute; Cobbett; Collingwood; Copeland; Crosier; Davis, L. D.; Duncan; Earle; Edgeworth; Egan; Elder; Elliott, F. R.; Elliott, J. W.; Elwanger, G. H.; Ely; Fessenden; Field, F. E.; Field, H.; Fiske; Flint, E. D.; Flint, L. C.; Fullerton; The Garden; Gardiner; Gipson; Goff; Grundy; Hall, B.; Hall, G. P.; Hargrave; Harris; Harrison; Hawthorne; Hays; Hayward; Heikes; Hemenway; Henderson; Higgins; How to Grow Flowers, Fruit and Vegetables; Howard; Howe; Huber; Hunn; Jack; Jacques; Johnson, C.; Johnson, G. W.; Johnson, M. W.; Johnson & Stokes; Kains; Kirkegaard; Landreth; Laroque; Lelievre; Lindley, J.; Livingston, L. S.; Long; Lounsberry; Lowell; Lyon; MacGerald; McCauley; McLaren; M'Mahon; Marshall; Miller, C. H.; Miller, L. K.; Miller, T. B.; Miller, W.; Munro; Neill; Newman, J. S.; Oliver; Paine; Parsons, H. G.; Peek; Pierce; Powell, G. T.; Practical American Gardener; Prince, W.; Rand, A. C.; Rexford; Rion, H.; Rockwell; Roe; Rogers, J. E.; Rowles; Schenck; Scott, T.; Sedgwick; Seldon; Sewell; Seymour; Shafer; Shaw, E. E.; Shaylor; Sheehan; Shields; Shinn; Simson; Sinclair; Skinner, C.; Skinner, H.; Slade; Squibb; Stebbins; Stewart; Stewart, H.; Stewart, J. T.; Storke; Stringfellow; Tabor; Teat; Ten Acres Enough; Thaxter; Thomas, Mrs. T.; Thorburn; Tritschler; Underwood, L.; Urban; Utter; Verplanck; Warner, A.; Warner, C. D.; Watson; Weed, C. M.; White, W. N.; Whitner; Wilder, M. P.; Willard; Williams, D.; Woodward, R. T.; Woolson; Wright, M. O.; Wright, W. P.; Yates; Year Book of Farm and Garden.

Greenhouses.—Bryant; Dean; Field, F. E.; Fowler, A. B.; Hatfield; Herendeen; Leuchars; Rexford; Taft.

Landscape Gardening.—Agar; Allen, L. F.; Barron; Brown, G.; Cleaveland; Cleveland; Cunningham; Doogue; Downing, A. J.; Elliott, F. R.; Ferree; Follen; Greening; Hemenway; Hooper, C. E.; Humphreys; Johnson, J. F.; Kellaway; Kemp; Kern, G. M.; Kern, M. G.; Leland; LeMoyne; Long; Manning, W. H.; Maynard; Meier; Meyer; Miller, C. H.; Murmann; Oakey; Parsons, S.; Platt; Powell, E. P.; Repton; Rogers, W. S.; Root; Rose; Sawyer; Scott, F. J.; Skinner, H.; Smith, C.; Tabor; Underwood, Loring; Van Rensselaer; Vaux; Waugh; Weidenmann; Wharton; Wild.

Mushrooms.—Falconer; Gardiner; Hard; Jackson; Jacob; Milliken; Mushrooms for All; Palmer; Peck.

Plant-breeding.—Bailey; DeVries; Harwood.

Propagation.—Bailey; Fuller; Howard; Jenkins, J.; Lelong.

Pruning, grafting, and spraying.—Bailey; Couts; Des Cars; Dollins; Larsen; Lodeman; Northrop; Sargent; Stedman; Weed, C. M.; Weed, H. E.; Whitten.

Trees.—Davey; Des Cars; Dollins; Egleston; Fernow; Meehan; Peets; Powell, E. C.; Roe; Solotaroff.

Vegetables and vegetable-gardening.—Allen, C. L.; Bailey; Bateman; Bennett, Ida; Bridgeman; Buist; Burpee; Burr; Complete Kitchen and Fruit Gardener; Cook; Corbett; Darlington; Davis, J. R.; Dreer; Every Man His Own Gardener; Fessenden; Fitch; French; Fullerton; Green, S. B.; Gregory; Greiner; Halsted; Hogg; Holmes, F.; Kennerly; Kiely; Kitchen and Fruit Gardener; Kruhm; Landreth; Lloyd; McNeil; Morse; Oemler; Provancher; Quinn; Rawson, N.; Rawson, W. W.; Rockwell; Rolfs.; Sevey; Skinner, H.; Stringfellow; Thompson, F. S.; Tillinghast; Turner, W.; Vick; Waldin; Warner, A.; Washburn & Co.; Watts; Wickson; Wilson; Winkler; Young.

Asparagus, special books: Herrmann; Hexamer.

Cabbage, special books: Allen, C. L.; Cook; Gregory; Landreth; Lupton; Pedersen; Tillinghast's Plant Manual.

Cauliflower, special books: Allen, C. L.; Brill; Crozier; Gregory; Lupton; Pedersen; Suffa.

Celery, special books: Beattie; Crider; Greiner; Hollister; Landreth; Livingston; Niven; Pratt; Rawson, W. W.; Roessle; Schuur; Stewart, H. L.; Tillinghast's Plant Manual; Van Bochove; Vaughan's Celery Manual.

Cucumber, special book: Collins.

Melons, special books: Blinn; Burpee; Troop.

Onion, special books: Gregory; Greiner; Landreth; Onion Book: Onions; Underwood, J. P.

Potato, special books: Best; Bosson; Carman; Cultivation of the Potato; Fitz; Fraser; Grubb; McLaurin; Matchette; Price, R. H.; Rogers, E. A.; Tenbrook; Terry; Van Ornam.

Squash, special book: Gregory.

Tomato, special books: Day; Livingston; Mitchell; Smith, F. F.; Taylor, H.; Tracy; Van Camp.

Water-gardening.—Bissett; Conard; Tricker.

Window-gardening.—Allen, Phoebe; Barnes; Casey; Dorner; Heinrich; Hillhouse; Holmes, J. H.; Mulertt; Rand, E. S.; Randolph; Rexford; Rockwell; Rose; Waugh; Williams, H. T.; Winter Gardening in a Bay Window.

Reports of horticultural societies and organizations.

Although the present discussion aims only to supply librarians and collectors with information as to what reports and series have been published, a brief sketch of the beginnings of horticultural societies in North America may supply a useful background or setting.

Although the year 1785 witnessed the establishment of the Philadelphia Society for Promoting Agriculture and the Agricultural Society of South Carolina, 1889 the Nova Scotia Society, and 1792 the organization of the Massachusetts Society for Promoting Agriculture, it was apparently not until 1818 that the first horticultural organization came into existence; this was the New York Horticultural Society, now extinct. The second, organized in 1827, was the Pennsylvania Horticultural Society, which is still in vigorous existence. The third, according to Manning, was the Domestic Horticultural Society, organized at Geneva, New York, in 1828, and which was the forerunner of the Western New York Horticultural Society, the latter having continued for more than fifty years. The next organization was apparently the Albany Horticultural Society, established in 1829, but which expired long ago. In 1829, also, the Massachusetts Horticultural Society was organized, an association which, in the character of the men who have been members and in the large service it has rendered to the advancement of rural taste, stands without a rival in the country. The American Pomological Society was organized in 1850 by a union of the North American Pomological Convention and the American Congress of Fruit-Growers, both of which were established in 1848. The Congress of Fruit-Growers was a meeting held in New York on the 10th of October, 1848, at the call of the Massachusetts, Philadelphia, New Jersey and New Haven Horticultural Societies and the Board of Agriculture of the American Institute of the City of New York. The Pomological Convention held its first meeting on the 1st of September in Buffalo. The American Pomological Society is undoubtedly the strongest organization of pomologists in the world. A. J. Downing wrote in 1852, that "within the last ten years the taste for horticultural pursuits has astonishingly increased in the United States. There are, at the present moment, at least twelve societies in different parts of the Union devoted to the improvement of gardening, and to the dissemination of information on the subject." At the present time there are over 500 such societies, and the average attendance at the meetings cannot be less, in the aggregate, than 20,000. From a careful estimate made in 1891, it was concluded that the aggregate attendance for that year at the national, state, provincial and district societies "probably exceeded 5,000."

There are now more than a dozen national societies devoted to horticulture or some branch of it. The most gratifying feature of this movement toward organization, however, is the establishment of great numbers of local societies, florists' clubs, and the like, which sustain the interest in horticultural pursuits and foster pride in the personal surroundings of the members. All this great body of societies is proof enough that there is a rapidly expanding and abiding love of horticulture in America, and that it must increase with the increasing amelioration of the country.

There are few state or provincial departments of horticulture, but most of the states and provinces have bureaus of agriculture and these may publish horticultural matter. In this discussion, however, only those official establishments that are specially organized for horticultural work are included.

REPORTS OF BOARDS AND SOCIETIES.

In the following paragraphs an effort is made to give such information as a librarian needs in the collecting of the published annual reports of existing national, state, provincial and regional horticultural societies in the United States and Canada, and of the reports of state and provincial boards, commissions, or departments of horticulture. The publications of these various bodies follow so many methods and there is often such lack of continuity in them that it is difficult to follow them as a whole and, particularly, to know when sets and series are complete. As an aid in determining some of these points, corollary information of the societies and boards is given: these pieces of information are intended only as secondary aids to the librarian and not as descriptions or histories of the organizations.

American Association of Nurserymen. An annual report is published by the society. The first report was published in 1890 under the title, "Proceedings of the American Association of Nurserymen." The publication is continuous under the same title. Total number of volumes, 24. There have been no special reports. Organized 1876. Address, 204 Granite Building, Rochester, N. Y.

American Association of Park Superintendents. This association has published six reports for the years 1908–13 inclusive. It has also issued eleven bulletins on special subjects relating to roads, walks, planting of parks, and the like. Address, United States Department of Agriculture, Washington, D. C.

American Carnation Society. Annual reports are issued by the society. The first report was published in 1891 under the title, "Annual Report of the American Carnation Society." The publication still continues under this title. Total number of volumes, 23. There have been no special reports. Address, Indianapolis, Ind.

American Cranberry Growers' Association. A semi-annual report is issued by the society. The first report was published in 1879 under the title, "New Jersey Cranberry Growers' Association." The publication has been continuous with one exception. Report of January meeting is entitled, "Proceedings of the Annual Meeting;" report of August meeting, "Proceedings of Annual Convention." Total number of volumes, 70. Address, Hammonton, N. J.

American Genetic Association, formerly called the American Breeders' Association. Annual reports were published for the years 1905–12, under the title, "Annual Report of the American Breeders' Association." Total number of volumes 8. From 1910–13, the "American Breeders' Magazine" was published quarterly. Beginning January, 1914, its name was changed to the "Journal of Heredity," which is published monthly, and the reports of meetings are published herein. Address, Washington, D. C.

American Gladiolus Society. This society issues a bulletin from time to time. The first annual report was published in Bulletin No. 1, August, 1910; the second in Bulletin No. 7. The publication is still continued in the "Modern Gladiolus Grower." Address 538 Cedar St., Syracuse, N. Y.

American Peony Society. This society issues no regular publications. The Nomenclature Committee of the society, in coöperation with a representative of the New York State College of Agriculture, has prepared four bulletins which have been published by Cornell University. The first appeared in 1907 under the title "A Peony Checklist;" the second in 1908, as Bulletin No. 259, "The Peony;" the third in 1910, as Bulletin No. 278, "The Classification of the Peony;" the fourth in 1911, as Bulletin No. 306, "The Classification of the Peony." The society holds an annual meeting and exhibition in June. Address, Clinton, N. Y.

American Pomological Society. Biennial reports are published by the society. The first report (for 1850) was published in 1851 under the title, "Report of the American Pomological Congress," and was published by the Ohio State Board of Agriculture. The next report was issued in 1852 under the title, "Proceedings of the Second Session of the American Pomological Congress." The publication has been continuous under the title "Proceedings of the American Pomological Society," with the exception of the years 1866 and 1893, when no reports were published. Total number of volumes, 29. There has been one special report entitled, "The Cherry, together with reports and papers on pear, plum, peach, grape, and small fruit." A "Catalogue of Fruits" has also been published by this society. Organized in 1850 by the union of two other societies, both organized in 1848. Address, 2033 Park Road, Washington, D. C.

American Rose Society. This society issues an annual bulletin under the title, "Annual Proceedings and Bulletin," the first bulletin being issued in 1905. From April, 1912, until the middle of the year 1913, it also issued a quarterly journal entitled, "The Rose Journal." Organized 1899. Address, Beacon, N. Y.

American Society of Landscape Architects. Has published one report of the transactions for the years 1899–1908 inclusive. The official organ of the society is a quarterly journal entitled "Landscape Architecture." Address, 15 East 40th St., New York City.

American Sweet Pea Society. This society was originally organized in New York, July 7 and 8, 1909, as the "National Sweet Pea Society of America." Annual exhibitions and conventions are held every summer. Extensive trials of sweet peas are carried on under the auspices of the horticultural department of Cornell University, Ithaca, N. Y. Bulletins are issued by Cornell University, which go to the members of this Society. Address, New York City.

Canadian Seed Growers' Association. Annual reports are issued by the Association. The first report was published in 1904, under the title "Report of First Annual Meeting of the Canadian Seed Growers' Association." The publication still continues under this title. Special bulletins are issued from time to time, the last one being "Plant Breeding in Scandinavia." Address, Ottawa.

Chrysanthemum Society of America. Annual meetings and exhibitions are held in November of each year of which an annual report is published together with the work of the committees. The first annual report was published in 1902. Address, Morgan Park, Ill.

International Apple Shippers' Association. This society issues an annual year-book, and a monthly bulletin. The first report was published in 1896 under the title, "International Apple Shippers' Association Year Book." Reports for 1900–1902 have the title, "Year Book of the National Apple Shippers' Association;" those for 1903–1909, "Year Book of the International Apple Shippers' Association;" those for 1910–14, "Official minutes of the International Apple Shippers' Association." A monthly bulletin began February, 1911, under the title, "The Spy." Both are continuous. There are special monthly reports issued for members only. Address, 612 Mercantile Bldg., Rochester, N. Y.

National Association of Gardeners. Official organ is the "Gardeners' Chronicle of America," which contains all the association news. Address, Madison, N. J.

National Council of Horticulture. Has issued no regular report except in 1907 of the Jamestown Congress of Horticulture. Copies of short articles on horticultural topics are sent to several thousand newspapers each spring.

National Nut Growers' Association. This association issues an annual volume of proceedings and also a journal, "The Nut Grower," which is the official organ of the society, and consists of 24 pages monthly. It began publication in August, 1902. The first report was published in 1903 under the title, "Proceedings of the Second Annual Convention." There have been seven issues under the title "Proceedings of the Annual Conventions." There have been no special reports. Address, Cairo, Ga. Northern Nut Growers' Association. See *Nuts*, Vol. IV.

Railway Gardening Association. Reports of the annual meetings are published. The seventh report was issued in 1913. Address, Sewickley, Pa.

Society of American Florists and Ornamental Horticulturists. An annual report is published by the society. The first report was published in 1885 as "Proceedings of the Society of American Florists." After 1901, the title was changed to "Proceedings of Society of American Florists and Ornamental Horticulturists." Have also published a list of plants registered from July, 12, 1908 to August 1, 1914. National charter given March 3, 1901. Address 53 West 28th St., New York City.

Society for Horticultural Science. This society issues an annual report entitled, "Proceedings of the Society for Horticultural Science." The first report was published in 1905 under the title, "Proceedings of the Society for Horticultural Science. Preliminary meeting, September. 1903; first annual meeting, December, 1903; second annual meeting, 1904." Proceedings have been published annually since with the exception of the year 1908, which was published with 1909. Total number of volumes, 9. Address, College Park, Md.

Vegetable Growers' Association of America. The first report was published in 1909 under the title, "Year Book of the Greenhouse Vegetable Growers' and Market Gardeners' Association of America." The next report contained the proceedings of the conventions of 1909, 1910 and 1911 and appeared under the title, "Official Proceedings of the Vegetable Growers' Association of America." The proceedings of the 1912 convention will probably be published with those of 1913 and 1914. Address, Louisville, Ky.

ALABAMA

Alabama State Board of Horticulture. The first report was published in 1903–4 under the title, "First Annual Report of the Alabama State Board of Horticulture." Only the first two reports have been published and these by the state. They have been published under one cover and also separately. Those from 1905–6 to 1911–12 are typewritten reports submitted to the Governor. There have been no volumes or reports on special subjects. This board is chiefly concerned with nursery inspection and the enforcement of the horticultural law approved March 5, 1903. The board consists of the Commissioner of Agriculture, president of the State Horticultural Society, director of the experiment station (ex-off.). The horticulturist of the experiment station is secretary of the board and State Horticulturist. Address, Auburn.

Alabama State Horticultural Society. This society issues annual reports which are published by both the state and the society. The first report was published in 1904 under the title, "Proceedings of the Alabama State Horticultural Society, First Annual Meeting." The publication is still continued under the title, "Proceedings of the Alabama State Horticultural Society." The first, second, third, and fourth annual reports were published by the society; the fifth, sixth and seventh were published in one volume by the Department of Agriculture, Montgomery, as serial No. 36, and the eighth annual report as a Department bulletin, serial No. 42. The ninth, tenth and eleventh annual reports have recently been issued by the society. Total number of volumes, 11. There have been no separate reports on special subjects. Organized January 27, 1903. Address, Auburn.

ARIZONA

Arizona Commission of Agriculture and Horticulture. This commission issues annual reports and circulars, published by the state. The first report was published in August, 1909, under the title, "First Annual Report of the Arizona Horticultural Commission." Four reports have been published under the title, "Annual Report of the Arizona Horticultural Commission." In 1912, the name of the organization was changed as above and two reports have been published under the title "Annual Report Arizona Commission Agriculture and Horticulture." The annual reports of the State Entomologist are included in the reports of the commission. Sixteen circulars have been published on various entomological subjects. Address, Phoenix.

ARKANSAS

Arkansas State Horticultural Society. Annual reports are published by the society. The first report was published in 1900 under the title, "Annual Report of the Arkansas State Horticultural Society." The publication has been continuous under this title. Total number of volumes, 13, but this does not include two reports which were issued in 1894, (First and Second Annual Reports, 1893–4). At that time, a new society had been organized under the same name as the old horticultural society founded in 1879. The second society was finally merged into the first. Address, Horticultural Department, University of Arkansas, Fayetteville.

BRITISH COLUMBIA

British Columbia Fruit Growers' Association. An annual report is published by the province. The first report was published in 1890 under the title, "First Annual Report of the British Columbia Fruit Growers' Association." The reports from 1892–1895 have the title, "Annual report of the Horticultural Society and Fruit Growers' Association of British Columbia;" those from May, 1895, to August, 1897, "Report of the British Columbia Fruit Growers' and Horticultural Society;" those from 1908–9, "Annual and Quarterly Meetings of the British Columbia Fruit Growers' Association." The twenty-fourth annual report was issued in 1913. There have been no special reports, except a "Pest and Remedy" supplement, 1895–6, issued separately. Address, Victoria.

CALIFORNIA

California Association of Nurserymen. This organization has published four reports, the first entitled, "Transactions and Proceedings of the First Annual Meeting of the California Association of Nurserymen, held . . . 1911." Address, Los Angeles.

California State Board of Horticulture. The reports of this board have been published in six series. The first series consisted of one annual report published in 1883; the second of unnumbered biennial reports; the third of unnumbered annual reports; the fourth of numbered biennial reports beginning with No. 4; the fifth of numbered biennial reports beginning with No. 1. A series of bulletins have been published from 1883–1900 numbered from 1–71. It is doubtful, however, whether any were issued between 8 and 50. Five non-serial reports were issued between 1886 and 1901 consisting of reports of committees, library catalogues and the like. Separate reports have also been issued of the proceedings of the Fruit Growers' Convention. The first report issued by this board was published in 1883 under the title, ' Third Annual Convention of the Fruit Growers of the State of California." Reports of succeeding conventions have been published, either in separate form or in the report of the State Board (later in the report of the State Commission), with the exception of the twentieth to twenty-third conventions which were never published. At least three state conventions of olive-growers have been held under the auspices of the State Board of Horticulture, 1891–3, for which separate reports have been issued. These have appeared under the title "Olive Industry. Proceedings of the State Convention of Olive Growers, held under the auspices of the State Board of Horticulture." Organized March 4, 1881, as a subsidiary board to the State Board of Viticultural Commissioners. On March 13, 1883, became independent by Act of Legislature.

California State Board of Horticultural Commissioners. This board published a report in 1882 entitled, "First Report of the Board of State Horticultural Commissioners," covering the work from 1880–2; also proceedings of first and second Fruit Growers Convention.

California State Board of Viticultural Commissioners. Published seven annual reports for the years 1880–94. Of the first report, 1880, two editions were issued. The third report, 1882–4, was published in, or rather was identical with, the report of the chief viticultural officer for those years. There were also issued separately two annual reports of the chief viticultural officer, the first for 1881, published 1882, the second for 1882–3 to 1883–4 (being the one just mentioned). Later reports of the viticultural officer are contained in the annual reports of the board. Two publications, "Grafting to Muscats" and "Wines, Their Care and Treatment," issued in 1888 and 1889, are called Appendix 4 and 5 respectively of the report for 1888, but no report for 1888 seems to have appeared. However, there was issued a report of proceedings of sixth annual viticultural convention and the report of the president of this board. These may have constituted the report for this year.

California State Commission of Horticulture. This organization has grown out of the original State Board of Horticulture. It publishes a biennial report. The first report, 1903–4, was issued under the title, "First Biennial Report of the Commissioner of Horticulture." Total number of volumes, 6. Reports of the forty-third and forty-fourth State Fruit Growers' Conventions were not published. Monthly bulletins have been published since December 1911. Address, Capitol Building, Sacramento.

COLORADO

Colorado State Board of Horticulture. The first report was issued in 1884. Reports have been published continuously since then, with the exception of the year, 1895–6, which was never published. There has been considerable variation in the title, and the reports have been sometimes annual, sometimes biennial, the first covering three years. Up to 1886, the name of the body was Colorado State Horticultural Society; 1887–90, Colorado State Horticultural and Forestry Association; 1891–2, Colorado State Bureau of Horticulture; 1893 to 1913, Colorado State Board of Horticulture. In 1913, the State Board of Horticulture was abolished, and the office of State Horticulturist created. The report of the State Horticulturist will take the place of the Annual Report of the Board of Horticulture. Total number of volumes, 24. Address, Fort Collins.

CONNECTICUT

State Pomological Society. This society has published an annual report for the past 15 years. The first report was issued under the title "A brief record of the work of the Connecticut Pomological Society," in 1900. Total number of volumes, 16. Organized in 1891. Address, Milford.

DELAWARE

Peninsula Horticultural Society. An annual report is published by the society. The first report was published in 1888 under the title, "Transactions of the Peninsula Horticultural Society." The publication is still continued under this title. Total number of volumes, 27. Volume XIV was issued in two parts, Part I, the Proceedings of the annual session of 1901 and Part II, a pamphlet of 80 pages on "The Principal Pests and Diseases of the Apple Orchard." Address, Dover. (This society includes also a part of Maryland and Virginia.)

FLORIDA

Florida State Horticultural Society. An annual report is published by the society. The first report was published in 1892 under the title, "Transactions of Florida State Horticultural Society." This title was continued up to 1909 when it changed to "Proceedings of the Florida State Horticultural Society." The publication has been continuous. Total number of volumes, 22. Special papers on flowers, fruits, vegetables and the like appear in the reports but are not published separately Organized in 1887. Address, Jacksonville.

GEORGIA

Georgia State Horticultural Society. Annual reports are issued, now published by the society. The first report was published in 1877 under the title, "Proceedings of Georgia State Horticultural Society." The publication is still continued. The first to thirtieth reports were published by the society. The next five were published by the State Board of Entomology,—Bulletins Nos. 25, 27, 30, 33, 35. The report for 1912 was published by the State College of Agriculture as a part of the report of the Fourth Annual Farmers' Conference held in 1912. The thirty-eighth report, for 1914, was published as a bulletin of the State College of Agriculture, Vol. 2, No. 12. This report was afterward published separately by the society. Total number of volumes, 38. There have been no special reports. Address, College of Agriculture, Athens.

North Georgia Fruit Growers' Association. The society has issued two reports, the first entitled, "Proceedings of the Sixth Annual Session of the North Georgia Fruit Growers' Association . . . 1902." A report of the seventh session for 1904 is also published.

HAWAIIAN ISLANDS

There is no separate horticultural organization, only the Board of Commissioners of Agriculture and Forestry.

IDAHO

Idaho State Horticultural Association. An annual report is published by the society. The first report was published in 1904 under the title, "Annual Report of the Idaho State Horticultural Association." The publication has been continuous under this title. Total number of volumes, 9. There have been no special reports. Address, Boise.

ILLINOIS

Illinois State Horticultural Society. Annual reports are published by the society. The first report was published in 1856 under the title, "Transactions of the Illinois Horticultural Society." The publication is still issued under this title. The report of the first annual meeting was published in Volume II of the Illinois Agricultural Society Transactions. There was no report of the second annual meeting. The third meeting was published in Volume III, Illinois Agricultural Society Transactions, the fourth in the Prairie Farmer, the fifth in Volume IV, Agricultural Society Transactions, sixth, seventh (these two bound in one volume), and eighth in pamphlet form, ninth in Volume V, Agricultural Society Transactions, tenth in pamphlet form and the eleventh in a bound volume. The proceedings of the twelfth annual meeting were issued as Volume I New Series. There have been 47 issues in this series to date. Total number of volumes is as follows: Four reports bound in the Transactions of the Illinois Agricultural Society, 1 in the Prairie Farmer, 4 pamphlets and 46 bound volumes. The only special report ever published was of the Society's Exhibit at the World's Fair in 1893. Beginning with March, 1913, has issued a quarterly journal entitled "Illinois Horticulture." Address, Normal.

Horticultural Society of Central Illinois. This society issues annual reports that are published in the Transactions of the State Horticultural Society.

Horticultural Society of Northern Illinois. The annual report of this society is published in the transactions of the state society. The transactions of the first and fourth meeting, 1867–8, 1871, were also published in separate form. The first has the title, "Transactions of the Northern Illinois Horticultural Society embracing the first organization and meeting . . . December 18, 1867. With the proceedings and essays at the first annual meeting . . . February 13, 1868."

Horticultural Society of Southern Illinois. The annual report of this society is also published in the report of the state society.

INDIANA

Indiana Horticultural Society. This society issues an annual report published by the state. The first report was published in 1866 under the title, "Transactions of the Indiana Horticultural Society." The publication has been continuous under the one title. Total number of volumes, 53. Bulletins on special subjects were published by the society from 1904–11. Organized 1860. Address, W. Lafayette.

IOWA

Iowa State Horticultural Society. Annual reports, published by the state, are issued by this society. The first report was issued in 1868 under the title, "The Proceedings of the Iowa State Horticultural Society, for 1866–7." From 1871–7, the reports have the title "Annual Report;" from 1878–90, "Transactions;" and from 1891 to the present time, "Report." Total number of volumes, 47. The reports from 1866–70 were bound with the agricultural report and also in paper separates; since that time, they have been bound as separate volumes. The society has issued seven bulletins: "Forestry Manual," 1881; "Plants of Iowa," 1907; "Iowa Horticulture," 1908; "Proceedings Iowa Park and Forestry Association," 1904, 1905, 1906, 1907." Address, Des Moines.

KANSAS

Kansas State Horticultural Society. This society issues biennial reports published by the state. The first report was published in 1871 under the title, "Condensed Transactions of the Kansas State Pomological and Horticultural Society from its organization to its last annual meeting, and in full for the year 1871.' From 1877–86, the reports were issued under the title, "Kansas Horticultural Report;" from 1887–95, "Biennial Report of the Kansas State Horticultural Society." The reports up to 1887 and for 1896–1901 were published annually. Total number of volumes, 32. Special reports have been published on forestry, apple, peach, plum, grape, cherry and apricot. Address, State House, Topeka.

KENTUCKY

Kentucky State Horticultural Society. A few publications have been issued by this society at long intervals, but no complete records of these are available. In 1865, a report was published under the title "Report of the Kentucky State Pomological Society;" in 1881, "Proceedings of the Kentucky Horticultural Society at its annual meeting, Jan. 13, 14 and 15, 1880." The Proceedings for 1907 were published in the Report of the Bureau of Agriculture, Labor and Statistics for 1907. The report for 1911 was issued as "The Report of the Kentucky State Horticultural Society" and was also published in the Report of the Bureau of Agriculture, Labor and Statistics for 1911. There was no report for 1912. The report for 1913 was also published in the Report of the Bureau of Agriculture. etc. The report for 1914 was issued as "The Report of the Kentucky State Horticultural Society." Address, College of Agriculture, Lexington.

LOUISIANA

Louisiana State Horticultural Society. This society issues no reports at present and held no meetings from 1908–1912. Previous to this time, however, annual reports were issued by the state. The first report was published about 1901 under the title, "State Horticultural Society Proceedings." From 1904–8, five volumes were issued as "Proceedings of the Annual Meeting." The last meeting of the old horticultural society was held in 1908 and in 1912 it was reorganized and holds annual meetings at the State University, Farmer's Short-course in January of each year. Address, Baton Rouge.

MAINE

Maine State Pomological Society. Annual reports are published by the society. The first report was published in 1873 under the title, "Annual Report of the Maine State Pomological Society." Reports have been published continuously except for the years 1879, 1880 and 1881. Abstracts from the Transactions of these years were published as an appendix to the Transactions for 1890. In 1882, the title was changed to "Transactions of the Maine State Pomological Society." In most cases, these reports have also been contained in the report of the Commissioner of Agriculture. Organized in 1873. Address, Bowdoinham.

MANITOBA

Manitoba Horticultural and Forestry Association. Annual reports are published by the association. The first report was issued in 1898 under the title, "Report of Proceedings of the Western Horticultural Society for the years 1896–8." The publication is still continued but in 1911, the name of the society was changed to "Manitoba Horticultural and Forestry Association." They were published as biennial reports from 1896–8 and 1901–2, as a triennial report for 1902–5 and as annual reports from 1898–1900 and 1906–9. No report for 1910. Annual report for 1911 and biennial report for 1912–13 and 1914 have been published. Total number of volumes, 12. A few short papers have also been published by the Association. In April 1914, a monthly publication known as the "Manitoba Horticulturist" was issued by the association. Future annual reports will consist of bound copies of the year's issue of this monthly, together with a short account of the annual meeting. Address, Agricultural College, Winnipeg.

MARYLAND

Maryland State Horticultural Society. An annual report is issued, published by the society. The first report was published in 1898 under the title, "Report of the Maryland State Horticultural Society." The publication is continuous under this title. Total number of volumes, 16. There have been no special reports. Address, College Park.

MASSACHUSETTS

Massachusetts Asparagus Growers' Association. Formed in 1906 to promote the restoration of asparagus to its immunity from rust, or the discovery of a species that shall be rust-resistant, and the dissemination of information in relation to its growing and marketing. Is in close touch with the coöperative experiments carried out at Concord by the United States Department of Agriculture and the Agricultural Experiment Station at Amherst. The association holds an annual field-day in September and publishes a report of the proceedings. Bulletin No. 263, United States Department of Agriculture by J. B. Norton is devoted to these experiments. Address, Concord.

Massachusetts Horticultural Society. This society publishes its own annual report. The first report was issued in 1829 under the title, "Massachusetts Horticultural Society." One number, March, 1859, was published under the title, "The Journal of the Proceedings." The publications have been continuous since 1839. It was formerly published in one volume once a year, but since 1874 it has been published in two parts annually or occasionally in three, as in the case of 1895–7. There are numerous special articles in the Transactions on the culture of flowers, fruits and vegetables. The society has also issued the following publications: in 1862, "Properties of Plants and Flowers;" in 1864, "Proceedings on the occasion of the laying of the corner-stone of the new hall;" in 1873, a "Catalogue of the Library;" in 1880, "History of the Massachusetts Horticultural Society, 1829–78;" in 1889, "Window Gardening, and a list of some of the flowers found growing naturally in the vicinity of Boston." Address, Horticultural Hall, Boston.

MICHIGAN

Michigan State Horticultural Society. This society issues an annual report published by the state, and also a monthly journal called "Michigan Horticulture." The first report was published in 1870 under the title, "Annual Report of the Michigan State Pomological Society." The publication has been continuous with the exception of the year 1904, when no report was published. The report for 1905 is in the back of the report for 1906. The title was changed in 1881 to "Annual Report of the State Horticultural Society." Total number of volumes, 42. Address, Fennville.

MINNESOTA

Minnesota State Horticultural Society. An annual report and a monthly magazine entitled, "Minnesota Horticulturist," are published by the state. The first report was published in 1873 under the title, "History of the Minnesota Horticultural Society from the first meeting in 1866, to the last in 1873, comprising debates, addresses, essays and reports." Reports for 1874–82 have the title, "Transactions." The Minnesota Horticulturist began publication in February, 1894, with Vol. 22, the volume number of the annual report for that year, and continues this system of numbering. The publication is still continued, but in 1899 the title was changed to "Trees, Fruits and Flowers of Minnesota." This comprises the 12 monthly journals and the annual report of the society, bound together. Total number of volumes, 43. There have been no special reports. Address, 207 Kasota Block, Minneapolis.

MISSISSIPPI

A State Horticultural Society existed about twenty-five years ago and published one or two reports.

MISSOURI

Missouri State Board of Horticulture. The Board issues an annual report published by the state. The first report was published in 1907 under the title, "Annual Report of the State Board of Horticulture." The publication has been continuous under the same title. The publications of the State Horticultural Society since 1907 have been included in the Reports of the State Board. Total number of volumes, 7, the last being chiefly taken up by orchard census of the state of Missouri taken in 1913. There have been 67 bulletins published on various phases of fruit-growing, vegetable-growing and the like, most of which are reprints of special articles from the reports. Two circulars and ten pamphlets have also been issued Address, Columbia.

Missouri State Horticultural Society. From 1857–1907, annual reports were issued. These comprise 50 volumes, published by the state. They were published under the title, "Reports of the State Horticultural Society." The report is now embodied in the Report of the State Board. In the past ten years, this society has issued a number of special bulletins. Address, Mountain Grove.

MONTANA

Montana State Board of Horticulture. Biennial reports are published by the state. The first report was published in 1900 under the title, "First Biennial Report of the State Board of Horticulture." The publication is still continued under the above title. Total number of volumes, 6. There have been no special reports. Address, Missoula. The 1914 report will be combined in the volume of the report of the Horticultural Society.

Montana State Horticultural Society. This society issues annual reports published by the state. The first report was published in 1907 under the title, "Proceedings of the Ninth Annual Session of the Montana Horticultural Society." The publication has been continuous under the same title. In connection with the fifteenth report, is the first report of the Country Life Commission. In January, 1902, there was printed a series of papers in pamphlet form, including the constitution and by-laws of the society. Total number of volumes, 8. There have been no special reports. Address, Missoula.

NEBRASKA

Nebraska State Horticultural Society. An annual report is published by the society. The first report was published in 1870 under the title, "Annual Report of the State Horticultural Society," and was printed in the same volume as the report of the State Board of Agriculture. The publication is still published under this title. Thirty-two bulletins on particular phases of horticulture have been published. Since February, 1911, the society has published a monthly journal, "Nebraska Horticulture." Total number of reports, 45. Address, Capitol Building, Lincoln.

NEVADA

There are no horticultural societies in Nevada.

NEW BRUNSWICK

New Brunswick Fruit Growers' Association. This society issues annual reports published by the province. The first report was published in 1905 in the "Report on Agriculture for 1904," issued by the Department of Agriculture. The publication is continuous. Up to 1911, the reports were published in the annual report of the Department of Agriculture. The Report of the Horticultural Division, Department of Agriculture, was combined with the report of the association for 1910 and published as a separate document in that year. Total number of reports, 9. No special reports. Address, Fredericton.

Horticultural Division, New Brunswick Department of Agriculture. The first annual report was published in 1910 in the general report of the Department. In 1911, a separate report was published with the association report. The division publishes leaflets and bulletins on special subjects. Established in 1910. Address, Fredericton.

NEW HAMPSHIRE

New Hampshire Horticultural Society. Annual reports are published by the society. The first report was published in 1908 under the title "Annual Report of the New Hampshire Horticultural Society." The publication has been continuous under the same title, except for the year 1911. There have been no special reports. Organized in 1893. Address, Goffstown.

NEW JERSEY

New Jersey State Horticultural Society. This society issues an annual report published by the state. The first report was published in 1876 under the title "Proceedings of the New Jersey State Horticultural Society at its Annual Meeting." The publication is continuous under the same title. Total number of volumes, 39. There have been no special reports. Organized in 1875. Address, Riverton.

NEW YORK

Eastern New York Horticultural Society. This organization is now a part of the New York State Fruit Growers' Association.

Horticultural Society of New York. A quarterly journal containing the reports of proceedings and the like is published by the society. Also memoirs devoted to special subjects are issued. Vol. I. "Report of Second International Plant Breeding Conference," 1902; Vol. II. "Report of International Conference on Acclimatization," 1900. Address, New York Botanical Garden. Society organized 1900; incorporated 1902.

New York State Fruit Growers' Association. Annual reports and crop bulletins are issued, published by the society. The first report was published in 1903 under the title, "Proceedings of the Annual Meeting." The publication is still continued under this title. Total number of volumes, 13. There have been no special reports. Address, Penn Yan.

New York State Vegetable Growers' Association. Organized 1911; has published two volumes of proceedings. Address, Ithaca.

Western New York Horticultural Society. The first annual report was issued in 1874 under the title, "Proceedings of Western New York Horticultural Society." The publication still continues under the same title. Total number of volumes, 40. There have been no special reports. Established 1855. Address, 204 Granite Building, Rochester.

NORTH CAROLINA

Division of Horticulture of the North Carolina Department of Agriculture. The reports of the Division of Horticulture are included in the Department reports. Biennial reports have been published since 1900, making seven to date. Monthly bulletins have been issued since 1879 by the Department, only a few of which are strictly horticultural. There are 35 volumes in this series. Special horticultural circulars are also issued from time to time. Address, Raleigh.

North Carolina State Horticultural Society. This society has not been in active existence for some years but it is now in process of reorganization. A few annual reports, however, have been issued, those for 1886, 1893, 1894, 1898 and 1906. There have been issued separately five reports of the Experimental Farm of the society at Southern Pines. They have also published the following special bulletins: "The Cow Pea," "Plant Food," and "Truck Farming."

NORTH DAKOTA

North Dakota Horticultural Society. No reports published. Members receive those published by the Minnesota Horticultural Society.

NOVA SCOTIA

Nova Scotia Fruit Growers' Association. An annual report is published by the society. The first report was published in 1875 under the title, "Report of the Fruit Growers' Association and International Show Society of Nova Scotia." No other reports were published until 1883. Those from 1883–1894 bore the title, "Transactions and Reports of the Fruit Growers' Association and International Show Society of Nova Scotia;" those from 1895 to the present time, "Annual Report of the Fruit Growers' Association of Nova Scotia." The publication is continuous under the same title. Total number of volumes, 31. Address, Port Williams.

OHIO

Columbus Horticultural Society. Annual reports published by the society are issued. From 1845–1886, the proceedings of the monthly meetings were published in Columbus newspapers. From 1886–1890, a journal was issued monthly and from 1890–1895, this journal was issued as a quarterly. These publications were entitled "Journals of the Columbus Horticultural Society." From 1890 to the present time, the society has published an annual report under the title, "Proceedings of the Columbus Horticultural Society." Total number of volumes, 27. Address, Columbus.

Division of Horticulture of the Ohio Department of Agriculture. This organization has issued at least three bulletins, 1907–1909.

Ohio State Horticultural Society. This society was organized in 1847 as the "Ohio Pomological Society," whose first report was published in 1848. In 1866, the name of the society was changed to the "Ohio State Horticultural Society." This society issues an annual report. The first report was published in 1868 under the title "Annual Report of the Ohio State Horticultural Society (late Pomological Society)." Reports for 1907–8 are published in Bulletins Nos. 1 and 3 of the Division of Horticulture of the Ohio Department of Agriculture. Since 1908, the annual reports have been issued independently. Quarterly bulletins have been issued during the past three years. Total number of volumes, 47. Address, Newark.

OKLAHOMA

Oklahoma State Fruit Growers' Association. Issues no publications.

ONTARIO

Fruit Branch of the Ontario Department of Agriculture. Annual reports, published by the province, are issued. The first report was published in 1909 under the title, "Annual Report of the Fruit Branch of the Ontario Department of Agriculture." This publication is now incorporated in the annual report of the Minister of Agriculture. From 1894–1907, a separate report, "The Fruit Experiment Stations of Ontario," was published by the Department. This was merged with the Fruit Branch in 1908. Total number of volumes, 14. A special report on "Fruits of Ontario" was published in 1906 and revised in 1914. Special reports on fumigation and, orchard spraying were issued for a few years but are now combined with the Report of the Fruit Branch. Complete bulletins of every fruit grown in Ontario and also on special horticultural subjects are issued and revised from time to time as part of a regular series of bulletins published by the Ontario Department of Agriculture. Address, Parliament Buildings, Toronto.

Fruit Growers' Association of Ontario. This society issues an annual report published by the province. The first report was published in 1863 under the title, "Report of the Fruit Growers' Association of Upper Canada." The publication is continuous, but "Ontario" has been substituted for "Upper Canada." Total number of volumes, 49. Address, Parliament Buildings, Toronto.

Horticultural Societies of Ontario. This organization publishes an annual report. The first report was published in 1907 under the title, "First Annual Report of the Horticultural Societies of Ontario." Total number of volumes, 8. Address, Parliament Building, Toronto.

Ontario Vegetable Growers' Association. This society was organized in 1909 and has held annual meetings since that time. Proceedings of all the meetings are published. Address, Parliament Buildings, Toronto.

OREGON

Oregon State Board of Horticulture. This board issues biennial reports published by the state. The first report was published in 1891 under the title, "Biennial report of State Board of Horticulture." The publication is continued under the above title. Total number of volumes, 12. There have been special bulletins issued on fruits, spraying, orchard management and the like. They have issued at least nine numbered bulletins of which 1–3 may be found in the first biennial report and 5–7 in the second. Address, Portland.

Oregon State Horticultural Society. An annual report is published by the state. The first report was published in 1909 under the title, "Proceedings and Papers of the Twenty-fifth Annual Meeting of the Oregon State Horticultural Society." In 1892, one report was published in connection with the Report of the State Board of Horticulture. The publication is continued under the title "Proceedings and Papers of the Annual Meeting of the Oregon State Horticultural Society." Total number of volumes, 5. There have been no special reports. Address, Portland.

PENNSYLVANIA

State Horticultural Association of Pennsylvania. Annual reports are published, usually by the society, but from 1878–1894 they were published in connection with the reports of the State Board of Agriculture of Pennsylvania. The report for 1895 was issued as Bulletin 8 of the State Board of Agriculture; those for 1896 and 1899–1906 were published in the annual report of the Department of Agriculture. The first report was published sometime between 1860 and 1867 under the title, "Report of Eastern Pennsylvania Fruit Growers' Society." Later, it was issued under the title, "Report of Pennsylvania Fruit Growers' Society." After 1881, it appeared under the title, "Report of State Horticultural Association of Pennsylvania." The publication has been continuous with the exception of the year 1897, which was never published. There have been no special reports. Organized in 1860. Address, Flora Dale.

PORTO RICO

Porto Rico Horticultural Society. Only one report has been published, that of 1911–12, under the title, "First Annual Report of the Porto Rico Horticultural Society." From July, 1908, to October, 1910, the "Porto Rico Horticultural News" was issued monthly as the official organ of the Porto Rico Horticultural Society. In December, 1910, this journal was merged with "Porto Rico Progress" which has since been issued weekly. Address, Mayaguez.

PRINCE EDWARD ISLAND

Fruit Growers' Association of Prince Edward Island. This society issues annual reports published by the Department of Agriculture. The first report was published in 1896 under the title, "First Annual Report of the Fruit Growers' Association of P. E. I." The publication is still continued under this title. Some of the reports are bound with the Report of the Department of Agriculture and are not published separately. Total number of volumes, 15. There have been no special reports. Address, Charlottetown.

QUEBEC

Montreal Horticultural Society and Fruit Growers' Association of the Province of Quebec. This society published its first annual report in 1876 under the title, "First Report of the Fruit Committee of the Montreal Agricultural and Horticultural Society." The second report was entitled "Transactions and Second Report of the Fruit Committee, etc," and was published in 1877. From 1877–1882, the reports have the title "Report of Montreal Horticultural Society and Fruit Growers' Association of the Province of Quebec." Later reports have the same title with the words "Annual Report" substituted for "Report." The society has not been in active existence since about 1893 and no recent reports have been published.

Pomological and Fruit Growing Society of the Province of Quebec. Annual reports and pamphlets are issued, published by the society but paid for by the Government. The first report was published in 1895 under the title, "Annual Report of the Pomological and Fruit Growing Society of the Province of Quebec." The publication is continuous under this title. Total number of volumes, 21. There have been no special reports. Chateauguay.

RHODE ISLAND

Rhode Island Horticultural Society. This society issues no publications except premium lists for its exhibitions. Address, Providence.

SOUTH CAROLINA

Horticultural Society of South Carolina. This society is not now in existence. It published only one report in 1889 entitled "Report of the First Meeting of the State Horticultural Society."

South Carolina Fruit Growers' Association. This society was organized about six years ago but has held only one meeting. No publications have as yet been issued. Address, Greenville.

SOUTH DAKOTA

South Dakota State Horticultural Society. This society issues an annual report published by the state. The first report was published in 1904 under the title. "First Annual Report of the Thirteenth Meeting." The publication is continuous under the title, "Annual Report." Total number of volumes, 11. There have been no special reports. Incorporated under state law, January 9, 1890. Address, Brookings.

TENNESSEE

Tennessee State Horticultural Society. Annual proceedings are issued, beginning with 1914.

Tennessee State Nurserymen's Association. Proceedings are issued annually, the first appearing in 1914. Address, Knoxville.

TEXAS

Texas Nurserymen's Association. This association holds annual meetings, reports of which are published in the reports of the Texas Farmers' Congress. No special reports are issued. Address, Sherman.

Texas Nut Growers' Association. This association was organized in 1904 and continued until July, 1910, when it was merged into the State Horticultural Society. One bulletin on pecans was published with the proceedings of the Texas Farmers' Congress; "Pecans and Other Nuts in Texas," 1908. "The Pecan and Hickory in Texas," by E. J. Kyle was published by the Texas Department of Agriculture in bulletin form in 1911.

Texas State Horticultural Society. An annual report is published in the general proceedings of the Texas Farmers' Congress, published by the Department of Agriculture, bulletin form. In 1889, there was a report published by the society containing the reports of meetings from 1886–1889 under the title, "Initial Report of the Texas State Horticultural Society." No other reports were published until about 1905 when they were included in the Farmer's Congress Report. There are no special reports. Address, College Station.

UTAH

Utah State Horticultural Commission. This organization publishes a biennial report. The first report was issued in 1897 under the title, "Report of the State Board of Horticulture." Reports from 1897–1908 have the title, "Biennial Reports of the State Board of Horticulture;" 1909–1910, "Biennial Report of the State Horticultural Commission." Total number of volumes, 9. There have also been at least 9 numbered bulletins, the first six numbers of which appear also in the annual reports. Address, 412 Vermont Building, Salt Lake City.

Utah State Horticultural Society. An annual report is issued by the society. The first report was published in 1912 under the title, "Proceedings of the Sixth Annual Convention of the Utah State Horticultural Society." A report of the eighth annual convention, 1912, has been issued. Organized 1905. Address as above.

VERMONT

Vermont State Horticultural Society. This society issues annual reports published by the state in "Vermont Agriculture" and also as separates. The first report was published in 1896 under the title, "Report of First Annual Meeting of Vermont State Horticultural Society." No other report was published until 1905, when there was issued the "Second Annual Report of the Vermont State Horticultural Society, Proceedings of the Tenth Annual Meeting." The publication is continuous. Total number of volumes, 12. There have been no special reports. Address, Burlington.

VIRGINIA

Virginia State Horticultural Society. An annual report is issued by the society (which has state appropriation). The first report was published in 1898 under the title, "Annual Report of the Virginia State Horticultural Society." The publication is still continued under this title. The society issues four quarterly bulletins each year, the first issue containing a revised "Spray Calendar." Have also published "Fruit Growing in Virginia," and "Packing Apple Book." Address, Crozet.

WASHINGTON

Washington State Horticultural Association. Annual reports and bulletins are published by the society. The first report was issued in 1901 under the title, "Report of the Washington State Horticultural Association." The publication still continues under the same title. Total number of volumes, 9. There have been no special reports. Address, State Secretary's Office, Walla Walla.

WEST VIRGINIA

West Virginia State Horticultural Society. Up to 1913 this society issued an annual report published by the State Board of Agriculture as one of its quarterlies. The first report was published in 1894 under the title, "Special Bulletin No. 2, State Experiment Station." The second, third, fourth and fifth annual meetings were reported in the "Farm Reporter" (no longer published), sixth, seventh and eighth in the "Farm Review" (no longer published), ninth in pamphlet form, tenth, eleventh and twelfth in "Farm Review," and the thirteenth to nineteenth have been issued by the State Board of Agriculture. The twentieth report is published by the Commissioner of Agriculture, as the Board of Agriculture has been disbanded. There have been no special reports. Address, Morgantown.

WISCONSIN

Wisconsin State Cranberry Growers' Association. This association has issued twenty-seven annual reports and ten semi-annual reports. The first report was issued in 1887.

Wisconsin State Horticultural Society. An annual report is published by the state. The first regular report was published in 1871 under the title, "Transactions of the Wisconsin State Horticultural Society." Beginning with the report for 1889, the publication bore the title, "Annual Report." Since 1910, the report has been issued in two parts: Part I, containing constitution, by-laws, business transactions and list of members which are for distribution to members only. In 1868, a report was published entitled, "Report for the years 1864–8, with a short historical sketch since its organization." This society also issues a monthly magazine entitled, "Wisconsin Horticulture," the first issue of which appeared in September, 1910. Between 1896 and 1903, a monthly periodical, entitled "The Wisconsin Horticulturist," was issued. Nineteen numbered bulletins have appeared between March, 1903, and April, 1910. Address, Madison.

WYOMING

Wyoming State Board of Horticulture. Biennial reports are issued. The first report was published in January, 1907, under the title, "Biennial Report of the Wyoming State Board of Horticulture." The publication is continued under the same title. Special bulletins, alternating with the reports, are published—four have been issued thus far,—1908, 1910, 1912, 1914. Address, Laramie.

Wyoming State Horticultural Society. Proceedings are issued in publications of the above board, those bearing the odd numbers in the biennial reports, and the others in the special bulletins.

North American horticultural periodicals.

The periodicals of any subject are supposed to chronicle all the fleeting events of the days and years, and to preserve them for future generations, but it is the most difficult thing to remember and record the journals themselves. Horticultural journals probably have lived and died in this country without having attracted the attention of a single library or collector of books. It is probably no exaggeration to say that more than 500 horticultural journals have been started in North America. There are more than sixty in continuance at the present moment.

The "Massachusetts Agricultural Repository" was started in 1793, but it was as late as 1821 that a horticultural department was added to it. This was an organ of a society rather than a journal in the present sense. American agricultural journalism is usually dated from the establishing of the original "American Farmer" in Baltimore in 1819. The first journal to devote any important extent of its space to horticultural matters was the original "New England Farmer," which was established in Boston in 1822, and which was one of the chief instruments in the organization of the Massachusetts Horticultural Society. Its first editor was Thomas G. Fessenden, author of the "New American Gardener," a book which appeared in 1828, and passed through at least six editions.

A "Floral Magazine" was started in Philadelphia in 1832 and continued sometime afterward. It contained colored plates of ornamental plants. The entire work, except the illustration, was done by the two David Landreths and it was published by them. Tradition says that it was not a paying venture and after several years it was discontinued. The volume of 1832 comprises eighty pages, with descriptions and colored illustrations of thirty-one stove and other ornamental plants. The full title is "The Floral Magazine and Botanical Repository. Published by D. & C. Landreth, Nursery and seedsmen, Philadelphia." The bound volume is 8¾ x 11 inches. The "Horticultural Register and Gardener's Magazine," established in Boston in 1835, and edited by Fessenden and Joseph Breck, and "Hovey's Magazine," were among the first distinct horticultural periodicals. The former, although a magazine of more than ordinary merit, did not persist long. The latter was founded by C. M. Hovey and P. B. Hovey, Jr., and was called the "American Gardener's Magazine and Register of Useful Discoveries and Improvements in Horticultural and Rural Affairs," a journal which, in the third volume, became the "Magazine of Horticulture," and which enjoyed an uninterrupted existence until 1868, thus covering a third of a century of one of the most critical and interesting periods in American horticulture.

The next important journalistic venture was the "Horticulturist," begun in July, 1846, and continued under many changes and vicissitudes for some thirty years, and was finally represented, in line of descent, by "American Gardening," which ceased to exist in November, 1904. The "Horticulturist" had been published in Albany, Rochester, Philadelphia and New York. The first seven volumes were edited by A. J. Downing; the eighth and ninth by Patrick Barry; the tenth by Barry and J. J. Smith; the eleventh to fourteenth by J. J. Smith; fifteenth and sixteenth by Peter B. Mead; seventeenth and eighteenth by Mead and G. E. Woodward. Later it was continued by Henry T. Williams, in New York, until the close of 1875, when the "Horticulturist" was united with the "Gardeners' Monthly," of Philadelphia. This latter magazine started January 1, 1859, as a quarto, but became an octavo with its second volume. It continued until the close of 1887, when, upon the death of its publisher, Charles Marat, it passed into the hands of "American Garden," New York. It had a long and useful career under the editorial management of one of the most accomplished and conscientious of American horticulturists, Thomas Meehan, whom all the succeeding generation had learned to love.

The "American Garden" as such, before it absorbed the "Gardeners' Monthly," traced an independent descent from two other journals. The senior of these was "The Ladies' Floral Cabinet," the first number of which was issued January 1, 1872, by H. T. Williams, who was also editor and publisher of the "Horticulturist," at 5 Beekman Street, New York. Mr. Williams' idea was that the cultivation of flowers properly belonged to women, that they were by nature eminently fitted for it, and that a journal adapted to their wants would greatly aid them in their work, and prove a financial success to the publisher. For some time "The Floral Cabinet" was well sustained and well edited, but after about three years Mr. Williams became wholly absorbed in religious publications and his interest was gradually withdrawn from floriculture. In January, 1880, the "Cabinet" and all the personal effects of Mr. Williams passed into the hands of Adams & Bishop, who continued the publication with varied success, and who intended to close up the business as soon as they could do so to the best advantage. In June, 1882, the paper and good will were sold to Ralph H. Waggoner, who gave it new life; he secured the services of C. L. Allen as an advisory editor, the active work falling upon Miss S. A. Fraser. The last number under Waggoner's management was issued January 1, 1887, when it was absorbed by the "American Garden." The other independent journal absorbed by "American Garden" was known as the "Flower Garden," and the first number was published October 1, 1872; it was edited by C. L. Allen, and published quarterly by C. L. Allen & Co., 76 Fulton Street, Brooklyn, N. Y. It existed one year and was then sold to Beach, Son & Co., seed and bulb merchants, who removed its publication office to Barclay Street, New York, and changed its name to "The American Garden," the late Mrs. C. V. Beach becoming its editor. Beach & Son continued the publication as a quarterly till the year 1880, when B. K. Bliss & Sons secured possession of both the paper and the seed business. It was at this epoch that F. M. Hexamer became editor. Two years later (1882) the publication again became a monthly. In 1883, E. H. Libby secured possession of the property, but its publication was continued under the same editorial control till the end of 1885; during some part of this period the publication office was at Greenfield, Mass. Things stood as they were till 1890, when the magazine shape was adopted. In that year, L. H. Bailey became editor and continued in that capacity till 1893. In January, 1892, soon after the absorption of "Popular Gardening," of Buffalo, N. Y., the title was altered to "American Gardening," so as to unite and typify both names. Prior to this amalgamation, after having had a career of seven years under Elias A. Long, its founder, "Popular Gardening" had absorbed many minor magazines. For a time E. A. Long, in association with T. Greiner, edited the combined journal. After 1893, Leonard Barron assumed the editorship, the periodical having been taken over by the A. T. De La Mare Publishing Company, publishers of "The Florists' Exchange." In October, 1898, James Withers took over the publication. The American Gardening Publishing Company succeeded to the ownership in 1901. In 1903, the American Gardening Co., was organized, the business manager being Thomas B. Meehan; and with this organization the regular continuity of the periodical as a general horticultural magazine came to a close. The "Fruit Grower" of St. Joseph, Mo., took over the mailing list.

The "Philadelphia Florist" completed its first volume in 1852–3. The subsequent volumes (at least three) were known as the "Florist and Horticultural Journal." It was a very creditable monthly magazine, with colored plates. An early journal in the new West was Hooper and Elliott's "Western Farmer and Gardener," Cincinnati, September, 1839–45, with plates colored by hand.

The first pomological journal was probably Hoffy's "Orchardist's Companion," a quarterly, established in Philadelphia in 1841, and edited by Dr. Brincklé. It was a pretentious quarto, with colored plates, of which only one volume was issued. This was followed in 1860 by the "North American Pomologist" by Dr. Brincklé, an abler publication than the other. Other early horticultural periodicals were "Western Horticultural Review," Cincinnati, 1851–3, edited by John A. Warder; "American Journal of Horticulture," later known as "Tilton's Journal of Horticulture," Boston, 1867–71 (9 vols.), edited in its last three years by the younger Robert Manning; "Western Pomologist," Des Moines, Iowa, and Leavenworth, Kansas, 1870–72, by Mark Miller, J. Stayman, and others. The first attempt to establish a weekly, after the pattern of the great English journals, was "Garden and Forest," which appeared in New York in 1888, under the management of Professor Charles S. Sargent, of Harvard University. This journal continued till the close of 1897, comprising ten completed volumes of very high character and entitled to rank as one of the noteworthy undertakings in the entire field (see *Stiles*, p. 1597). Probably the first journal devoted to a particular fruit or plant was Husmann's "Grape Culturist," St. Louis, 1869–71.

The first florists' trade paper to persist is "The American Florist," issued August 15, 1885; this was followed by "Florists' Exchange," in 1889; and "Florists' Review," 1895. "Horticulture," established 1904, is also practically a trade paper. All of these are continuing.

On the Pacific coast, the earliest distinct horticultural periodical was the "California Culturist," the first number of which appeared in January, 1859. This ran through four volumes, and it records the marvels of the first era of modern fruit-growing upon the Pacific slope. Before this, however, "The California Farmer," had been established (January, 1854). It maintained a spasmodic existence for a number of years, and printed the first pomological and horticultural reports of committees. "The Pacific Rural Press" was established in 1871, in San Francisco, and still continues, devoted very largely to the horticultural interests. The "California Horticulturist" was established in 1870, and ran through ten yearly volumes, when, in 1880, it was merged into "The Pacific Rural Press." "The Rural Californian," of Los Angeles, still in existence, was established in 1877. "The California Fruit-Grower," commenced in 1888, still survives (1912) as "The California Fruit News." "The California Florist," first issued in Santa Barbara, then in San Francisco, began in May, 1888, and stopped in 1889. "The California Cultivator," of Los Angeles, established in 1884, is still published. See pages 1507, 1508 for further discussion of California journals.

EXTANT HORTICULTURAL JOURNALS

(With Date of Establishment)

IN CANADA

British Columbia Fruit and Farm Magazine. John Nelson, ed. M. 1909. Vancouver, B. C.

The Canadian Florist. H. B. Cowan, ed. Pub. by Horticultural Publishing Company. Every second Friday. $1. 1903. Peterboro, Ont.

The Canadian Horticulturist. H. B. Cowan, ed. Pub. by Horticultural Publishing Company. M. $1. 1878. Peterboro, Ont.

Fruit Grower and Farmer. James A. Livingston. S.-M. $1. 1907. Grimsby, Ont. (Formerly "Fruit Grower, Market Gardener and Poultryman.")

Le Journal d'Agriculture et d'Horticulture. Pub. by Minister of Agriculture of Quebec. H. Nagant, ed. M. $1. 1879. Quebec, Que.

Manitoba Horticulturist. Published by Manitoba Horticultural and Forestry Associations. M. $1. 1914. Winnipeg.

Maritime Apple. 1912. Kentville, N. S.

IN THE UNITED STATES

Acker und Gartenbauzeitung. The Herold Company. W. $1. 1869. Milwaukee, Wis.

American Florist. The American Florist Company, ed. and pub. W. $1. (Canadian subscription, $2.) 1885. Chicago, Ill.

American Fruit and Nut Journal. H. Harold Hume. S-Q. $1. 1904. Petersburg, Va.

American Fruits. R. T. Olcott. M. $1.50. 1903. Rochester, N. Y.

American Nut Journal. R. T. Olcott. M. $1.25. 1914. Rochester, N. Y.

American Pomologist. Pub. by American Pomological Society. Q. 45 cts.

Apple World, The. U. G. Border. M. $1. 1914. Baltimore. Md. Official organ of the Apple Advertisers of America.

Arkansas Fruits and Farms. E. N. Hopkins. Fort Smith, Ark. (First appeared under title "Ozark Produce Journal," then "Ozark Fruits and Farms.")

Better Fruit. E. H. Shepard. M. $1. 1906. Hood River, Ore.

California Cultivator. C. B. Messenger, ed. W. $1. 1884. Los Angeles.

California Fruit News. H. C. Rowley, ed. and pub. W. $3. 1888. San Francisco. (Formerly "California Fruit Grower.")

California Garden. Alfred D. Robinson, ed. M. $1. 1908. San Diego, Calif.

Carolina Fruit and Trucker's Journal. Z. W. & W. S. Whitehead. S-M. $1. 1897. Wilmington, N. C.

Eastern Fruit. S. M. Paschall. M. 50 cts. 1912. Philadelphia.

Farm and Orchard. R. W. Thrush, ed. M. $1 for 3 yrs. 1913. Keyser, W. Va.

Florida Grower. Florida Grower Publishing Company. W. $1.50. 1908. Tampa, Fla.

Florists' Exchange, The. A. T. De La Mare Printing and Publishing Co. W. $1. 1888. New York.

Florists' Review. H. B. Howard, ed. W. $1. 1897. Chicago, Ill.

Fruit and Produce Distributor. Distributor Publishing Co. W. $2. 1913. Portland, Ore.

Fruit Belt. Geo. W. Welsh. M. 50 cts. 1905. Grand Rapids, Mich.

Fruitman and Gardener. L. McCutcheon, ed. and pub. M. 50 cts. 1897. Mount Vernon, Iowa.

Fruitman's Guide. Fruitman's Guide, Inc. W. $1. 1896. New York.

Fruit Grower and Farmer. W. G. Campbell, ed. M. $1. 1897. St. Joseph, Mo. (Known as "Western Fruit Grower" until October, 1912.)

Fruit Trade Journal and Produce Record. Fruit Trade Journal Company. W. $1. 1889. New York.

Gardeners' Chronicle of America, The. Chronicle Press, Inc. M. $1.50. 1905. Madison, N. J.

Gardening. The Gardening Company, ed. and pub. S-M. $2. 1892. Chicago, Ill.

Garden Magazine. Doubleday, Page & Co. M. $1.50. 1905. Garden City, N. Y.

Green's Fruit Grower. Chas. A. Green, ed. M. 50 cts. 1881. Rochester, N. Y.

Gulf Coast Citrus Fruit Grower and Southern Nurseryman. Albert S. Leecraft. M. $1. December, 1910. Houston, Texas.

Horticulture. W. J. Stewart. W. $1. 1904. Boston.

House and Garden. McBride, Nast & Co. M. $3. 1901. New York, N. Y.

Illinois Horticulture. Pub. by Illinois State Horticultural Society. Q. 1913. Normal.

Intermountain Fruit Journal and Intensive Agriculturist. R. E. Turpin, ed. Alfred Patek, pub. $1. 1910. Grand Junction and Denver, Colo. (Now consolidated with "Western Farm Life.")

Landscape Architecture. Official organ of the American Society of Landscape Architects. Published by Lay, Hubbard and Wheelright. Q. $2. 1910. New York.

Market Growers' Journal. S. W. Severance. S.-M. $1. 1907, Louisville, Ky.

Michigan Horticulture. Pub. by Michigan State Horticultural Society. M.

Minnesota Horticulturist. Minnesota State Horticultural Society. M. $1. 1894. Minneapolis, Minn.

Modern Gladiolus Grower, The. Madison Cooper, ed. and pub. M. 50 cts. 1914. Calcium, N. Y.

National Nurseryman. National Nurseryman Publishing Co., Inc. M. $1. 1893. Rochester, N. Y.

Nebraska Horticulture. Published by Nebraska State Horticultural Society. M. $1. 1911. Lincoln.

Northern Fruit Grower. M. 1911. Howard Lake, Minn.

Northwest Farm and Orchard. R. E. White. M. 50 cts. Spokane, Wash.

Northwest Horticulturist and Dairyman. C. A. Tonneson, ed. and pub. M. 50 cts. 1888. Tacoma, Wash.

Nut-Grower. J. F. Wilson. M. $1. 1902. Waycross, Ga.

Orchard and Farm Irrigation. A. Dixon. M. $1. 1886. San Francisco, Calif. (Formerly "Orchard and Farm.")

Pacific Fruit World. M. V. Hartranft. W. $2. 1895. Los Angeles, Calif.

Pacific Garden. P. D. Barnhart, ed. M. $1. 1907. Pasadena, Calif.

Park and Cemetery and Landscape Gardening. Allied Arts Publishing Co. M. $2. 1891. Chicago, Ill.

Park's Floral Magazine. Geo. W. Park. M. 10 cts. 1871. La Park, Pa.

Peach Growers' Journal and Apple Trade Review. W. John Hinchey, ed. and pub. M. $1. 1899. Middleport, N. Y.

Southern Fruit Grower, The. R. S. Walker, ed. M. 50 cts. 1896. Chattanooga, Tenn.

Southern Orchards and Farms. J. W. Canada. M. 50 cts. 1907. Houston, Texas. (First appeared under title "Texas Fruits." From 1909–11 had the title "Southern Orchard and Homes.") Now appears under title "Southland Farmer," La Porte, Texas.

Tree Gold. Benjamin W. Douglass, ed. M. 50 cts. 1914. Indianapolis, Ind.

Trucker and Farmer. H. J. Hill, ed. M. $1. 1906. New Orleans, La. (Now "Modern Farming." A. B. Gilmore, ed. Established 1870.)

Truck Farmer of Texas. J. C. Loving. M. $1. 1899. Dallas.

Vegetable Grower. H. L. Freking, ed. M. 50 cts. 1911. Spencer, Ind.

Wisconsin Horticulture. Pub. by the Wisconsin State Horticultural Society. M. 1910. Madison.

EXTINCT HORTICULTURAL JOURNALS

IN CANADA

Acadian Orchardist. H. G. Harris, ed. and pub. W. $1. 1873. Kentville, N. S.

Courier and Okanagan Orchardist. Geo. C. Rose, ed. and pub. W. $1.50. 1904. Kelowna, B. C.

Farm and Garden Culturist. Richard Burke, ed. 1888–9. P. E. I.

Bowditch's American Florist and Farmer. M. 1881–5. Boston. (Merged into "Orchard and Garden.")

Cactus Journal. M. 1894–8. Baltimore, Md.

California Culturist. M. 1858–63. San Francisco.

California Florist and Gardener. E. E. Smith, ed. M. 1888–9. San Francisco. (Merged into "Pacific Rural Press.")

California Fruit Exporter. Scott & Wood. M. $1. 1891. San Francisco.

California Horticulturist. M. 1871–80. (Merged into "Pacific Rural Press.")

Central States Fruit Grower. 1896–9. (Later "National Fruit Grower.")

Citrograph. Redlands, Calif.

Colorado Fruit Grower. Paonia and Grand Junction, Colo. (Title changed to "Irrigation Fruit Grower.")

Cranberry Grower. W. H. Fitch, ed. M. $1. 1903–5. Cranmoor, Wis.

Dahlia News. New England Dahlia Society. M. $1. 1907–11. Boston.

Eastern New York Horticulturist. Q. 1897–9. Chatham, N. Y.

Eastern Shore Farmer and Fruit Culturist. M. 1893–1902. Salisbury, Md., and Georgetown, Del. (Established in 1893 as the "Strawberry Culturist.")

Fancy Fruit. Granville Lowther, ed. and pub. M. $1. 1907–9. North Yakima, Wash. (Later changed to "Washington Fruit Grower.")

Farmer and Fruit Grower. Florida Publishing Co. W. Jacksonville, Fla.

Farm, Garden and Poultry. Farm, Garden and Poultry Company. M. 50 cts. 1902. Hammonton, N. J.

Field, Lawn and Garden. W. B. Davis, ed. M. 1874–5. Madison, Wis.

Floral Instructor. M. 1880–91. Ainsworth, Iowa.

Floral Life. Young & Bennett Co. M. 50 cts. 1903–8. Springfield, Ohio. (Merged into "Household Journal and Floral Life.")

Floral Magazine. John Lewis Childs. Floral Park, N. Y.

Florist and Horticultural Journal. H. C. Hanson. M. 1852–5. Philadelphia. (Established as "Philadelphia Florist and Horticultural Journal.")

Flower Garden, The. 1872–4. Brooklyn, N. Y.

Flowers, F. W. Stack, ed. Pub. by Suburban Press. M. $1. 1912. New York.

Fruit and Grape Grower. A. R. Blakey, ed. M. $1. 1886–9. Charlotteville, Va.

Fruit and Vegetable Grower. M. 1889–90. Cheswold, Del.

Fruit Grower. W. $2. 1892. Macon, Ga.

Fruit Grower and Horticulturist. E. R. McKenny, ed. M. $1. 1890–1. Lacon, Ill.

Fruit Grower's Journal. O. O. Buck, ed. and pub. W. from 1883–6.; S.-M. from 1887–1907; M. 1908. 50 cts. 1883. Pub. at Cobden, Ill., 1883–1907; at Treynor, Iowa. 1908. (Merged into "Green's Fruit Grower.")

Fruit Recorder and Cottage Gardener. A M. Purdy. M. $1. 1869–86. Palmyra, N. Y. (Established as "Small Fruit Recorder and Cottage Gardener." Absorbed by "Popular Gardening.")

Fruits and Flowers. D. H. Stearns, pub. M. $2. 1891–2. Portland, Ore.

Fruits and Flowers. A. W. Dyer. M. 10 cts. 1906. Chautauqua, N. Y. (Absorbed by the "Vegetable Grower.")

Garden and Forest. C. S. Sargent. W. $4. 1888–97. New York, N. Y.

Gardeners' Magazine. Joseph Breck. 1835. Boston.

Gardeners' Magazine. M. 1854–5. Boston.

Gardeners' Monthly. Thomas Meehan. M. January 8, 1859 to January, 1888. Philadelphia. (Absorbed by "American Garden.")

Grape Culturist. Geo. Husmann. M. 1869–71. St. Louis, Mo.

Home and Flowers. M. 1896–1904. Springfield, Ohio. (Established as "How to Grow Flowers." Continued under following title.)

Home and Flowers, formerly "How to Grow Flowers," consolidated with "Success with Flowers." M. 1890–1906. West Grove, Pa. (Established as "Success with Flowers." Merged into "Vick's Magazine.")

Home Florist. Q. 1898–1901. Springfield, Ohio. (Merged into "Home and Flowers.")

Horticultural Art Journal. T. B. Jenkins, ed. $2. 1886–91. Rochester, N. Y.

Horticultural Marketplace. John S. Gallagher. W. September, 1910, to October 31, 1910. Rochester, N. Y.

Horticultural Register. Thomas G. Fessenden. M. 1835–9. Boston.

Horticultural Review and Botanical Magazine. J. A. Warder, ed. M. 1853–4. Cincinnati, Ohio. (Established as "Western Horticultural Reveiw.")

Horticultural Visitor. (See "Our Horticultural Visitor.")

Horticulturist. A. J. Downing and others. M. 1846–75. Albany, Rochester, Philadelphia and New York. (United with "Gardeners' Monthly.")

Household Journal and Floral Life. W. A. Martin, ed. M. 25 cts. 1903. Central Publishing Company, Springfield, Ohio.

Hovey's Magazine of Horticulture. C. M. Hovey. M. 1835–68. Boston. Seems never to have had this title on title page. Title: 1835–6, "American Gardeners' Magazine and Register of Useful Arts;" 1837–68, "The Magazine of Horticulture, Botany and all Useful Discoveries and Improvements in Rural Affairs." United with "American Journal of Horticulture" to form "Tilton's Journal of Horticulture.").

How to Grow Flowers. 1896–1900. (Title changed to "Home and Flowers.")

International Horticulturist. 1889. Harrisburg, Pa.

Iowa Horticulture. Pub. by State Horticultural Society. M. Des Moines. January to December, 1908.

Irrigation Fruit Grower. R. H. Perry, ed. M. $1. 1905–11. Denver, Colo. (Established as "Western Slope Fruit Grower;" then as "Colorado Fruit Grower." Absorbed by "Intermountain Fruit Journal.")

Ladies Floral Cabinet. M. 1872 to January 7, 1887. New York. (United with "American Garden.")

Ladies Horticultural Magazine and Floral Register. M. Baltimore, Md. (Prospectus issued in June, 1833.)

Lewiston Orchards Life. H. H. S. Rowell, ed. M. 50 cts. 1912–14. Lewiston, Idaho.

Magazine of Gardening and Botany. M. 1834. Baltimore, Md.

Magazine of Horticulture, Botany and All Useful Discoveries and Improvements in Rural Affairs. (See "Hovey's Magazine of Horticulture.")

The Market Garden. Market Garden Publishing Company. M. 50 cts. First number published in January, 1894, and in July and in October the regular monthly journal began. Discontinued 1906. Minneapolis, Minn.

Mayflower. J. L. Childs. M. 50 cts. 1885–1906. Pub. at Floral, N. Y. 1885–6; Queens, N. Y. 1887–8; Floral Park, N. Y. 1889–1906. (Merged in "Floral Life.")

Meehan's Garden Bulletin. S. M. Meehan. M. $1. 1909–13. Germantown, Pa.

Meehan's Monthly. T. Meehan. M. $2. 1891–1902. Germantown, Pa.

Michigan Fruit Grower. Pub. by Practical Farmer Company. W. 1893–9. Grand Rapids, Mich. 1893–6 "Practical Farmer and Fruit-Grower."

Michigan Horticulturist. Chas. W. Garfield, ed. W. H. Burt Publishing Company, pub. M. 1885–6. Detroit, Mich. (Title changed to "American Horticulturist.")

Missouri and Arkansas Farmer and Fruitman. R. J. Profitt. M. 50 cts. 1888. Kansas City, Mo. (From 1888–94 had title "Kansas City Progress and Western Farm Journal.")

Montana Fruit Grower. 1896–1901. Missoula.

National Fruit Grower. Fruit Grower Publishing Company. M. 50 cts. 1894–1910. St. Joseph, Mo. (From 1896–9 had title "Central States Fruit Grower.")

National Fruit Grower. Chas. Greening. Monroe, Mich. (1896–9 "Central States Fruit-Grower.")

National Horticulturist. Q. 1890–3. Cambridge, Md.

National Horticulturist. National Horticulturist Company. M. $1. 1909 to March, 1912. Council Bluffs, Iowa.

Nebraska Horticulturist. J. G. Carpenter. Q. 25 cts. 1883–93. Blower, Neb.

New England Florist. New England Florist Company. W. 1896–9. Boston. (Established as "Boston Flower Market and New England Florist.")

New York Horticultural Review. 1855. New York.

North American Horticulturist. M. 50 cts. 1895–1907. Monroe, Mich.

Orange Belt. L. M. Holt. M. $2. 1890–4. Pub. at Alessandro, Calif. 1890–2; Rialto, 1893; Los Angeles, 1894. A weekly edition began in 1893 as "The Orange Grower."

Orchard and Garden. J. T. Lovett Company, pub. M. 50 cts. 1879–92. Little Silver, N. J.

Orchard Fruits. Wm. Dyke. M. 50 cts. 1892–3. Effingham, Ill.

Orchardists' Companion. A. Hoffy. Q. 1841–2. Philadelphia.

Ornamental and Forest Tree Grower. J. J. Pinney. M. 50 cts. Evergreen, Wis.

Our Horticultural Visitor. C. G. Mendenhall, ed. M. 50 cts. 1895–1906. Kinmundy, Ill. (First number had title, "Southern Illinois Horticultural Visitor"; 1895–1901, "Horticultural Visitor.")

Pacific Tree and Vine. 1882. San José, Calif.

Peach Grower. Mr. Bryan, ed. and pub. Savannah, Ga.

Peach Grower, Fruit Culturist and Truckers' Magazine. R. M. Martin, ed. and pub. M. 50 cts. 1903–1909. Savannah, Ga.

Philadelphia Florist and Horticulturist Journal. R. R. Scott, ed. 1852–3. (Continued as "Florist and Horticultural Journal.")

Pilot Point Horticulturist. M. Pilot Point, Texas.

Popular Gardening and Fruit Growing. Elias A. Long. M. 1885–91. Buffalo, N. Y. (Combined with "American Garden.")

Practical Farmer and Fruit-Grower. (See "Michigan Fruit Grower.")

Practical Fruit Grower. G. A. Atwood. M. 1894–1907. Springfield, Mo. (From 1894–1900 had title, "The Southwest." Merged into "American Fruit and Nut Journal.")

Practical Nurseryman and Horticultural Advertiser. M. 1893–1902. Huntsville, Ala.

Progressive Eastern Fruit Grower. John S. Gallagher. 1910-11. Rochester, N. Y.

Purdy's Fruit Recorder and Evaporator. A. W. Purdy. Q. 25 cts. 1889–94. Palmyra, N. Y.

Rogue River Fruit Grower. Charles Meserve. M. $1. 1909-12. Medford, Ore.

Rose Journal. Published by the American Rose Society. Q. 1912–13. Fishkill-on-Hudson, N. Y.

Science and Horticulture. C. R. Orcutt. M. $2. Orcutt, Calif. Also pub. at Los Angeles and San Diego.

Seed Time and Harvest. Isaac F. Tillinghast. M. (1880–2, Q.) 25 cts. 1880–94. La Plume, Pa. (Merged in "American Farmer and Farm News.")

Seed Time and Harvest. W. 1897–8. Scranton, Pa.

Seed Time and Harvest. M. 1905–8. Scranton, Pa.

Small Fruit Recorder and Cottage Gardener. 1869–71. (Later "Fruit Recorder and Cottage Gardener.")

Smith's Small Fruit Farmer. B. F. Smith. Q. 50 cts. 1891–4. Lawrence, Kans. (Later "American Horticulturist).

Southern California Horticulturist. Southern California Horticultural Society. M. 1877–9. Los Angeles. (Followed by "Semi-Tropic California;" then united with "Rural Californian.")

Southern Floral Magazine. Morton & Titus. M. 50 cts. Clarksville, Tenn.

Southern Florist and Gardener. M. 1894–9. Louisville, Ky. 1894–7; Chattanooga, Tenn., 1898–9.

Southern Fruit Journal. James Harrison, ed. and pub. M 50 cts. 1904. Montezuma, Ga.

Southern Horticultural Journal. S-M. 1888–91. Denison, Texas.

Southern Horticulturist. H. A. Swasey, ed. M. 1869–70. Canton, Miss., January and February, 1869; Yazoo City, Miss., March, 1869, to August, 1870; Tangipahoa, La., October to Dec., 1870. (Continued as "Swasey's Southern Gardener.")

Southern Horticulturist. M. 1892. Humboldt, Tenn.

Southern Horticulturist. M. Denison and Ft. Worth, Texas.

Southern Illinois Horticultural Visitor. (See "Our Horticultural Visitor.")

Strawberry. R. M. Kellogg Company. M. $1. 1906–7. Three Rivers, Mich. (Merged into "Fruitman and Gardener.")

Strawberry Culturist. (Changed to "Eastern Shore Farmer and Fruit Culturist.")

Strawberry Specialist. O. W. Blacknall. M. 50 cts. 1897–1903. Kittrell, N. C.

Success with Flowers. Dingee & Conard Co. M. 25 cts. 1890 to June, 1904. West Grove, Pa. (Combined with "Home and Flowers.")

Swasey's Southern Gardener. H. A. Swasey, ed. M. 187[illegible]. Tangipahoa, La. (Established as "Southern Horticulturist.")

Texas Fruits, Nuts, Berries and Flowers. (Now "Southern Orchards and Farms.")

Tilton's Journal of Horticulture and Florists' Companion. 1867–71. Boston. (Formerly "American Journal of Horticulture and Florists' Companion.")

Trade Journal and International Horticulturist. M. New York, N. Y.

Tri-state Farmer and Gardener. Tri-state Publishing Company. M. 50 cts. 1895–1907. Chattanooga, Tenn.

Vick's Magazine. Vick's Magazine Company. M. 50 cts. 1878–1906. Rochester, N. Y. Has also been pub. at Dansville, N. Y., and Chicago.

Vineyardist. J. H. Butler. S-M. $1. 1886–1903. Penn Yan, N. Y.

Washington Fruit Grower. E. L. Rorrey, ed. 1907–10. North Yakima, Wash. (Originally pub. under title, "Fancy Fruit.")

Western Farmer and Gardener. Hooper & Elliott. 1839–45. Cincinnati, Ohio.

Western Garden. C. N. Page. 1890–6. M. Des Moines, Iowa. (Is now published as "Poultry Success.")

Western Garden. 1893–4. Denver, Colo.

Western Horticultural Review. J. A. Warder, ed. M. 1850–3. Cincinnati, Ohio. (Continued as "Horticultural Review and Botanical Magazine.")

Western New York Apple. L. P. McNeeley. M. $1.50. 1908. Barker, N. Y.

Western Pomologist. Mark Miller, Dr. Stayman and others. 1870–2. Des Moines, Iowa, and Leavenworth, Kans. (Combined with "The Horticulturist.")

Western Slope Fruit Grower. Paonia, Colo. (See "Irrigation Fruit Grower.").

Wisconsin Horticulturist. Pub. by Wisconsin State Horticultural Society. M. 1896–1903. From 1896–1902 pub. at Baraboo and Madison; 1903 at Sparta and Madison.

Woodsman. Geo. W. Caldwell. M. 50 cts. Evergreen, Wis.

HORTICULTURISTS, NORTH AMERICAN. At this place are brought together brief biographical statements on persons not now living who have been eminent in horticulture in any of its branches in the United States and Canada. It is intended to include those who, by their own efforts, have had marked influence of a national scope, or at least an influence extending beyond state or provincial boundaries, in developing horticultural thought and practice as cultivators, tradesmen, authors, teachers, experimenters. As there is no standard list of such persons, or no recognized basis of judgment, so the present account is undoubtedly incomplete, and it may lack in uniformity. No doubt many other names should have been included; but the present list represents a large correspondence extending over nearly three years, and it is as extensive as circumstances will permit. It is particularly to be understood that this set of biographies does not attempt to constitute any standard by which the merits of individual horticulturists are to be judged. It does not represent an editorial judgment of persons who should finally be included in such lists, but only a collection of data of interest and value so far as it goes. There is need of a standard biographical work on American men and women who have been eminent and prominent in the development of agriculture in its widest sense; it is hoped that these biographies, and those contained in the fourth volume of the "Cyclopedia of American Agriculture," will be of service to editors who come finally to prepare such a work.

Adlum, John (Fig. 1868), grape experimenter, and author of "Memoir on the Cultivation of the Vine," 1823 and 1828, the first separately published American grape book, was born in York, Pa., April 29, 1759, and died at Georgetown, D. C., March 1, 1836. He was a soldier in the Revolution, major in the provisional army in the administration of the elder Adams, and later a brigadier-general in the militia of Pennsylvania. He was also a surveyor and civil engineer. He also held an associate judgeship in Lycoming County, Pennsylvania, having been appointed by Governor Mifflin. He was a friend of Priestly, and endeavored to apply the scientific knowledge of his time to agriculture. He early became interested in the amelioration of the native grapes, and established an experimental vineyard in the District of Columbia. He endeavored, but without success, to secure the use of certain public land in Washington for the purpose of "cultivating an experimental farm." He brought the Catawba grape to public notice. He was a pioneer in the awakening industrial activity of the new country. The botanist, Rafinesque, commemorated his name in the pretty genus Adlumia; but otherwise he has remained practically unknown until very recently. For further information, see Bailey, "Evolution of our Native Fruits." L. H. B.

1868. John Adlum.

Allen, Charles Linnæus, seedsman, florist and author, was born in Union Springs, New York, in 1828 and died at Floral Park, Long Island, May 21, 1909. He early evinced a love for flowers, especially the tree peony and gladioli when they were considered novelties in this country, and he soon made a horticultural and business specialty of these. At this time he lived in Brooklyn, New York, and was a communicant of Plymouth Church. He was superintendent of the Sunday-school for a number of years when Henry Ward Beecher was pastor of the church. Mr. Allen's pleasing ways and love for the children made him well fitted for the work. He was genial by nature, a pleasing conversationalist and a clever writer, an entertaining speaker, and devout churchman. In the early seventies he engaged in the wholesale seed trade at Queens, Long Island, under the firm name of C. L. Allen & Co., and erected an extensive plant for that day and time. The industry did not flourish as he had expected, and the seed business was sold to Hallock & Thorpe, a firm well known to the trade for many years. Mr. Allen then removed to Garden City, Long Island, and engaged to grow flower and vegetable seed by contract for many of the seedsmen, and it is here that he gained an international reputation as a scientific specialist on the culture of cabbage and cauliflower. His fame as a seedsman became worldwide. He wrote several books on horticultural subjects that were pleasing and practical and therefore popular. He spent his last years at Floral Park, New York, and was in great demand as a public speaker for horticultural organizations.

Mr. Allen possessed one of the finest private horticultural libraries in this country, many of the volumes of European origin and of rare merit, some tracing back to Holland and to 1497. Mr. Allen was a scholar and a linguist, and enjoyed the wealth of horticultural literature to the fullest extent. He was widely appreciated for his wisdom, geniality and his comradeship.

G. B. Brackett.

Ames, Frederick Lothrop, of the fourth generation of a family distinguished in the history of Massachusetts enterprise, was born in North Easton, in that state, June 8, 1835, and died September 13, 1893. He was graduated from Harvard College in the class of 1854, and devoted his life to the management of great commercial and industrial interests. Business did not occupy all his attention; he was a Fellow of Harvard College, a trustee of the Massachusetts Society for Promoting Agriculture, and of the Museum of Fine Arts; and an active and faithful director of charitable and benevolent institutions. A munificent patron of arts and sciences, he was successful in stimulating the increase of knowledge in many fields of human research. Devoted through his whole life to horticulture, he gained distinction for his wide and accurate knowledge of tropical orchids and their cultivation, and his collection of these plants at his country place in his native town was the most complete in the New World. His important services to botany and horticulture are commemorated in *Lælia Amesiana*, *Lælia anceps* var. *Amesiana*, *Phalænopsis F. L. Ames*, *Cypripedium Amesianum*, *Cypripedium insigne* var. *Amesianum*, *Vanda Amesiana*, *Stanhopea Amesiana*, *Miltonia vexillaria* var. *Amesiana*, *Odontoglossum Rossiæ* var. *Amesiana*, and *Cattleya Hardyana* var. *Amesiana*.

C. S. Sargent.

Appleseed, Johnny, an interesting and eccentric character, who sowed apple seeds in the wilds of Ohio and Indiana between 1801 and 1847. His real name was Jonathan Chapman. He was born in Boston in 1775, and died in 1847. For forty-six years he walked barefoot through the wilderness, and was never harmed by snakes, wild animals, or Indians. He was often clad in a coffee-sack, in which he made holes for the arms and legs. He would never kill any creature, and considered pruning and grafting wicked. Swedenborg and the New Testament he read aloud in many frontier log cabins. He had many peculiarities, but was always welcomed and respected everywhere. In the war of

1812 he saved many lives by warning the settlers of Hull's surrender and the approach of the Indians. He lived to see trees bearing fruit over a territory of 100,000 sq. mi. The story of this self-sacrificing and useful man is told by W. D. Haley in Harper's, 43:830–836 (1871). A movement is on foot in Ohio to erect a monument to Johnny Appleseed. His history has been the subject of a romance, "The Quest of John Chapman," by Newell Dwight Hillis, 1904. Wilhelm Miller.

Arnold, Charles, nurseryman and hybridist, was born in Bedfordshire, England, in 1818. In 1833 he removed to Paris, Ontario, and in 1853 established the Paris Nurseries. He was elected one of the first directors of the Fruit Growers' Association of Ontario and continued in office during the remainder of his life. He was an enthusiastic hybridist. Of his productions of grapes we note five varieties described in the Bushberg Catalogue for 1883, viz., Othello, Cornucopia, Autochon, Brant and Canada. In raspberries, he raised quite a number of crosses of Antwerp with a whitecap of high quality. Of his many apple seedlings, one especially has proved of standard value, viz., the Ontario, a cross of Spy with Wagener. In crossbred peas, he was very successful, one deserving especial notice, viz., Bliss American Wonder, a cross of Champion of England with Tom Thumb. For this he received from Messrs. Bliss & Son of New York, the handsome sum of $2,000. His death occurred in 1883. Linus Woolverton.

Avery, Robert, pioneer nurseryman, was born in 1796 and died December 30, 1879. He was the first nurseryman and orchardist in the state of Iowa, and in 1837 founded the largest nursery in the state. He himself planted and encouraged others to plant large numbers of fruit trees throughout the Mississippi Valley states.

Bancroft, George, the famous American historian (1800–1891), deserves remembrance among horticulturists for his notable collection of roses at his summer home in Newport, Rhode Island, an account of which may be found in the "American Garden," 1891. For a portrait and sketch, see "Appleton's Annual Cyclopedia" for 1890. In Bancroft's garden, George Field found a rose without a name, which is now known to be the French variety Mme. Ferdinand Jamin. It was introduced by Field & Brothers as the American Beauty.

Barry, Patrick (Fig. 1869), nurseryman, editor and author, was born near Belfast, Ireland, in May, 1816, and died in Rochester, New York, June 23, 1890. He came to America at the age of twenty, and after four years of service with the Princes, at Flushing, on Long Island, he founded in 1840, with George Ellwanger, at Rochester, New York, the Mount Hope Nurseries. Ellwanger and Barry introduced fruit-growing into western New York at a time when there were no collections of fruits, no railroad or telegraphic facilities, nor any fast ocean steamers to bring over their importations from Europe. From 1844 to 1852, Barry edited "The Genesee Farmer," an excellent and influential paper—afterward merged in "The Cultivator and Country Gentleman." After the death of A. J. Downing he succeeded to the editorship of "The Horticulturist," which he removed to Rochester, until June, 1855, after which this famous magazine had many vicissitudes until 1887, when it went to swell the number of periodicals now represented commercially by "American Gardening." In 1851 appeared his "Treatise on the Fruit-Garden," a new and thoroughly revised edition of which was issued in 1872, under the title of "Barry's Fruit-Garden." It is still one of our most popular books on pomology, and deservedly so. The catalogue of fruits which he compiled for the American Pomological Society is a monumental work. Mr. Barry did much to make Rochester a city of nurseries and western New York a famous fruit-growing region. The Western New York Horticultural Society, of which he was president for more than thirty years, and until his death, has long exercised a more than sectional influence. The work of Barry was truly national, and essentially that of a pioneer. He must be considered in the front rank of pomological authors, with the Downings, Warder, and Thomas, whose combined weight gave a great impulse toward establishing orcharding on a large scale in America. For a fuller account, see "Annals of Horticulture," 1890, 287–290.

Wilhelm Miller.

1869. Patrick Barry.

Bartram, John, called by Linnæus the greatest natural botanist in the world, was born at Marple, near Darby, Pennsylvania, March 23, 1699, and died September 22, 1777. He was a Quaker farmer, who became interested in botany after the age of twenty-four. In 1728, at Kingsessing, on the Schuylkill River, he established the first botanic garden in America (page 348, Vol. I), which, together with his house, built in 1731 of stone hewn by his own hands, is preserved as part of the park system of Philadelphia (Fig. 1851). He traveled much in America, and was for many years the chief medium of exchange between Europe and America of plants of all kinds, especially new and important species, as *Rhododendron maximum* and *Cypripedium acaule*. His correspondence with Peter Collinson lasted nearly half a century. The letters, preserved to us in Darlington's "Memorials of John Bartram and Humphrey Marshall," are rich in botanical, historical and general interest. "Observations on the Inhabitants . . . made by John Bartram in his Travels from Pensilvania to Onondago, Oswego, and the Lake Ontario . . . London, 1751," is similarly readable, and a document of great value in the study of aboriginal races.

At the age of seventy he undertook, with his son William, an expedition to Florida, which is recorded in the "Journal Kept upon a Journey from St. Augustine up the River St. Johns." Bartram was probably the first American to perform successful experiments in hybridization. His sons, John and William, continued his garden. For many years it was the largest and best collection of trees and shrubs in America, and the services of the garden to early American horticulture were very great. He is commemorated in Bartramia, a genus of mosses, and in "Bartram's Oak," for the literature of which see I. C. Martinale's "Notes on the Bartram Oak, *Quercus heterophylla*, Michx.," published at Camden, New Jersey, 1880. Bartram's garden is a unique spot in America. Many of the trees have attained great age, size and beauty. The garden also contains many quaint and picturesque relics which have associations of great interest. On the whole, John Bartram is one of the most illustrious, and by far the most picturesque, of the early botanists and horticulturists of America, and his simple, wholesome, powerful personality presents a picture that is altogether amiable. New editions of the works of Bartram and Darlington are much to be desired, and offer a promising field to critical labors. John Bartram's son William is well known to students of American history for his "Observations on the Creek and Cherokee Indians, 1789." It is very much to be regretted that no authentic portrait of John Bartram is known. For an excellent illustrated account of Bartram and his garden, see article by Miss M. L. Dock in "Garden and Forest," 9:121–124 (1895). See also "Harper's Magazine," 60:321–330 (1880). Wilhelm Miller.

Beadle, Delos W., scholar, horticulturist, writer, was the son of Dr. Beadle, St. Catharines, Ontario, one of the pioneer nurseryman of the province. He was graduated in Arts at Yale University in July, 1844, and two years later was granted B. A. (*ad cundem*) by the University of Toronto. In 1847, the degree of LL.B. was conferred upon him by Harvard University, and in 1848 he was called to the bar in New York City, where he practised law for about six years. In 1854, he was admitted to an interest in his father's business, and in this line he became widely known throughout Canada. In addition to his other business, Mr. Beadle accepted the position of horticultural editor of "The Canada Farmer," and in 1861, two years after its first organization in Hamilton, he was made secretary and treasurer of the Fruit Growers Association of Ontario, and himself contributed largely to its wonderful growth and usefulness, continuing to be its most important officer until his retirement in 1887. As a writer on horticultural and pomological subjects, Mr. Beadle occupies an important place, as shown by his numerous contributions to the reports of the above-mentioned society and to the "Canadian Horticulturist." Of this latter journal, he was practically the originator in 1878, and continued to edit it until 1887. In November, 1862, he was made corresponding member of the Entomological Society of Philadelphia, and in 1865 a corresponding member of the Horticultural Society of London, England. In 1872, Mr. Beadle published his "Fruit, Flower and Kitchen Gardener," and as late as the year 1903 contributed his final article to the "Canadian Horticulturist" entitled, "The Carnivorous Plants of Canada." He died in Toronto, Ontario, August 30, 1905. Linus Woolverton.

Berckmans, Prosper Julius (Fig. 1870), scholar, horticulturist, nurseryman, and botanist, was born in Arschot, Belgium, October 13, 1830, and died at Fruitland Nurseries, near Augusta, Georgia, November 8, 1910. His boyhood was spent upon the estates of his father, who was himself a horticulturist of some note. He secured his elementary education at Liers and Tourney; in 1845 he went to France, attending school at Saint Germain and graduating from Tours in 1847. While at Saint Germain, he took lectures on botany at the Jardin des Plantes in Paris, and whenever possible attended the meetings of the Royal Horticultural Society of France. In 1847 he returned to Belgium and spent three years overlooking the parental estates and studying botany at the Botanical Gardens of Brussels. It was during this period that he became acquainted with Bivort and other prominent European horticulturists.

For political and religious reasons, young Berckmans left Belgium for the United States in 1850; in 1851 he was joined by his family who soon thereafter purchased a farm near Plainfield, New Jersey. It was during his six years residence here that he first met Charles Downing and others prominent in American horticulture. In the fall of 1857, Mr. Berckmans moved to Augusta, Georgia, and established the Fruitland Nurseries by purchasing a one-half interest in the nurseries of D. Redmond. The following year, 1853, he bought the other half interest and started in business alone with about twenty-five acres of nursery stock. From that time until his retirement in 1907, Mr. Berckmans' sole object was the advancement and upbuilding of southern horticulture; and as a reward for his work the University of Georgia conferred the degree of Master of Science upon him in 1880.

Mr. Berckmans spent the major part of his life in an untiring effort to originate, introduce and disseminate fruits and ornamentals of value to the South. Plants, cuttings and seed were imported from all parts of the world to be tested at Fruitlands, and the nurseries became not only an experimental station but a botanical garden as well, from which disseminated many of the most valuable plants of the southern horticulturist, among which are the Honey and Peen-to peaches, Kelsey plum, Japanese persimmon, hardy lemon or *Citrus trifoliata* (Poncirus), Amoor River privet, *Biota aurea nana* (Thuja), besides other fruits and ornamentals.

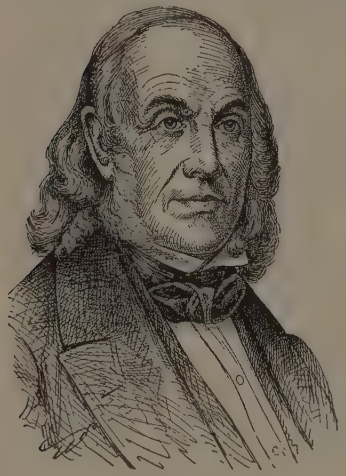
1870. P. J. Berckmans.

The society affiliations of Mr. Berckmans were numerous and in their volumes of proceedings are found most of his writings. In 1869 he first took an active part in the Americal Pomological Society and served on various important committees until 1887 when he was elected president, which office he held until resigning in 1897. He founded the Georgia State Horticultural Society in 1876 and was its president from that time until his death in 1910. The Massachusetts Horticultural Society made him a corresponding member; he was likewise honored by La Societé D'Horticulture et D'Histoire Naturelle de L'Hérault de Montpellier, France; La Societé Pomologique de France, La Societé D'Horticulture de la Gironde de Bordeaux, and La Societé D'Horticulture du Department du Gard, France. His position as president of the State Horticultural Society of Georgia made him a member of the State Board of Entomology, on which board he served from its foundation until his death. He was also a member of the Board of Control of the Georgia Experiment Station when it was organized, but served only a few years. In 1883–4 he went to Europe for the United States Government, to collect horticultural exhibits for the New Orleans Exposition. He was presiding officer over the Horticultural Congress in Chicago in 1893; Chairman of the Jury of Award at the Jamestown Exposition in 1907; and the only American representative to judge the fruit at the centennial of La Royale Societé d'Agriculture et de Botanique de Gand, at Ghent, in 1908. T. H. McHatton.

Brackett, George C., nurseryman, was born at Unity, Maine, October 26, 1830, and died at Fresno, California, April 18, 1903. In his early years, his family moved to Cincinnati, Ohio, and later to Denmark, Iowa, where his father commenced the nursery business. It was here that George became interested in horticulture. He was a graduate of Amherst College. In 1856, he went to Leavenworth, Kansas, and joined the army. He was in a law partnership from 1857 to 1859 and, after the dissolving of this partnership, he bought land near Leavenworth and opened up a nursery and fruit farm. This was the first nursery established in Kansas. Mr. Brackett was the first to introduce the cultivation of the strawberry and the first to grow pears in Douglas County. He was a charter member of the Kansas State Horticultural Society and its secretary for twenty-six years; also secretary of the American Pomological Society 1891 to 1898. For portrait, see "Trans. Kansas Horticultural Society," Vol. XXVII, p. 8.

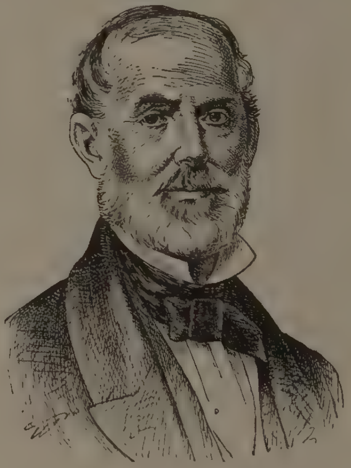
Breck, Joseph, 1794–1873 (Fig. 1871), Boston seedsman, and author of "The Flower Garden, or Breck's Book of Flowers," first published in 1851, and reissued in 1866 as the "New Book of Flowers." This was preceded, in 1833, by "The Young Florist." In 1822, he founded the seed business now conducted at 51 North Market Street, under the name of Joseph Breck & Sons. He was one of the original members of the Massachusetts Horticultural Society, and its president from 1859 to 1862. He edited the old "New England Farmer" for many years, but discontinued it in 1846, when he turned over his list of subscribers to Luther Tucker, of Albany, New York, at the time of the founding of "The Horticulturist," which was edited by the illustrious A. J. Downing. He also edited "The Horticultural Register" from 1836 to 1838, in company with Thomas Fessenden. The revision of his book in 1866 was undertaken when the author was seventy years old. It was a popular book in its day. Wilhelm Miller.

Bridgeman, Thomas (Fig. 1872), gardener, florist, seedsman and author, was born in Berkshire, England, and came to America in 1824, and established the business which is now conducted under the name of his son, Alfred Bridgeman, at 37 East Nineteenth Street, New York. An historical account of this business may be found in the catalogue of the present firm. In 1829, Thomas Bridgeman published "The Young Gardener's Assistant," which was many times reprinted and eventually enlarged to five times its original bulk. It was copyrighted in 1847, when it appeared as a large-sized work in three parts, covering fruit, vegetable, and ornamental gardening. Two of these parts were published separately in the same year as "The Kitchen Gardener's Instructor," and "The Florist's Guide." The first-named work was revised by Sereno Edwards Todd, and republished in 1866 by Alfred Bridgeman. Thomas Bridgeman died in 1850. Wilhelm Miller.



1871. Joseph Breck.

1872. Thomas Bridgeman.



1873. William Brincklé.

Brincklé, William Draper (Fig. 1873), physician and amateur pomologist, was born in Delaware. He began the practice of medicine at Wilmington in 1820, moved to Philadelphia in 1825, where he passed most of his life as a busy physician, and died at Groveville, New Jersey, in 1863, at the age of sixty-four. In a room of his Philadelphia home he hybridized strawberries, and had fruit at every season of the year. He also had a little garden about the size of a parlor. He produced the Cushing strawberry, the Wilder, President Cope, Cushing, and Orange raspberries, and the Wilmington and Catherine Gardette pears. Unfortunately, most of his work with raspberries was done with *Rubus Idæus*, the Old World species, which is not hardy in America, but his yellow-fruited variety of raspberry is still regarded by many as the acme of quality. He was for many years vice-president of the Pennsylvania Horticultural Society, and was regarded as a leader of American pomology. In raising pear seedlings, he was wont to graft and regraft annually, after the second or third year from seed. He thus produced new fruits in half the time required by Van Mons, many of whose novelties did not fruit within twenty years from seed. Dr. Brincklé gave away thousands of grafts to amateurs and tradesmen everywhere, and always prepaid the carriage. In 1860 he edited "Hoffy's North American Pomologist," a high-class periodical with colored plates, which, unfortunately, did not survive. Some sprightly anecdotes of Dr. Brincklé are reprinted from the "Gardener's Monthly" for 1863, in Bailey's "Evolution of Our Native Fruits." Wilhelm Miller.

Brown, Jacob G., pomologist, was born in Lewisburg, Pennsylvania, April 26, 1825, and died near Wyoming, Delaware, November 17, 1896. He came to Delaware in March, 1868, and purchased a farm of about 200 acres in central Kent County. He immediately planted a peach orchard of 2,700 trees. In 1870 he set another peach orchard and 200 apple trees. In 1872 he set about 20 acres in apples, another 20 acres in peaches, and commenced growing small-fruits, especially red raspberries, increasing until he had 50 acres of red raspberries, and in 1885 nearly the whole farm of 200 acres was set in fruit, 100 acres of it in apples. He planted nearly every variety of apples that he could find described in the catalogues of nurserymen. Mr. Brown made a close study of fruit-growing and carried on the business with a great deal of energy. He became a member of the Peninsula Horticultural Society soon after its organization in 1888, and took great delight in talking about his fruit-growing. He was especially enthusiastic about apple-culture. He was one of the pioneers in apple-growing in Delaware and became more sanguine of its great success year by year until his death in 1896. Mr. Brown took an active interest in every movement that was planned to develop fruit-growing, and was a public-spirited citizen.

Wesley Webb.

Bruner, Thomas Kincaid, was born in Salisbury, North Carolina, on January 17, 1855, and died in Raleigh in February, 1908. For many years his father was editor and owner of the "Salisbury Watchman." Young Bruner, who received his education at Finley's Academic School in Lenoir, North Carolina, early entered his father's office. His intelligence, industry, and initiative united to induce him to study nature and nature's works, along with his daily duties, and led him to be a reader and a thinker. In 1886 he was selected as secretary of the State Board of Agriculture, and thereafter he lived in Raleigh. His services as secretary were varied. He had devoted especial attention to the study of geology, crystalography, and arboriculture. In his new field he collected for the state and for various expositions specimens of ores, crystals, woods and other natural products that attracted attention wherever they were displayed. He was in charge of the state exhibits at Atlanta, Georgia, at Boston, at Omaha, at Chicago, at St. Louis, and in Paris. He was a member of the International Jury of Awards at New Orleans as representative for the Bulgarian government. He edited and wrote many articles on the resources of his native state. Mr. Bruner's interests were wide and his mental activities covered many subjects. Few men ever rendered more service to the agricultural and industrial life of their states. D. H. HILL.

Bryant, Arthur, pioneer nurseryman of Illinois, was born near Princeton, Illinois, on October 15, 1834, and died May 13, 1907. Early in life, he became interested in the nursery business as an aid to his father and later as owner of the business. Mr. Bryant was one of the founders of the Northwestern Fruit Growers' Association and at one time its president. He was also president of the Illinois State Horticultural Society and of the Northern Illinois Horticultural Society for a time.

Budd, Joseph Lancaster, horticulturist, investigator and educator, was born near Peekskill, New York, July 3, 1835 and died at Phœnix, Arizona, December 20, 1904. In 1859, he started in the nursery business at Wheaton, Illinois, and a few years later removed to Shellsburg, Iowa, where he established the Benton County Nurseries. He was successful as a nurseryman and fruit-grower, but in 1876, he accepted the professorship of horticulture and forestry at the Iowa Agricultural College where he remained for nearly twenty-two years. Professor Budd was instrumental in the importation of hardy trees, shrubs and fruits from Europe, especially from Russia, which he visited in 1882, with Charles Gibb, for this purpose. He also improved many native fruits, foremost amongst which was the plum. Professor Budd was the author of the "American Horticultural Manual." For a fuller account and portrait, see "Cyclopedia of American Agriculture," Vol. IV, p. 558.

Buist, Robert, florist, seedsman, and author, was born at Cupar Fyfe, near Edinburgh, Scotland, November 14, 1805, and died in Philadelphia, July 13, 1880. He was trained at the Edinburgh Botanic Gardens, came to America in August, 1828, and was employed for a time by Henry Pratt. In 1830 he became the partner of Hibbert, who had established the first notable florist's business in Philadelphia. He became noted for his successes with roses, which were at that time second in popular favor to the camellia with the Philadelphians. The great improvement of the verbena was largely due to him, and was immediately followed by the introduction into America of a distinct class of bedding plants. He introduced *Poinsettia pulcherrima* to the trade, and his sale of the double form is said to have been the first transaction of the kind accomplished by ocean telegraph. He was the author of "The American Flower-Garden Directory," in 1832, "The Rose Manual," 1844, and "The Family Kitchen-Gardener" (copyrighted, 1847), all of which were frequently reissued, and enjoyed a considerable sale for many years. An excellent account of his life may be found in "The Gardener's Monthly," 22:372 (1888). The frontispiece of the bound volume for the year is his portrait. WILHELM MILLER.

Bull, Ephraim W., the introducer of the Concord grape, lived a long, quiet, and useful life in Concord, Massachusetts, where he died September 27, 1895, in his ninetieth year. In commercial importance, the greatest event in the early history of American grapes was the introduction, early in the fifties, of this variety of the northern fox-grape. The first fruit of this grape was obtained in 1849. Its exact origin is obscure. In 1840, Mr. Bull bought the house in which he lived until his death. That year some boys brought from the river some wild grapes, and scattered them about the place. A seedling appeared from which Mr. Bull obtained a bunch of fruits in 1843. He planted seeds of this bunch, and a resulting plant fruited in 1849. This variety was named the Concord. It soon became the dominant grape in all eastern America, as it was the first variety of sufficient hardiness to carry the culture of the vine into every garden in the land. It is a pregnant type, and has given rise to no less than fifty honorable seedlings, which range in color from greenish white to purple-black. The quality of the fruit is excelled by many varieties, but the latter usually demand more careful cultivation. The Concord is the one most important type of American grape, and the really successful commercial viticulture of the country dates from its dissemination; and yet this grape is apparently only twice removed from the wild vine. (See Fig. 1709.) For portrait, see Bailey, "Evolution Native Fruits."

Ephraim W. Bull was loved of his neighbors and honored by every countryman who grows or eats a grape. He made very little money from his variety, and died in extreme poverty. The original vine is still preserved, as a sprout from the old root. L. H. B.

Burnet, Robert, minister and horticulturist, was born at Lady Kirk, Berwickshire, Scotland, 1823; died at Hamilton, Ontario, 1889. After his ordination, he volunteered as a missionary to Ontario, then Upper Canada. For twenty-six years, he was minister to St. Andrew's church, Hamilton, Ontario, during which time he took a very active interest in horticulture. His large garden was to him both a pleasure and a study and contained a very large and choice collection of varieties of dwarf pears and other fruits. From these, he gained many valuable notes for use at meetings of the provincial fruit growers' association. In the year 1869, Mr. Burnet was elected president of this association, an office which he filled with great credit for ten successive years. His annual addresses formed an important feature in the annual reports made to the Department of Agriculture for Ontario during those years. The reports also contain several prize essays by him, as for example in 1875 one on "The Cultivation of the Pear," and one on "Where and How to Market our Fruits;" also in 1876 an excellent paper entitled "Criteria for Fruit Judging."

LINUS WOOLVERTON.

Burr, Fearing, seedsman and author, was born in 1815 and died suddenly at his home in Boston, Massachusetts, October 4, 1897. He gained his horticultural experience in early life on the broad acres of the paternal homestead. This experience, added to his inherent tastes and his copartnership in the firm M. &. F. Burr, Seedsmen, Boston, gave him creditable notice as a prominent horticulturist throughout New England and the distant states and territories. His firm was among the early ones which exchanged international courtesies with seedsmen. In 1865 he published "The Field and Garden Vegetables of America." This was a very interesting and erudite contribution to horticulture at that day, and the book found ready sale. He was an author of some note and contributed to the horticultural columns of the press. He was elected a life member of the Massachusetts Horticultural Society in 1852 and did much excellent work for the society in the matter of judging fruits and vegetables, and making creditable exhibits. In 1857 his firm was awarded a silver medal for its display of "Sixty Varieties of Beans, all neatly and correctly labelled." He was diligent in business, a fluent conversationalist, a ready writer, an earnest lecturer and a man whose judgment and advice on horticultural topics was earnestly sought.

G. B. Brackett.

Bush, Isador, nurseryman and pioneer grape-grower, was born in 1822 at Prague, Bohemia. He died in the city of St. Louis, Missouri, August 5, 1898, having been a resident there for more than fifty years. In 1865, he established a grape nursery at the place he named Bushburg, Missouri, and devoted himself to the cultivation of this specialty with marked enthusiasm and success. He soon had a collection of all known species and varieties of our native grapes and with the assistance of the eminent botanist, George Engelmann, a very complete classification of various species was made and their characteristics were fully described in his valuable publication, the "Bushburg Catalogue and Grape Manual." It was through the enterprise of Mr. Bush that our immune grape roots were sent to Europe for the purpose of grafting the vinifera varieties upon them, and thus the ravages of phylloxera were prevented. The American grape industry owes a debt of lasting gratitude to the pioneer work of Mr. Bush.

G. B. Brackett.

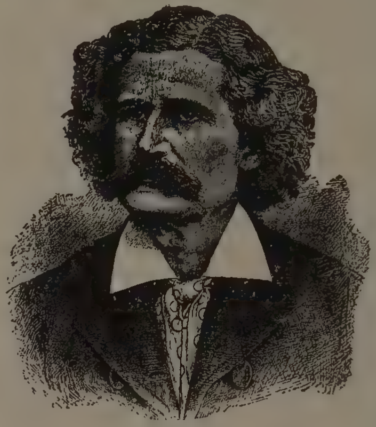
Butz, George C., horticulturist and educator, was born at New Castle, Pennsylvania, on February 1, 1863, of Swiss parentage, and died December 14, 1907. He was prepared for college at the New Castle High School and graduated from Pennsylvania State College in 1883. The following year he became an instructor in the preparatory department of the college; in 1887 he was elected to the position of assistant professor of horticulture, and in 1903 he was made professor of horticulture. During many years, he was also a lecturer at the farmers' institutes of the state, nursery inspector and adviser for the State Department of Agriculture, and horticulturist of the State Experiment Station. He is the author of a number of valuable bulletins and other publications upon subjects relating to his life work. A natural love for plants from his boyhood made Professor Butz an apt pupil and determined his life work. He was an authority on horticultural subjects. His opinion on the culture of grapes, peaches, ginseng and carnations was much sought after by state authorities, and his writings upon these subjects were highly valued.

Intellectually Professor Butz was a man of culture and broad horizon. His mental operations were painstaking, methodical, exact. Notwithstanding his lifelong practical experience in horticulture, he was a careful student of its rapidly developing literature and brought to his work the combined products of observation and wide reading. Always devoted to duty, cheerfully making the best of adverse conditions, spending himself unstintedly for the welfare of his college and of his state, his life of high ideals and unselfish service was an inspiration to all who knew him.

R. L. Watts.

Campbell, George Washington, horticulturist, was born in Cortland County, New York, January 12, 1817, and died at Delaware, Ohio, August, 1898. He is best known as the introducer of the Delaware grape. He originated and improved numerous other varieties of grapes, among which are Campbell's Early and Lady. For a fuller account, see "Cyclopedia of American Agriculture," Vol. IV, p. 560.

Carman, Elbert S. (Fig. 1874), agricultural editor and experimenter, was born on Long Island in 1836 and died in 1901. He was educated at Brown University and after graduating was in business for a number of years. Always interested in gardening and fruit-growing, he finally associated with the late Andrew S. Fuller in conducting the "Rural New Yorker." A little later Mr. Carman bought the paper and established in connection with it the Rural Experiment Grounds in New Jersey. Here he tested with great care the varieties of farm and garden seeds offered by seedsmen. At that time, the ordinary seed catalogue was filled with gross exaggeration in text and illustration. Mr. Carman's accurate reports were largely instrumental in starting a genuine reform in catalogue-making. Later he spent much time at hybridizing and selecting new varieties of potatoes, grains and flowers. His most notable achievement in this line was the famous family of Carman potatoes, including the Rural New Yorker No. 2. At one time, it is probable that there were more of this variety grown than of any other known sort. In the markets today, the larger number of round, thick potatoes are known and sold as "Rurals." As a farm journalist, Mr. Carman was very successful, giving power and individual character to his paper. He wrote one book "The New Potato Culture" in which he recorded his exhaustive experiments with fertilizers, preparation of seed and methods of culture.



1874. Elbert S. Carman.

H. W. Collingwood.

Carr, Robert, was born in the parish of St. Andrews, County of Downs, in the north of Ireland, in 1767. He was but eight years old when he was brought to Philadelphia. In later years, William Bartram, proprietor of the celebrated Bartram Gardens became his friend, and later his father-in-law. At the death of Mr. Bartram, Mr. Carr continued the business of the Gardens, which were the cradle of botany and horticulture on the American continent. The Gardens gave these sciences a distinguished position in the literature of the old world, and they were also the pride of every Philadelphian for a great many years. At the formation of the first society of horticulture in 1827, Colonel Carr was a charter member, and in 1834 he was made its vice-president, a position he held until the time of his death, which occurred in 1866.

G. B. Brackett.

Cobbett, William (1762–1835), the once-famous English author, had two periods of enforced residence in America, and wrote "The American Gardener," which is one of the spiciest books in the whole history of American horticulture. He was of thorough Saxon ancestry, and while a gardener's lad and during eight years of military service, made strenuous efforts at self-education. In 1792 his personal liberty was endangered by the publication of "The Soldier's Friend" (an appeal for an increase of pay), and he came to Philadelphia in the autumn of that year. His first success was a pamphlet entitled, "Observations on Dr. Priestly's Emigration," a bitter attack on the French Revolution. He took the loyalist side in American politics, and is regarded as the founder of the American party press. His attack on Benjamin Rush, the leading physician of Philadelphia, for his advocacy of unlimited bleeding for yellow-fever, resulted in a libel suit, and damages of $5,000, which nearly ruined Cobbett, and sent him to England in June, 1800. In 1802 he began "Cobbett's Weekly Political Register," which he edited for thirty-three years, and until his death, except during an interval of imprisonment and a second withdrawal to America. His real work was domestic reform, and the circulation and influence of his journal were immense. He wrote extensively and entertainingly on a wide variety of subjects. As historical documents, his works are indispensable.

Cobbett's horticultural writings of chief interest to us are "Cottage Economy," "A Year's Residence in the United States of America," and, most of all "The American Gardener" (1821), which was reproduced with considerable modifications as "The English Gardener," in London, 1827. The American edition of Wm. Forsyth's excellent "Treatise on the Culture and Management of Fruit Trees," was published at New York and Philadelphia in 1802, and in Albany in 1803, and was one of the most influential books on fruit-growing in the period before orcharding over large areas gave rise to essentially American horticultural writings.

Wilhelm Miller.

Cole, Samuel W., nurseryman, author and editor, was born in the town of Cornish, Maine, in 1796, and died at Chelsea, Massachusetts, December 3, 1851. At about the age of twenty he left his native state and passed two or three years in New Jersey and Pennsylvania in teaching. Soon after his return he published the "Columbian Spelling Book," a collection of poems called "The Muse," and in 1835, the "Yankee Farmer;" the latter he removed to Portland, Maine, and continued there about three years, in connection with a seedstore and agricultural warehouse. In 1839 he came to Boston and continued connected with the agricultural press to the time of his death and was editor of the "New England Farmer" during the years 1849, 1850 and 1851. Mr. Cole published the "American Fruit Book" in 1849, and a book on "Diseases of Domestic Animals," which have passed through several editions. He also established and carried on the Winnisimmet Nurseries in Chelsea, Massachusetts, during the years from 1840 to 1850.

Wm. P. Rich.

Coleman, Norman J., lawyer, agricultural journalist, first Secretary of Agriculture, and horticulturist, was born near Richfield Springs, New York, May 16, 1827, and died in St. Louis, Missouri, November 3, 1911. He was granted the degree of Bachelor of Law from the University of Louisville (Kentucky), and for some years was a practising attorney at New Albany, Indiana, and later in St. Louis. With an intense love of rural pursuits, he gave up his lucrative law practice, purchased a country home near St. Louis, and began the publication of "The Missouri Valley Farmer," now known as "Coleman's Rural World," one of the pioneer agricultural papers of the Mississippi Valley. He was Lieutenant-Governor of Missouri, 1874 to 1878; served as a member of the Board of Curators of the Missouri State University for sixteen years and was, for a number of years, a member of the Missouri State Board of Agriculture. He was Secretary of Agriculture during the administration of President Cleveland, being the first to hold this position after its creation as a cabinet office. Through the "Rural World" he issued a call for "a meeting for the purpose of advancing and directing the fruit-growing interests of Missouri and the West." As a result, on January 5, 1859, "The Missouri Fruit Growers' Association," since 1868 known as the "Missouri State Horticultural Society," was organized. Mr. Coleman was the first president of this organization and served in this capacity for periods aggregating nearly a decade. This is the oldest, permanent fruit-growers' organization west of the Mississippi and its annual reports, covering a period of more than half a century, are an important adjunct to the literature of the horticultural development of the section. In his official positions, Mr. Coleman's energies were largely devoted to the organization of horticultural interests. His horticultural writings occur mainly in the Reports of the Missouri State Horticultural Society and in the columns of "The Rural World."

J. C. Whitten.

Conard, Alfred Fellenberg, nurseryman and original president of The Conard & Jones Co., of West Grove, Pennsylvania, was born in Philadelphia, in 1835, and died December 15, 1906. He was descended from German Quakers, who joined William Penn's Colony in 1683. His early life was spent on his father's farm near West Grove, where later he learned the nursery business under the personal supervision of Thomas M. Harvey. Soon after 1862, with Charles Dingee, he established a nursery business under the firm name of Dingee & Conard. This prospered, and about 1869, the firm turned its attention to the propagation of roses by a new process introduced by Antoine Wintzer, an expert Alsatian propagator. This was a success so far as the production of roses was concerned, but the wholesale demand at that time was small and the problem soon presented itself of how to market their rapidly increasing stock. With rare foresight Mr. Conard conceived the idea of disposing of it at retail through the mails.

The company issued at first a very modest catalogue. It was skilfully prepared, and offered bedding plants, shrubbery, bulbs, seeds, and the like, in addition to their attractive list of roses. This, accompanied by wise advertising, brought in orders quite satisfactorily, and strictly fair and honorable treatment of customers, good healthy stock and careful packing soon established for the company an enviable reputation, and their trade extended to all parts of the world.

About the year 1892, Mr. Conard and Mr. Wintzer having previously become separated from the Dingee & Conard Co., associated themselves with S. Morris Jones, and organized the Conard & Jones Co., for the purpose of continuing the growing and distribution of roses, flowering plants, and the like. As a specialty, they took up the improvement of the canna.

Mr. Conard was a man of very retiring nature, and for this reason was not so prominent in the trade generally as his long experience and extensive knowledge of the floral business would have warranted. He was scholarly in his tastes, methodical and precise in his habits, well read and well informed. He was particularly proficient as a mail-order salesman, and was the first advertiser in any line of business to contract with advertising concerns to place the business on a percentage basis, a plan that has now been almost universally adopted.

Thomas P. Conard.

Coxe, William, pioneer pomologist, was born in Philadelphia, May 3, 1762, and died on his farm on the Delaware River near Burlington, February 25, 1831. He deserves special remembrance for his excellent and now scarce book, "A View of the Cultivation of Fruit Trees, and the Management of Orchards and Cider," with accurate descriptions of the most estimable varieties of native and foreign apples, pears, peaches, plums and cherries cultivated in the Middle States of America. This was printed at Burlington, and published at Philadelphia in 1817. Grapes and small-fruits were not included in the scope of his book, but an article of his in the "American Farmer" for July, 1828, shows that he was acquainted with many varieties of grapes, and had done much grafting. His book was a standard until the time of the Downings, and was freely used by other authors. The illustrations were excellent for their time, but show only the size and outline of a fruit, and whether it was dotted, splashed or streaked. (Fig. 1858.)

Coxe said, 1817, that he had been "for many years actively engaged in the rearing, planting and cultivating fruit trees on a scale more extensive than has been attempted by any other individual of this country." He also had a national reputation for his cider at an age when it was a famous and characteristic beverage.

William Coxe belonged to one of the most refined families of Philadelphia. His early education was somewhat meager by reason of the Revolutionary War, but he became a cultured gentleman. John Jay Smith gives this pleasant picture of him: "Well do we remember his extensive library in his fine mansion on the 'Bank' at Burlington, when as a little boy we were assigned the duty of bringing away, or taking home, some book or pamphlet from his ever open stores of information. . . His person was handsome, and his bearing that of the 'old-fashioned' gentleman, improved by mixing in the best society, but retaining the forms of the greatest politeness and suavity, that modern usages are too rapidly casting off. An errand to Mr. Coxe's was a cherished privilege; never was the opportunity neglected by him to place in the hand of his visitor some fruit that he so well knew would be appreciated by a youthful appetite. The finest Seckel pears we have ever seen were not unfrequent deposits. He had an especial fondness for the Seckel pear, which is certainly among the half-dozen most famous pears of American origin, and which was pronounced by Downing to be the finest flavored of all pears." Coxe was made an honorary member of the Horticultural Society of London for making known the merits of this pear through Dr. Hosack. Either the first willow or the first poplar planted in Burlington is said to have been brought from Halifax in the hand of William Coxe. He planted many trees to beautify the town and, in particular, extended the front of the "Green Bank." Biographical details are unfortunately only too meager. A few other details may be gleaned from the "Horticulturist," 11:304–307 (1856). WILHELM MILLER.

Craig, John (Fig. 1875), horticulturist and educator, was born at Lakefield, Argenteuil County, Quebec, in 1864, and died at Siasconsett, August 10, 1912. He obtained his early education at Montreal High School and McGill College. Early in life he exhibited a taste for horticulture and later studied under one of the greatest pioneer horticultural teachers, J. L. Budd, of the Iowa Agricultural College. Shortly after graduation from this institution in 1887, Professor Craig was appointed horticulturist at the Central Experimental Farm at Ottawa. He was called to Iowa as professor of horticulture in 1899, and in 1900 became professor of extension teaching at Cornell University. In 1903, he was appointed professor of horticulture at this institution, which position he held until his death. During the latter years of his life, Professor Craig took great interest in the development of nut-culture, both for the North and South, and was the recognized authority on many kinds of nuts. He contributed largely to horticultural and agricultural magazines and was the editor of "The National Nurseryman" for several years. Professor Craig was a member of the advisory board of the American Civic League, and chairman of the nomenclature committees of the American Sweet Pea and the American Peony Societies. He was also elected a fellow of the Royal Horticultural Society of Great Britain. He was well known for his interest and work as a pomologist, having been early associated with Charles Gibb (p. 1576), and having followed the subject closely throughout life. In 1903, he was elected secretary of the American Pomological Society, which important position he held until his death. A. C. BEAL.

1875. John Craig.

Curtis, Joseph, pioneer fruit-grower of Illinois, was born in New Jersey, May 29, 1786, and removed with his parents when a boy, to Manchester, Ohio. He had never seen a nursery and had no horticultural experience, but he invented the arts of root-grafting and collar-grafting fruit trees through stern necessity for grafting stock. At the age of sixteen he had secured a piece of land on which to plant an orchard. He had grown some seedling trees but had an insufficient number for the ground he had. As the pieces of roots were plowed up, it occurred to him that he might make more trees by grafting these roots. He succeeded and immediately thereafter invented collar-grafting. He was from 1798 to 1817 collecting and testing twenty-seven varieties of apples in his Ohio orchard. In March, 1818, he built a log-cabin, selected a fine tract of land in what is known as the north arm of Grand Prairie, Edgar County, Illinois, and in 1818 established the first nursery in the state of Illinois and the first orchard of grafted fruit trees planted in Edgar County. He grew such varieties as Yellow Newtown, Smith (Cider), Newtown Spitzenberg, Milam, Priestley, Gilliflower, Rhode Island Greening, Rambo and Winesap. He originated a number of choice varieties of fruits, especially some of our leading varieties of apples. He did more than any other one man of his day to introduce choice fruits into southern Illinois and the adjacent territories. Among his most zealous contemporaries were Edson Harkness of Tivoli, Peoria County, Cyrus Overman, Canton, and Arthur Bryant, Princeton. To such men are due the credit of the organization of the Northwestern Fruit Growers Association in 1851, the first society of its kind west of the Alleghanies, embracing great extent of territory and demanding any great degree of public opinion. And through the united efforts of these men, with others, the Illinois Horticultural Society was organized at Decatur in 1856. G. B. BRACKETT.

Darlington, E. Dillwyn, was born on November 20, 1858, in Doylestown, Pennsylvania, and died March 26, 1908. As a boy he entered a small private school, later the Doylestown Seminary, and finally Swarthmore College at the age of sixteen. Intensive study up to this time had undermined his health to such an extent that after a few months he was obliged to leave school. An inborn desire for activity prompted him to seek and find a position in the office of the Doylestown "Intelligencer." But even this proved too confining so that, after a few weeks, he had to give up and seek occupation outdoors. A natural tendency started him growing plants for local markets. Soon he found out how much had to be learned in this line and he secured a position with the prominent firm of Hoopes, Bro. & Thomas, Nurserymen, of West Chester, Pennsylvania. After serving an apprenticeship of one year, he returned to Doylestown to start seriously in the business of growing plants for sale. This was in 1875. Steadily he grew and developed until in 1883 he became connected with what turned out to be his life's work—the trial-grounds of W. Atlee Burpee & Co., Seedsmen, Philadelphia. Mr. Darlington first conducted these trials on a vacant lot adjoining his property. As the Burpee business grew, the trial-grounds grew, and when, in 1888, a farm was acquired for the purpose of doing this important work, Mr. Darlington logically became superintendent of the new venture.

From that time until his death he served the American public with a keen, observing and analytical mind possessed by few men. For twenty-five years he studied the merits and faults of all sorts of vegetables and flowers. Tens of thousands of trials came under his observation every year. The best of European and American seed-breeders' efforts had to pass his critical decisions, and out of this tremendous "sifting" process rose scores of meritorious varieties of vegetables and flowers, the names of which have since become household words with planters throughout the country.

ADOLPH KRUHM.

Dartt, Edward Harvey Schuler, nurseryman, was born at Weathersfield, Vermont, November 24, 1824, and died at Owatonna, Minnesota, January 31, 1903. At the age of twenty, he moved from Vermont to Ripon, Wisconsin, where he attended college and taught school. About 1860 he moved to Kingston, Wisconsin, and engaged in general merchandising, holding at the same time the offices of postmaster and justice of the peace. In 1869 he removed to Owatonna, Minnesota, where he remained until his death. He engaged at once in the nursery business and continued in it more or less the rest of his life. He was one of the early members of the State Horticultural Society, and in 1889 was made an honorary life member for conspicuous efforts along horticultural lines.

In 1891 the Owatonna Tree Station was established by act of the legislature and Mr. Dartt was made its superintendent and continued in this capacity until his death. He conducted many experiments here and raised thousands of seedlings, contributing much to the horticultural knowledge of the state by his efforts. He was always active in the meetings of the society and much of the early advancement in horticulture in Minnesota is due to Mr. Dartt. He laid out and maintained a public park at his own expense for many years and was always interested in civic improvements in the town. He delighted to write short articles on civic and horticultural affairs for the press and in this way helped to mold public opinion.

LE ROY CADY.

Deane, Rev. Samuel, poet and agricultural writer, was born at Dedham, Massachusetts, July 30, 1733, and died at Falmouth (now Portland), Maine, November 12, 1814, where he had been pastor since October 17, 1764. While vice-president of Bowdoin College, he published, in 1790, his "New England Farmer, or Georgical Dictionary," the first American encyclopedic work on agriculture. This had a much wider circulation, probably, than Jared Eliot's "Essays upon Field-Husbandry," 1747. Its influence may be traced to the middle of the present century. Deane's work was freely quoted by F. G. Fessenden until his death, in 1837. The second edition, 1797, was entitled "The Georgical Dictionary." A third edition was published in 1822.

Deane and Eliot were the chief writers in that early stage of American horticulture when it was hardly important enough to be considered distinct from general agriculture. For biographical details, see Drake's "Dictionary of American Biography."

Dearborn, Henry Alexander Scammell, soldier, statesman and author (1783–1851), was also an ardent horticulturist. He was a moving spirit in the organization of the Massachusetts Horticultural Society, and was elected its first president March 17, 1829. He was partly instrumental in the establishment of an "experimental garden and cemetery at Mount Auburn," the parent of rural cemeteries. The plan of the cemetery was largely his. He "devoted himself to this work most assiduously," writes the chronicler of the society, "spending the greater part of the autumn [1831] at Mount Auburn, in laboring with hands as well as mind, without money and without price." The Abbé Berlese's "Monography of the Camellia" was translated by him, and published in Boston in 1838. He also translated from the French, in 1830, an account of the since famous *Morus multicaulis*. He left MS. writings on horticulture. For notes on his horticultural labors, see "History of the Massachusetts Horticultural Society," 1880, which contains a portrait; also John B. Russel in Tilton's "Journal of Horticulture," 7:88, 157, 276. Gen. H. A. S. Dearborn was son of Gen. Henry Dearborn, of Revolutionary and later fame.

L. H. B.

Dempsey, Peter C., pomologist and hybridist, was of United Empire Loyalist stock and was heir to the orchard and nursery left by his father at Albury, Prince Edward County, Ontario. About the year 1867, Mr. Dempsey decided that he would devote his life to horticulture, and especially to the cultivation of the apple. In 1859, he united with the Fruit Growers' Association of Ontario and being a pleasing and fluent speaker, full of information drawn from practical experience, he soon became a highly valued member and was elected vice-president in 1873 and again in 1875; and president in 1880 and again in 1881. In 1775, he was selected by the Ontario Department of Agriculture to superintend the Ontario fruit-exhibit at the Centennial exhibition in Philadelphia, and secured several medals for its excellence. But it is as a hybridist that Mr. Dempsey is most widely known among horticulturists, having originated among other novelties the Burnet grape, the Dempsey potato and the Trenton apple. His death occurred in August, 1892, at Albury.

LINUS WOOLVERTON.

Dixon, John N., pomologist, was born in Fayette County, Pennsylvania, on February 20, 1821, and died in 1883. When quite young, his parents moved to Ohio, and here at the age of twenty-two, he set out an orchard of 1,100 trees, a large orchard for those days. In 1855 he went to Iowa, expecting to make fruit-growing his specialty, but on account of the cold winters and tender varieties, lost most of his trees. He persisted, however, and in 1868 started the present orchard of 12,000 acres, of which he made a great success. He is said to have been the first man to use insecticides in the form of spray in a commercial way in fruit plantations.

Dorner, Frederick, florist, was born at Schilltach, Baden, Germany, on November 29, 1837. At the age of seventeen he emigrated to this country and joined his brother at Lafayette, Indiana, where he lived until his death, December 29, 1910. In 1870, after being employed at various occupations, he rented a small farm and became a market-gardener. In the small greenhouse on the place, he began raising potted plants for the retail market. In 1888 he became interested in some experiments in the breeding of carnations, which were being conducted at Purdue University. He quickly saw the possibilities of the work and became so deeply interested that he took up this line of work himself. From the first lot of seedlings, raised in 1889 and numbering about 500, came the varieties Christina Dorner, Tecumseh, Hoosier, Mrs. Harrison, Indiana, and Ben Hur. His work continued uninterruptedly for twenty-one years and during this time he grew over 150,000 seedlings. Of this number not more than seventy-five ever reached the market. Among the best of his productions were Mad. Diaz Albertini, Wm. Scott, Mrs. G. M. Bradt, White Cloud, Lady Bountiful, White Perfection, Pink Delight, and White Wonder. Fred Dorner was the first florist in the Middle West to disbud carnations. The method of supporting carnations by means of wires and cross strings also originated with him. His work, however, was not limited to carnations. He was also the originator of a number of good chrysanthemums of which Major Bonnaffon, disseminated in 1894, was the best.

H. B. DORNER.

Douglas, Robert (Fig. 1876), pioneer nurseryman in Illinois, was born at Gateshead, England, in 1813. He came to America in 1836, finally settling at Waukegan, Illinois, in 1844. Here he founded a small nursery where he raised conifer and other tree seedlings. This was the first attempt ever made in America to raise evergreen trees commercially. Through his efforts, many successful plantations of forest trees were established on the western prairies. He has been called "the apostle of tree-planting in the West." Mr. Douglas was also a good botanist and an authority on evergreens. He was an active member of the Illinois State Horticultural Society. He died in 1897.

1876. Robert Douglas.

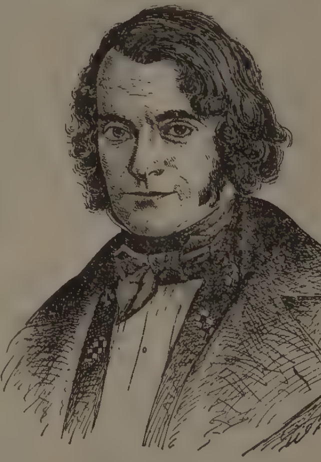
Douglas, Thomas Henry, nurseryman and forester, was born at Waukegan, Illinois, July 31, 1852, and died March 26, 1907. After completing his education at Racine College, he engaged in the nursery business with his father, the late Robert Douglas, whose early experiments and later his success in growing conifers from seed gave him a national reputation. Inheriting the natural qualities of a forester from his father and being a close student of nature, he soon acquired a wide knowledge of forestry which was recognized in 1886 when he was called to the State Board of Forestry of California as Head Forester and soon after was called to a similar position at Leland Stanford, Jr., University. While there he collected many plants then new to California, tested them out and introduced them. In 1892 he visited the home of the weeping spruce (*Picea Breweriana*) on the summit of the Siskiyou Mountains and succeeded in gathering the first seed and raising the first seedlings of this species. He cared little for publicity but was freely consulted on all matters pertaining to forestry, and his articles on this subject are considered an authority. Many of his introductions, notably the Smithiana Douglas, Douglas Pyramid and Douglas Golden arbor-vitæs are well known and widely planted today.

R. Douglas' Sons.

Downer, John S., pomologist and nurseryman, was born June 19, 1809, in Culpeper County, Virginia, and died in Kentucky in 1873. Like the man "born to fame" he seemed to evince a taste for horticulture from his earliest days. While yet a youth, without friends or fortune, he established and gradually built up the Forest Nursery, which gained an enviable reputation not only in Kentucky but in neighboring states. He was patient and painstaking and tested many varieties of fruits under his own inspection. He did much to improve pomology in the Central States. He paid special attention to the strawberry, and produced the well-known Downer (Prolific), (Chas.) Downing and Kentucky. These should perpetuate his fame, for it was at a time when the strawberry industry of the country was in its infancy. He introduced the Wild Goose plum and he conferred the blessings of pomology on the whole country by disseminating many choice varieties of fruit. He was quiet and unobtrusive, but was a man of worth and honesty. His nursery at Elkton, Kentucky, was for many years a fruit experiment station. He was vice-president for Kentucky of the American Pomological Society, and held other offices of trust and honor.

G. B. Brackett.

Downing, Andrew Jackson (Fig. 1877), the first great landscape gardener of America, was born at Newburg, New York, October 30, 1815, and perished by drowning July 28, 1852, at the early age of thirty-seven. As a boy, he was quiet, sensitive, and much alone with himself and nature. The Catskills, the Hudson, and his father's nursery had much to do with his development. His "Treatise on the Theory and Practice of Landscape Gardening," published 1841, when he was but twenty-six years old, is, in many respects, a unique production. It was the first, and is today one of the best American books on the subject, and has exerted a greater influence upon American horticulture, it is said, than any other volume. "Cottage Residences," 1841, also had great popularity. In 1845 appeared simultaneously in London and New York the first edition of "Fruits and Fruit Trees of America;" in 1846 he became connected with "The Horticulturist," which he edited from his home at Newburg until his untimely death. His editorials in this excellent periodical (later represented in succession by "American Gardening") were republished after his death, with a letter to his friends by Frederika Bremer, and a memoir by George William Curtis, under the title of "Rural Essays." It was not until 1850 that he had an opportunity to visit the great estates of England, to see with his own eyes the landscape gardening of Europe. On his return in 1851, he was engaged to lay out the grounds near the Capitol, White House, and Smithsonian Institution at Washington. On July 28, 1852, he left Newburg on the steamer Henry Clay for New York. The Clay took fire near Yonkers, while it was racing, and Downing's life was lost in an attempt to save others. It would be difficult to overestimate the influence of Downing. He created American landscape gardening. His only predecessor, André Parmentier, is little known, and his influence was not of a national character. Downing's quickening influence affected country life in its every aspect. He stood for the simple, natural, and permanent as opposed to the intricate, artificial, and ephemeral. He was the first great American practitioner of what is known in polite and technical literature as the English or natural school of landscape gardening in distinction from all artificial schools, as the Italian and Dutch. Downing's pupils are many, and his spirit still lives. He gave inspiration to Frederick Law Olmsted, our next great genius in landscape gardening, who, by his early work in Central Park, New York, aroused that popular enthusiasm which has culminated in the American idea of great municipal park systems, as opposed to the earlier Old World idea of exclusive pleasure-grounds and private parks. Downing's books have had large sales, and have gone through many editions. His intellectual successor in his purely pomological work was his brother Charles, whose modest labors in the revision of the "Fruits and Fruit Trees of America" have brought him little popular fame, but much sincere admiration from students. Most horticultural writings are, in reality, only records of progress; they do not create progress.

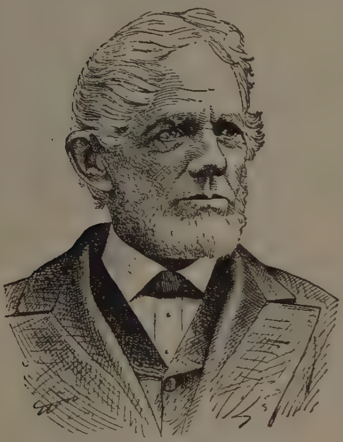


1877. A. J. Downing.

Few of our horticultural books are epoch-making. Downing's writings, however, started a great popular movement in America toward beautiful homes and home grounds. By many persons, Andrew Jackson Downing is considered the greatest single figure in the history of American horticulture, and one of the few persons who can be said to have had real genius. An appreciation of Downing's personality will be found in Frederika Bremer's "Homes of the New World." (See *Downingia*, for the genus of plants named after him).

WILHELM MILLER.

Downing, Charles, (Fig. 1878), distinguished pomologist and elder brother of Andrew Jackson Downing, the landscape gardener, was born at Newburg, New York, July 9, 1802. He was educated at the local academy, and from the age of thirteen to eighteen worked part of the time in his father's nursery. At the age of twenty he started in the nursery business on his own account. From 1834 to 1839 his brother Andrew was a partner in this business. About 1850, he sold out his nursery business and devoted himself to the study of varieties of fruits, on which subject he was the leading authority until his death. The "Fruits and Fruit Trees of America" is the monumental American work on varieties of fruits. The book was projected by Andrew, but the great bulk of the work was done by Charles in continuing and revising it. His test orchard contained trees and grafts of 1,800 varieties of apples, 1,000 pears, and other fruits in proportion. In 1896 a city street was put through it. Charles Downing was very modest and retiring. He would never make a public speech, but he wrote many pomological articles over the signature "C. D." All his work is marked by conscientious accuracy. He died January 18, 1885.



1878. Charles Downing.

WILHELM MILLER.

Dreer, Henry A., seedsman and florist, founder of one of the oldest American horticultural establishments, was born in Philadelphia, August 24, 1818, and died December 22, 1873, at the age of fifty-five. His parents were Frederick Dreer, of Hanover, and Fredericka Augusta Nolthenius, of Grossakenheim, Germany. They were married in America. The Nolthenius family emigrated to the United States in the last decade of the eighteenth century. Henry A. Dreer's education was largely in German, and obtained in Philadelphia. He was fond of gathering seeds and plants in the country, and would bring them home to cultivate. He was trained in his father's business, that of a cabinet-maker. In 1838, at the solicitation of a friend, he began as a seedsman and florist in a small way, at 59 Chestnut Street. In 1863 he moved his store to 714 Chestnut St., where the business has been conducted ever since with the addition of No. 716. His only son, William F. Dreer, succeeded his father and conducts the extensive business in Philadelphia and at Riverton, N. J.

Henry A. Dreer was of modest temperament and frail constitution, and confined himself to business rather closely. He was liberal in public matters, but always kept out of political life. He compiled several small works in connection with the business, and wrote frequently for the "Saturday Evening Post," of Philadelphia, and for Godey's "Ladies' Magazine."

WILHELM MILLER.

Dufour, John James, a Swiss vigneron, was at the head of a colony to grow the wine grape in Kentucky, and the author of "Vine Dresser's Guide," published in Cincinnati in 1826. The Kentucky experiment failed, and the colony then settled in southern Indiana, on the banks of the Ohio River; and this settlement is now the city of Vevay. Here Dufour died in 1827. This Indiana experiment brought out the merits of the Alexander grape, a native, and thereby did much to establish an American viticulture. For detailed account of the Dufours and their associates, and the results of their work, see Bailey, "Evolution of Our Native Fruits."

Eliot, Charles, landscape architect and author, passed away at Brookline, Massachusetts, early in the year of 1897. It is is said that no one of the present generation has shown greater ability in the art of landscape gardening on an extensive scale. From the time of his graduation until the time of his death, all his strength and energy had been given to the improvement of private grounds and public parks. A Harvard graduate, he took a post-graduate course at Bussey Institution, spending much of the time in studying the trees and shrubs in Arnold Arboretum. After familiarizing himself for a time with foreign parks and gardens, he entered the office of the late F. L. Olmsted, as a student. On completing his studies with Mr. Olmsted, he established his office in Boston and soon had a large clientele. He later became a member of the firm of Olmsted, Olmsted & Eliot and soon became identified with national undertakings with which he will long be remembered. While a member of the Appalachian Mountain Club, he was secretary and president of the corporation known as Trustees of Public Reservations, and from this organization sprang the admirable Metropolitan Park System. Mr. Eliot was the first landscape architect appointed by this Commission, and continued so until his death. To him, more than almost any other man, Massachusetts at least, is indebted for the improvement of her large tracts of land.

He was one of the best professional writers of his day on landscape gardening. His style was clear, earnest and convincing, and he allowed no minor matter to stand in the way of what he deemed the broadest and finest treatment, looked at from the future, and no other man during the past few years of Charles Eliot's life did so much toward crystallizing the better interests of the parking systems. To his work he brought vim, a trained intellect, a personal charm and a mature judgment. The public loss was great when Charles Eliot left his work.

G. B. BRACKETT.

Eliot, Jared, author of an early American book on agriculture, was born November 7, 1685, and died April 22, 1763. He was the grandson of John Eliot, the "apostle of the Indians," and was pastor at Killingworth, Connecticut, from October 26, 1709, until his death. He was a botanist, and the leading consulting physician in New England. He introduced the mulberry tree into Connecticut, wrote an essay upon the silkworm, and discovered a process of extracting iron from ferrugineous sands. His "Essays upon Field-Husbandry," begun in 1748, are generally regarded as the first important American book devoted exclusively to agriculture, although not actually the first work on the subject in the New World. It is now extremely rare. He was a high-minded, progressive and useful citizen. Many of his sermons were separately reprinted. Jared Eliot and Samuel Deane were among the few agricultural writers of note in the period before American horticulture was considered distinct from agriculture. See p. 1509; for portrait, "Cyclopedia American Agriculture," Vol. IV, p. 568.

WILHELM MILLER.

Elliot, Wyman, pioneer horticulturist, was born in Corinna, Maine, May 19, 1834, and died in Minneapolis, Minnesota, June 16, 1913. As a boy he helped his father about a grist-mill and on the farm and at odd times helped his mother in the fruit- and flower-garden, where he laid the foundation of his horticultural career. At the age of twenty the family went to Minneapolis, then a town of fifteen or twenty families. They purchased land and Mr. Elliot began raising vegetables and farm products. He was the first market-gardener in Minneapolis. In 1855 he took up a claim near Monticello in Wright County among the Indians, being one of the first farmers to till soil west of the Mississippi. In 1856 he returned to Minneapolis and took charge of the home place. He continued in the market-gardening business here for twenty-five years. He added fruits and ornamental stock to his crops and the place was known as the Minneapolis Garden Nursery for many years. By 1862 Mr. Elliot had built up a good market-gardening business. In 1864 he added a greenhouse and grew flowers and plants for sale. In 1866 a tree nursery was started and for many years supplied Minneapolis with trees, fruits and flowers. Many of the trees he planted will adorn the Minneapolis streets for many years and be a lasting monument to him.

In 1864 he helped organize the Hennepin County Horticultural Society and in 1866 helped organize and was a charter member of the State Horticultural Society. He was several times vice-president of the State Agricultural Society and held some office in the State Horticultural Society from its organization in 1866 until his death, serving as member of the executive committee, president six years, and from 1892 until his death he was chairman of the executive committee. Always of a quiet, unassuming character, he did work of untold value to the horticultural interests of the state.

LE ROY CADY.

Elliott, Franklin Reuben, died at Cleveland, Ohio, February, 1878. To him is due the honor of first suggesting and earnestly advocating the formation of state horticultural societies. He was secretary and a charter member of the Missouri Fruit Growers' Association, 1859; secretary of American Pomological Society, 1867, and a valued officer of the Ohio State Horticultural Society. He was a man of great ability in horticultural matters, and was the author of the "Fruit Book" and a well-known treatise on "Landscape Gardening." He was a valued contributor to the horticultural press at a day when American horticulture most needed advice.

G. B. BRACKETT.

Ellwanger, George, nurseryman, was born in Germany on December 2, 1816. His youth was spent in his father's vineyards where he acquired a love of horticulture and determined to devote his life to it. To this end, he studied horticulture in one of the leading institutions of Stuttgart. He came to the United States in 1835, and in 1839 settled at Rochester, New York. The next year he and Patrick Barry entered into partnership forming the nursery and seed firm, Ellwanger & Barry. Mr. Ellwanger was a member of the American Pomological Society, the Western New York Horticultural Society, and a corresponding member of the Massachusetts Horticultural Society. He died on November 26, 1906.

Emory, Robert Samuel, pomologist, was born April 2, 1832, near Centerville, on the Chester River, Maryland, and died June 2, 1906. His father was a lifelong agriculturist, carrying on that occupation most successfully until his death. Robert when a boy attended the public school, and later spent four years as a student in Dickinson College, Carlisle, Pennsylvania. Afterward he was employed as clerk in a wholesale drugstore in Pittsburgh, studying pharmacy, receiving a diploma, and remaining with the firm until he was twenty-one. He then returned home and engaged in agricultural work. In 1860, he settled near Chestertown, where he began the culture of fruit for market, on a considerable scale. He soon came to be regarded as an authority on all subjects connected with the production of fruit. His orchards comprised extensive plantings of pears and peaches, with a specialty of pears, and probably he raised more of this variety of fruit than any one east of California. In his orchard there were about 20,000 trees in bearing condition. His reputation as a skilful fruit-grower gained for him prominence, and his place on the Chester was the frequent resort of those concerned in fruit-culture from all sections desirous to see for themselves his well-managed orchards, to learn his methods, and to profit by his experience, the results of his own endeavors at individual research. In 1877, he was awarded the first prize for the best twenty-one varieties of pears by the American Pomological Society.

When the San José scale appeared in the East, he was among the first to recognize it as a deadly enemy, but by applying whale-oil soap saved his orchards until other remedies were discovered. All scientists were cordially welcomed to his home and orchards, enjoying the advantage which his experiences could give them. Captain Emory became a member of the Peninsula Horticultural Society a few years after it was organized and served as president during one year.

E. W. EMORY.

Ernst, Andrew H., nurseryman and pomologist, was born in Germany in the year 1796. He was proprietor of one of the earliest established and best nurseries in Ohio. He was a pioneer and champion of pomology in Ohio and the Northwest. Mr. Ernst established Spring Grove Cemetery in Cincinnati, one of the most beautiful cemeteries in the United States. He was vice-president of the American Pomological Society and president of the Ohio Pomological Society from 1847 until his death, which occurred on February 13, 1860.

Evans, James Calvin, one of the pioneer fruit-growers of the Mississippi Valley and for years one of the leading horticulturists of that section, was born in Jackson County, Missouri, April 25, 1833 and died in 1909. He was of a strictly pioneer family in western Missouri, being the son of Wm. B. Evans, who died in 1855, and nephew of the late Col. Milton McGee, so well and honorably known in the annals of Kansas City. In 1861 he acquired an extensive home plantation, in what is now North Kansas City. Being passionately fond of horticulture, he began its adornment and the development of extensive fruit-plantations. At the age of twenty-six he became a charter member of the Missouri Fruit Growers Association, organized in Jefferson City in 1859, its name being changed to the Missouri State Horticultural Society in 1862. This is the oldest permanent horticultural organization west of the Mississippi. He was elected president of this society in 1876 and served efficiently in this capacity for more than twenty years. He was also a charter member of the Missouri Valley Horticultural Society organized in 1868, and served as its president for twenty-three years. He was also a life member of the American Pomological Society and other horticultural bodies, which he has served from time to time as an officer or on important committees. In 1883 he organized the Olden Fruit Company and began planting the famous 1,400-acre orchard at Olden, which was the first extensive commercial orchard in the Ozark region. Due to the success of this enterprise and largely through his advice as to varieties and methods of orchard management found to be best adapted to that section, scores of extensive orchards began to be planted in the Ozarks. On his home plantation at Kansas City as well as at Olden, he maintained large areas for testing the adaptability of varieties of fruits to the western section. He was also ever on the alert to locate promising specimens of wild fruits of the state, especially grapes, raspberries, wild crabs and persimmons. The orchards which he planted still contain (1914) a large collection of these wild fruits, which were in process of amelioration at the time of his death. Among his special contributions to the list of varieties originated in the state may be mentioned the Miller persimmon, Evans peach, Evans raspberry and Evans crab, the latter being a large-fruited form of the native crab *Pyrus ioensis*. It was largely through his assistance and advice that an extensive experiment in breeding apples was inaugurated at the South Missouri Fruit Experiment Station in the nineties. As a result of this work hundreds of varieties, crosses between leading commercial sorts, were originated with the hope that some might combine the more desirable characteristics of both parents. This work is now being conducted by Colonel Evans' oldest son, who is disseminating these new sorts, many of which have much promise in the state. The writings of Colonel Evans consist largely of horticultural papers which have appeared during the past fifty years in the Reports of the Missouri State Horticultural Society. J. C. WHITTEN.

Fessenden, Thomas Green, editor and author, 1771–1837, founded "The New England Farmer" at Boston in 1822, and edited it until his death. The present "New England Farmer" is not the lineal successor of Fessenden's paper. Fessenden is chiefly noted as a satirical poet, and he was more of a literary man than a gardener. He was born at Walpole, New Hampshire, was graduated at Dartmouth College in 1796, and studied law. He went to England in 1803, and there published his humorous poem, the "Terrible Tractoration." He settled in Boston about 1804. In addition to "The New England Farmer," he edited the short-lived "Horticultural Register," and "The Silk Manual." He wrote "The Complete Farmer and Rural Economist," "The New American Gardener," and "The American Kitchen Gardener," three books of a cyclopedic nature designed to cover the fields of agriculture, horticulture and vegetable-gardening respectively. They adhered very closely to the contemporaneous English type of horticultural writing. These books appear to have passed through many editions, but they were little altered from issue to issue. They often seem to lack the enthusiasm of direct contact with growing plants. Fessenden's time was one of general farming, and the viewpoint of gardening was mostly that of the home or amateur. He lived before the days of specialized farming on a large scale, and of commercial horticulture and floriculture. During the greater part of his editorship of "The New England Farmer" there was but one other important American agricultural paper, "The American Farmer," which was published at Baltimore, beginning 1819. The most important contemporaneous American writings on horticulture of a cyclopedic nature were "The American Gardener's Calendar," by Bernard M'Mahon, Philadelphia, 1806, and "The American Gardener" of John Gardiner and David Hepburn, Georgetown, District of Columbia, 1804. For a copy of "The Country Lovers," Fessenden's once famous song to the tune of Yankee Doodle, together with Hawthorne's pen-picture of the man, and an account of his interesting life, see Duyckinck, "Cyclopedia of American Literature," 595–599. WILHELM MILLER.

Fuller, Andrew S. (Fig. 1879), horticultural writer, was born in Utica, New York, on August 3, 1828, and died May 4, 1896, at his home at Ridgewood, New Jersey. At the age of eighteen he went to Milwaukee, Wisconsin, where he worked at the carpenter's trade, and became particularly skilful in the construction of greenhouses, and built a small one for himself on a city lot. Here he brought together a varied collection of plants, the care of which founded the nucleus of his later attainments and renown as a horticulturist. In 1855, he moved to Flushing, Long Island, when William R. Prince offered Mr. Fuller the management of his greenhouses. But his ambition did not allow him to remain long in the employ of others, and in 1857 he removed to Brooklyn, and engaged in grape and small-fruit culture, which were then in their infancy. Here he gave particular attention to the improvement of the strawberry by cross-fertilization and selection of the best of the many thousands of seedlings raised by him. The most famous of these were Brooklyn Scarlet, Monitor and Colonel Ellsworth, the first of which was generally recognized as the highest-flavored strawberry in existence at the time, although too soft for market. The entire stock of 300,000 plants was purchased by the "New York Tribune," which sent them out as premiums to its subscribers, in consequence of which they have been widely known as the "Tribune strawberries." It was during this period that Fuller wrote his first book, the "Strawberry Culturist." Realizing the necessity of having more ground for experimentation, and in order to escape the noise and turmoil of the city, he bought a large piece of land near Ridgewood, New Jersey. This, when he moved on it, early in the sixties, was little more than a barren waste, but it developed into one of the most charming homes and interesting and instructive garden spots in the country. Almost every species and variety of ornamental trees and shrubs hardy in the locality were represented, and his collection of small-fruits was the most complete in the country. Immediately after the publication of the "Strawberry Culturist," he began working on the "Grape Culturist." This was followed by the "Small Fruit Culturist," "Practical Forestry," "Propagation of Plants," and the "Nut Culturist." The last of them he was fond of calling his "monument," as he did not intend to write another book, and so fate decided that it should be. He died a few days after he had finished his manuscript, and never saw the completed book, of which he was perhaps more proud than of any other of his works, yet in the history of horticultural literature his "Small Fruit Culturist" will, no doubt, occupy the foremost rank. It was more instrumental in the development and building up of the great industry to which it is devoted than any book written before or after, and in any land. It was translated into German and published in Weimar in 1868. His books contain but a small part of his writings. His editorial and other contributions to the "American Agriculturist," to "The Rural New-Yorker," of which he was part owner for a time, the "New York Sun," of which he was agricultural editor for twenty-six years, "American Gardening" and other periodicals would fill hundreds of volumes. He was also editor of the "Record of Horticulture," 1866 and 1867. While Mr. Fuller was principally known as a horticulturist, there was hardly a branch of natural science to which he had not devoted more or less attention. His entomological collection, especially that of coleoptera, was one of the most complete in the country; his mineralogical and archeological collections contained many rare specimens, and his horticultural library was one of the best

1879. Andrew S. Fuller.

in the United States. In later years, although in good health, Mr. Fuller left his place but seldom, but in his earlier years he traveled considerably, and took an active and leading part in the meetings of the American Pomological Society, the American Institute Farmers' Club, the Fruit-Growers' Club, and many kindred societies, of which he was an active or honorary member.
F. M. Hexamer.

Fulton, J. Alexander, lawyer and horticulturist, was born at his father's farm in Armstrong County, Pennsylvania, November 11, 1822, and died in 1895. He removed from Pennsylvania to Dover, Delaware, in 1865. Although a lawyer by profession, he was much interested in fruit-culture and was known as a horticulturist far beyond the limits of his state. His book on "Peach Culture" was long a standard work. He was one of the early members of the Peninsula Horticultural Society and participated in its meetings until the end of his life.
G. B. Brackett.

Gale, Elbridge, pastor and horticulturist, was born on Christmas Day, 1824, in Bennington, Vermont. and died at Mongonia, Florida, in 1907. He attended Brown University and was later graduated from the Baptist Theological Seminary at New Hampton, New Hampshire. His first pastorate was at Johnson, Vermont; from thence he accepted a call to the Baptist church of Pavilion, Illinois, and on going to Kansas in 1864, became the pastor of the Baptist church at Manhattan. He remained in this pastorate until he accepted the chair of horticulture at the Kansas State Agricultural College. He was greatly interested in the free schools of Kansas and was County School Superintendent of Riley County for several terms. He was one of the founders of the Manhattan Horticultural Society. He removed to Lake Worth, Florida, November, 1884, on account of his failing health. His interest in horticulture grew apace in the Lake Worth section. He was first president and an active member of the Lake Worth Horticultural Society as long as it was in existence, and it was largely through his efforts that the United States Government procured from India some Mulgoba mangoes and from Italy some mangosteens, durians and figs for distribution to the planters connected with the Society. Of all the Mulgoba mangoes planted, Mr. Gale was the only one who succeeded in keeping the trees alive, and the Mulgoba mango still remains a living monument to his success as a Florida horticulturist. His skill and energy has given to the western world another fruit that adds much to tropical luxuriance and American finance.

His was a busy life. At the college at Manhattan he planted the college arboretum east of Horticultural Hall and the forest plats on the old college farm. In 1879 he was candidate for Congress from the First Kansas District, greenback platform.

To his activity, usefulness and teachings, thousands of pioneer Kansans and students of the College are indebted to this grand old man who sleeps beneath the live oaks and the palms of his new home State in the Southland.
G. B. Brackett.

Gano, William Groves, pioneer horticulturist of the Missouri Valley and introducer of new varieties of fruits, was born in Winchester, Virginia, in 1839 and died at Parkville, Missouri, in 1910. In 1867 he moved to Parkville, Missouri, where he planted one of the notable early orchards of that section and spent most of the active working part of his horticultural career. He was associated with J. C. Evans and others in establishing and planting the Olden Fruit Farm, the pioneer large commercial orchard of the Ozark region. Throughout his residence in Missouri, he was a member of the Missouri State Horticultural Society and served frequently as an officer of this body. He was also a charter member of the Missouri Valley Horticultural Society and held membership in other state and national organizations. He was actively identified with collecting state fruit exhibits at all of the leading national and interstate expositions which have been held during the past fifty years. He was awake to the desirability of introducing and testing large numbers of varieties of fruits on his farm at Parkville. His orchard served largely as a model for the guidance of other orchardists in his own section and his advice and judgment as to what varieties to plant and how to adapt orchard management to this pioneer section of the Missouri Valley was sought throughout several states. In addition to giving his time and his resources freely to this type of work, he was zealously interested in the production of new seedling varieties of fruits. Several of these have gained local prominence because of their adaptation to local conditions. His most celebrated contribution to our list of varieties was the Gano apple, named in honor of the originator by Charles Downing. The Gano apple is similar to that most cosmopolitan Ben Davis, equal to it in every respect, but due to its superiority over Ben Davis in color and beauty of appearance, it is now displacing the latter in commercial orchards of the West. The annual reports of the Missouri State Horticultural Society contain many of his papers dealing with the problems and practices of fruit-growing which he helped to shape in the region in which he did his work.
J. C. Whitten.

Garey, Thomas Andrew, nurseryman, was born in Cincinnati, Ohio, July 7, 1830, and died at Los Angeles, California, August 21, 1909. He was of German stock and spent his boyhood partly in Hagerstown, Maryland, and partly in Iowa. In the spring of 1850, Mr. Garey moved to New Mexico, traveling by ox-team over the Santa Fe trail. In 1850, after having married in New Mexico, the Gareys crossed the mountains and settled at El Monte in Los Angeles County, California, where he engaged in farming. In 1865 Mr. Garey purchased 72 acres of land on what is now South San Pedro Street, Los Angeles, and entered the nursery business. He soon built up a large and thriving business and was very active in introducing many kinds of tropical and semi-tropical fruits from various parts of the world. It was Mr. Garey who first demonstrated to the citrous growers that budded trees of improved varieties were better than the seedlings which were commonly grown. Hearing of the Bahia Navel orange, Mr. Garey attempted to introduce it from Australia, but was unfortunate in securing an undesirable type (Australian Navel) which was subsequently displaced by the true Bahia or Washington Navel. Recognizing the value of a seedling lemon grown by C. R. Workman, Mr. Garey bought the original tree and introduced the variety in 1877 under the name Eureka. This variety is now the leading commercial lemon in California. Mr. Garey did a large business in importing all kinds of plants and seeds and had wonderful success with many of the novelties he brought in. He served for a time as president of the Los Angeles Pomological Society and was one of the founders of the city of Pomona. In 1882 he published "Orange Culture in California," which for years was considered a standard reference book.
J. Eliot Coit.

Gibb, Charles, Canadian horticulturist, and author of important works on Russian fruits and other hardy trees, was born at Montreal June 29, 1842 (Woolverton says 1846) and died at Cairo, Egypt, March 8, 1890, while returning from a collecting trip in China and Japan. In 1872 he brought to Montreal the first canned fruit exhibited in Canada. His farm at Abbotsford, Province of Quebec, contained the best collection of hardy fruits, trees and ornamental shrubs in Canada. His trip to Russia in 1882 with Professor Budd, the subsequent importations, his second trip to Russia, and his various publications on hardy trees make part of a chapter of great interest and significance in the history of American horticulture. His travels were extensive. His chief works are "Ornamental and Timber Trees not Natives of the Province of Quebec" (a comprehensive list of species of possible value for Canada), "Report on Russian Fruits," "Hasty Notes on the Trees and Shrubs of Northern Europe," "Russian Apples Imported by the Department of Agriculture, Washington, in 1870" (an elaborate comparison of Russian opinions and American experience), "Nomenclature of the Russian Apples," "Of Translating and Rendering into Euphonious English Unpronounceable Russian Names, also Throwing Out Synonyms," and "Fruits for the Cold North." For a fuller account, with portrait, see "Annals of Horticulture," 1890, 287–290. Wilhelm Miller.

Gideon, Peter M., pioneer pomologist of the northern Mississippi states, 1818–1899, resided since 1853 on Lake Minnetonka, Minnesota, and devoted his efforts to the production of apples of sufficient hardiness to withstand the climate. He was born in Ohio. He afterward lived in Illinois. From boyhood he seems to have been possessed of the idea to raise seedling fruits. He was one of those rare individuals who sets a distinct ideal and strives for it throughout a lifetime in spite of every adversity. These are persons of strong and uncompromising will. They often antagonize their fellows; but their works are usually beneficent. Gideon conceived that the amalgamation of the Siberian crab and the common apple would give the perfect apple for the Northwest. His seedlings were numerous. Several of them have been named and disseminated, and are of value. But his greatest achievement, the Wealthy apple, was of pure *Pyrus Malus* stock. This variety is now one of the standard apples of his geograpical region, and it is also in favor elsewhere. It is a boon to the Northwest. Even when in poverty, it is said that Mr. Gideon spent his last dollar to buy the seeds from which this apple came. He was instrumental in distributing 10,000 apple seedlings in Minnesota, and some of these are now attracting attention. His work was wholly empirical, yet he did so much and continued his work for so long a time that the results have contributed to the knowledge of plant-breeding. Probably no other American has labored so long and devotedly for the attainment of a specific ideal in the apple. Portrait and eulogies will be found in "The Minnesota Horticulturist," January, 1900. L. H. B.

Goff, Emmett Stull, horticulturist, was born on a farm near Elmira, New York, in 1852. In 1882, he was appointed horticulturist at the Agricultural Experiment Station at Geneva. In 1889, he was called to the University of Wisconsin as professor of horticulture and horticulturist of the experiment station. He did valuable work in producing new and hardy varieties of plums for the colder portions of the Northwest. He was a pioneer in spraying and invented the kerosene attachment for spray pumps. Professor Goff performed the first successful experiments with fungicides for the control of the apple-scab fungus. He was the author of "Principles of Plant Culture," and "Lessons in Pomology" and wrote the first classifications of vegetables published in America. He also published many bulletins and papers in horticultural publications. He was a good systematic botanist as well as a horticulturist. He died at Madison, Wisconsin, on June 6, 1902. For portrait and fuller account, see "Cyclopedia of American Agriculture," Vol. IV, p. 576.

Goodrich, Chauncey, bookseller and horticulturist, was born September 10, 1798, and died September 11, 1858, at Hinsdale, Massachusetts. At nineteen years of age he entered a publishing house, but a few years later took up bookselling and publishing on his own account, finally settling at Burlington, Vermont. He was very much interested in gardening, testing fruits for hardiness in the Champlain Valley and maintaining a nursery on his farm. He did much to improve and extend the culture of fruits in northern New York and Vermont. He was a contributor to horticultural magazines and author of "The Northern Fruit Culturist, or Farmer's Guide to the Orchard and Fruit Garden." For a fuller account, see "Cyclopedia of American Agriculture," Vol. IV, p. 579.

Green, Samuel B. (Fig. 1880), horticulturist and educator, was born in Chelsea, Massachusetts, September 15, 1859, and died in Itasca Park, Minnesota, July 11, 1910. His father was one of the early mayors of Chelsea and held many offices of trust. As a boy, Professor Green spent his summers on a New Hampshire farm and early developed a liking for farm life, culminating in his taking the agricultural course at Amherst, in spite of strong opposition from his family and friends, who wanted him to take up other work. He worked a large part of his way through college, graduating in 1879. Immediately after he graduated, he became superintendent of the Vine Hill Dairy Farm, of West Hartford, Connecticut. After a year's experience, he decided there was not a great future for agriculture in the East and took up gardening and nursery work. He worked for a market-gardener near Boston one season, then took a six-months' post-graduate course at Amherst. The next season he worked for James J. H. Gregory, and in the winter, for William C. Strong, a rose-grower and nurseryman of Brighton, Massachusetts. About 1884 he took charge of the Horticultural Department of Houghton Farm Experiment Station, at Cornwall, New York. He made many interesting experiments here and also had the opportunity to get some landscape gardening training under Samuel Parsons, Jr., who was employed to develop the Houghton Farms of over 1,000 acres. Thinking that he was not getting enough experience here, he returned to Mr. Strong's nursery especially to learn summer propagation of plants, later becoming foreman of Newton Cemetery nurseries. From here he returned to Massachusetts Agricultural College as foreman of the horticultural department. He remained here until 1888 when he accepted the position of professor of horticulture and applied botany in the University of Minnesota and horticulturist of the experiment station. Later his title was changed to professor of horticulture and forestry, and in 1910 he was made dean of the College of Forestry. He was a member of the Executive Board of the Horticultural Society, Forestry Board, American Pomological Society, Society of American Foresters and American Forestry Association. At the time of his death, he was president of the State Horticultural Society and of the State Board of Arbitration.

1880. Samuel B. Green.

Professor Green wrote many books and bulletins and contributed to the agricultural literature generally.

His best known publications are: "Amateur Fruit Growing," 1894; "Vegetable Gardening," 1896; "Forestry in Minnesota," 1898; "Principles of American Forestry," 1903; "Farm Hedges and Windbreaks," 1906; "Popular Fruit Growing," 1909.

He was one of the pioneers who helped to put agriculture in its proper place in the state of Minnesota. He was instrumental in establishing the College of Forestry and started the summer work in Itasca Park, thus giving the forestry students six months of practical work under good supervision. Le Roy Cady.

Gregory, James J. H., farmer, seedsman, and author, was born at Marblehead, Massachusetts, November 7, 1827, and died February 20, 1910. He was educated in the public schools at Marblehead, two years at Middlebury College, and graduated from Amherst College in 1850. He taught in Marblehead, Hingham and Lunenberg. The starting of the seed business was almost an accident. He was reading the "New England Farmer" and saw the request for a good winter squash, and as his father had recently raised some splendid squashes from seed that "Old Marm Hubbard" had given him, he sent the inquirer some of this seed. The man was so well pleased that he wrote articles for several papers extolling these squashes, and soon the Gregory Seed Business was thriving, sending Hubbard squash seed to all parts of the United States. Naturally the business started in the home, the attic being used for the purpose; in a very short time it was necessary to move to larger quarters. He branched out with other seed, both vegetable and flower, and at the time of his death was carrying on one of the largest seed establishments in the country. During his career he introduced many new varieties of vegetables, several of which are the standards in the market today. His seed-farms comprised over 400 acres where he grew pedigreed stock; he always felt that by growing his own seeds he was less liable to mistakes and could, himself, select the most perfect types. His reputation for choice varieties was so renowned that the firm became the headquarters for stock seeds for other well-known concerns.

He wrote and distributed many thousands of copies of treatises on various agricultural subjects, such as: "Onion Raising," 1865; "Squashes: How to Grow Them," 1867; "Cabbages and Cauliflower," 1870; "Carrots, Mangold Wurtzels and Sugar Beets," 1877; "Fertilizers," 1885. In his early life he lectured extensively on agricultural and horticultural subjects.

Mr. Gregory was a philanthropist of renown. He gave large sums of money for the establishment of southern schools and colleges, the Gregory Institute of Wilmington, North Carolina, being founded by him. He served his native town in many responsible capacities and filled many public offices. Edgar Gregory.

Hall, Dr. George R., plant collector, was born in Bristol, Rhode Island, in 1820, and died in Milton, Massachusetts, December 24, 1899. He was a graduate of Trinity College, Hartford, Connecticut, in the class of 1842. He studied medicine at the Harvard Medical School, class of 1846, and on receiving his degree went to China, where he practised medicine in the foreign settlement in Shanghai. He abandoned the practice of medicine in 1854 and went to Japan, where he traveled extensively and collected the plants which bear his name, among which may be mentioned *Lonicera japonica* var. *Halliana*, *Pyrus Halliana*, *Magnolia stellata* (*M. Halliana*), *Zelkova Keaki*, *Retinospora*, *Thujopsis*, and *Lilium auratum* which flowered in this country one month earlier than in England. In 1864 he planted at Bristol many Japanese evergreens at that time very rare in this country. In 1876 he made a second visit to Japan.

Harris, John S., horticulturist and pomologist, was born in Seville, Ohio, August 17, 1826, and died at La Crescent, Minnesota, March 24, 1901. His ancestors were hardy pioneers of Massachusetts and Connecticut, and his own parents were pioneers in Ohio. Mr. Harris early became a skilful propagator of plants under the direction of his father and at the age of eleven had a small nursery and garden of his own. After his father's death in 1844, he was apprenticed to a cabinet-maker to learn the business. In 1847 he enlisted for the Mexican war and served under General Scott in the campaign resulting in the capture of Mexico City. After his return from the war, he stayed in Ohio a year or so and then went west to Wisconsin, traveling over Wisconsin, Iowa and Illinois. In 1851 he settled at La Crosse and engaged in market-gardening. The soil proving too poor and sandy, in 1856 he removed to La Crescent and started in the fruit, garden and florist business.

He planted his first orchard in 1857 and continued planting trees, plants and shrubs until the last few years of his life. It was his pride that he had tried nearly every variety of apple that offered any likelihood of being valuable to Minnesota planters. The winters of 1872 and 1884 destroyed nearly all of his trees but he continued planting. He began to attend fairs and exhibit fruits of his own growing in 1864. In 1866 he helped organize the State Horticultural Society and his is the first name on the roll of the Society. In 1868 he was elected vice-president and in 1869, president. He held the office of president until 1871, and again from 1881 to 1884. He was a member of the executive committee from 1884 until his death. He was elected to the Board of Managers of the State Agricultural Society in 1875 and held the office for twelve years. Mr. Harris exhibited at the state fair every year and his exhibits were always interesting and valuable as showing the pomology of the state. He was one of the first men to be made an honorary life member of the Horticultural Society. He enjoyed writing for the agricultural papers and conducted a column in the "Farm, Stock and Home" for many years. Mr. Harris probably had a closer knowledge of pomology in the Northwest than any other man in the United States and did his full share in the development of horticulture throughout Minnesota.

Le Roy Cady.

Heikes, William Fletcher, nurseryman, was born at Dayton, Ohio, on April 2, 1837. He succeeded his father in the nursery business near Dayton, in 1839. In 1872 he established near Huntsville, Alabama, what eventually became the largest nursery of its kind in the United States. He was instrumental in introducing systematic grading and was the first nurseryman to use a caliper to determine tree grades. He was also the first nurseryman to cellar nursery stock and keep it in cold storage during the shipping-season. Mr. Heikes originated the double root-grafting method of propagation of nursery stock. He was state vice-president for Alabama of the American Pomological Society for many years. He was president of the Alabama Horticultural Society from its origin in 1903 to the time of his death in Cleveland, Ohio, on Friday, August 25, 1911.

P. F. Williams.

Henderson, Peter (Fig. 1881), leading market-gardener, florist, seedsman and author, was born at Pathhead, near Edinburgh, Scotland, in 1822, and died in Jersey City, January, 17, 1890. He was trained in Old World methods of gardening, came to America in 1843, worked under Thorburn and Robert Buist, and then in 1847 began business in Jersey City as a market-gardener, with a capital of $500, saved by three years' hard work. He continued to live there until his death. The publication of "Gardening for Profit" in 1865 marks an era in American horticulture. It was the first American book devoted entirely to market-gardening, and it helped to induce many persons to enter the business. By the time of his death about 150,000 copies of the book are said to have been distributed. It was written in an aggregate of 100 hours, when the author was working 16 hours a day, largely at manual labor. At the noon intervals and late at night he wrote this work lying on his back, with a pillow under his head. The secret of its success and of the author's, was the invention of new methods adapted to operations on a large scale. The second edition in 1874, and the third in 1887, are both thorough revisions.

1881. Peter Henderson.

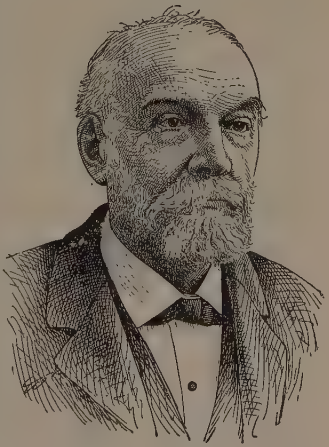
"Henderson's Practical Floriculture," 1868, was an epoch-making book in commercial floriculture. Up to this time most works on flower-gardening had been written for the amateur. This point of view is necessarily the commoner one, and Henderson's contribution to it was "Gardening for Pleasure," 1875. In the compilation of "The Handbook of Plants," in 1881, he was largely aided by C. L. Allen, and in the second edition, 1890, by W. J. Davidson. "Garden and Farm Topics" was issued in 1884, and in the same year appeared "How the Farm Pays," a stenographic report of conversations between Wm. Crozier and Peter Henderson. It is said that nearly a quarter of a million copies of his various works have been sold. His seed business was founded at New York in 1865.

Few men, if any, have done so much to simplify and improve methods of handling plants for commercial purposes. His greenhouses were an object lesson to many visitors, his methods were widely copied, and his business successes were the goal of ambitious market-gardeners and florists, among whom he was for many years the most commanding figure. He was a frequent contributor to the horticultural and agricultural magazines, and during his forty-two years of business life is supposed to have written or dictated at least 175,000 letters. Two-thirds of these letters were written with his own hands, and he always replied promptly to inquiries about methods of cultivation. An account of his life is published in a memoir of forty-eight pages by his son, Alfred Henderson. Wilhelm Miller.

Hepburn, David, was joint author with John Gardiner of a very early American book on horticulture. This was published at Washington, D. C., in 1804. The name of Gardiner appears first on the title page, but it may be inferred that the practical experience in the book is almost wholly Hepburn's. He had had forty years of experience in gardening, half of the time in England and half in America. He was employed by General J. Mason for six years on Mason's Island, Georgetown. He had also been employed by Governor Mercer. The book was well made for the time. It is a 16mo, and contains 204 pages of practical directions. The calendar style is used. The first part (100 pages) is devoted to the kitchen garden. The second part consists chiefly of fruits, flowers, and shrubs (82 pages). This is followed by a few pages on hops, hot-houses and greenhouses. The second edition (Georgetown, 1818) contains 348 pages. It includes "A Treatise on Gardening, by a citizen of Virginia." This occupies 80 pages. The copy owned by the Massachusetts Horticultural Society possesses this manuscript note: "This treatise is by John Randolph, of Williamsburg, father of Edmund Randolph, Secretary of State during the administration of General Washington." Robert Manning said that this note may have been made by General Dearborn. A third edition was published at Washington in 1826, and contained 308 pages. For a further account of the book by Gardiner and Hepburn, see page 1521. Wilhelm Miller.

Hexamer, Frederick M. (Fig. 1882), physician, nurseryman and editor, was born at Heidelberg, Germany, on June 21, 1833. He died at Stamford, Connecticut, May 29, 1909. When only sixteen years of age, he joined Siegel's army which was disbanded in 1848, and he, the youngest in the ranks, being exiled, went to Switzerland, where he became acquainted with the elder Froebel with whom he studied medicine and botany in the Zurich botanical gardens. Having secured his M.D. degree, he explored the Swiss Alps and the Tyrol and made a very large collection of Alpine plants. The remains of this collection are now in the herbarium of the botanical gardens at Bronx Park, New York City. About the middle of the last century, he came to New York and began the practice of medicine, which, however, he soon dropped to enter the nursery business at Chappaqua, New York, in partnership with his father-in-law, a leading physician of New York City, under the name of Reisig & Hexamer. The firm's principal business was the growing of new varieties of plants to be distributed as premiums with the "New York Tribune," to which paper Dr. Hexamer became a contributor through his friendship with Horace Greeley. His writings were upon horticultural and agricultural topics. Thanks to his friendship with B. K. Bliss, he became editor of the "American Garden" in 1880. In 1885 he succeeded Dr. George Thurber as editor of "American Agriculturist," to which paper he had contributed frequently during many years. He continued as editor of the "Agriculturist" until the early years of this century, when he was made editor emeritus. His activity during his connection with the "Agriculturist" had also to do with the editing of a large number of books on rural affairs published by the Orange Judd Company. His only book, "Asparagus," the sole work on this subject published in America, was printed in 1901.

In addition to the influence which he exercised on American farm affairs as editor, Dr. Hexamer was a leading spirit in horticultural and agricultural associations. He was for years on the New Fruits Committee of the American Pomological Society and was president of the Farmers' Club of the American Institute of New York City, his immediate predecessor being Horace Greeley. In this institution, he mapped the policy of the club which practically took its life and usefulness from him. However, owing to his excessive modesty, his hand was not often seen and only too frequently others seized the credit which was really due to him.



1882. F. M. Hexamer.

Some of his achievements in the commercial line had to do with the growing of strawberries and potatoes. He was the first man to grow the former on a business basis for the New York market. He also grew the epoch-making Early Rose potato for the introducers and was awarded a medal at the Centennial Exposition at Philadelphia in 1876 for a collection of 550 named varieties of potatoes. M. G. KAINS.

Hiester, Gabriel, horticulturist, was born at "Estherton," near Harrisburg, Pennsylvania, April 28, 1850, and died in his lifelong home, January 18, 1912. His father, Augustus Otto Hiester, was a prominent citizen and an influential trustee of the Pennsylvania State College. Gabriel Hiester graduated from this institution in 1868 and served as a trustee from 1878 until his death. No member of the board did more for the promotion of agriculture, and especially horticulture, in the college and in the agricultural experiment station. He was elected President of the State Horticultural Association in 1905 and was serving his eighth term on the evening before his death. Mr. Hiester was widely known as an unusually successful horticulturist. He produced fruits and vegetables on a large scale for the markets of central Pennsylvania and frequently attended Farmers' Institutes and horticultural meetings in this and other states where he gave his hearers the benefit of his many years of experience as a grower of choice products. Gabriel Hiester was a man of sterling qualities, being broad-minded, unselfish, and thoroughly devoted to all interests which concern the welfare of mankind. R. L. WATTS.

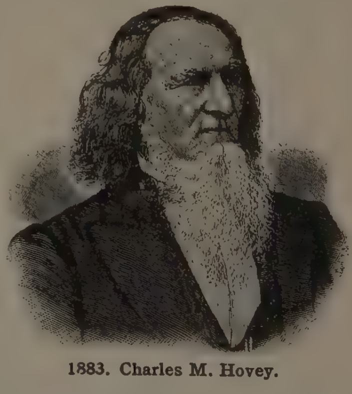
Hogg, Thomas, Senior and **Junior**, plantsmen. The second Thomas Hogg, born in London, February 6, 1820, died in New York, December 30, 1892, was known for his introductions of Japanese plants. His father removed to this country in 1820, when the child was nine months old, and early in 1822 took up a piece of land outside the city of New York, at what is now Broadway and Twenty-third Street, and here established himself as nurseryman and florist. In 1840, the nurseries were removed to Seventy-ninth Street and East River, where young Thomas and his brother James assisted in the business. The father died in 1855, and the sons took charge of the business. Thomas Hogg was appointed by President Lincoln, in 1862, United States Marshal, and in this capacity he resided eight years in Japan. He returned to Japan in 1873, and remained two years in the Japanese customs service. "His close relations with the authorities gave him opportunities for exploring the islands which other foreigners did not possess, and he collected many plants and seeds of horticultural value and sent them home. The garden of his brother at the foot of Eighty-fourth Street, where most of these treasures were cultivated for the first time in America, was, for many years, the most interesting spot in the United States to the lovers of Japanese plants. Many of the very best trees, shrubs and herbaceous plants which have come to us from Japanese gardens were thus brought to America before they were sent to Europe, and not a few of them are now among the most familiar inhabitants of our gardens." Hogg left Japan in 1875, and subsequently traveled in China, Ceylon, South and Central America, as well as in Europe and California. In later life he devoted himself to his favorite studies. He never married.—Extract from "Garden and Forest," Vol. VI, p. 24.

Hoopes, Josiah, nurseryman, was born in West Chester, Pennsylvania, November 9, 1832, and died January 16, 1904. He was reared principally in Philadelphia and received a superior English and classical education in the high schools of that city. His chief delight was in botany, and from early childhood he pursued that line of study with interest. It was in pursuance of his inclinations along this line that he built in 1853 a small greenhouse on his father's property and proceeded, at great labor and considerable expense, to fill it with specimens of the flora of this continent and of the world. To this collection he added as opportunity permitted and naturally began propagating them and found his products in demand. From that small beginning, the great and prosperous nursery business of today was developed. Josiah Hoopes wrote much on horticulture, botany and kindred subjects, for many years being a regular contributor to the horticultural department of the "New York Tribune" and other publications. He was the author of the "Book on Evergreens."

Hoskins, Thomas H., physician, horticulturist and writer, was born at Gardiner, Maine, in 1828 and died at Newport, Vermont, in 1895. He was well known in horticulture as the introducer of Russian fruits. He was also a contributor to all the the leading horticultural papers. For a fuller account, see "Cyclopedia of American Agriculture," Vol. IV, p. 585.

Hovey, Charles Mason (Fig. 1883), horticultural journalist and nurseryman, was born in Cambridge, Massachusetts, October 26, 1810, and died there September 1 or 2, 1887. He is best known as editor of the "Magazine of Horticulture," which had an uninterrupted existence from 1835 to 1868. It was founded as the "American Gardener's Magazine," by C. M. Hovey and his brother, Phineas Brown Hovey. In its third volume (1837) it changed its name, and continuously thereafter was known as the "Magazine of Horticulture," and was edited by Charles M. Hovey alone. It enjoyed the longest period of prosperity of any American horticultural journal. It is a record of the budding stage of New World horticulture. It was modeled after Loudon's "Gardener's Magazine," although its spirit was essentially American. Essays, records of current events, reviews of books, descriptions of varieties, were prominent features. It had very few illustrations. Mr. Hovey was author of the "Fruits of America," issued in parts from 1852 to 1856, completing two volumes and making more than a beginning on a third. Its purpose was to give "richly colored figures and full descriptions of all the choicest varieties cultivated in the United States." The volumes contain more than 100 colored plates. Handsomely printed and bound, these volumes are a fine type of the amateur's art-book of varieties.

Mr. Hovey was also nurseryman and seed merchant. Until 1840, his grounds at Cambridge are said to have comprised only an acre, but at that time his premises were greatly enlarged. His epoch was a time of knowledge of varieties. Straightway he began assiduously to collect varieties, until he exhibited pears, apples and camellias by the hundreds, and plums, grapes, chrysanthemums and many other things by the score. These things were shown before the Massachusetts Horticultural Society which was the center of horticultural influence of the country. He raised many seedlings. *Thuya Hoveyi* is still prized as a garden conifer. His greatest contribution to horticultural varieties was the Hovey strawberry, which first fruited in 1836, and which is generally regarded as the starting-point of American commercial strawberry-growing. For many years this berry was the standard of market excellence (Fig. 1861). He continued to grow it and cherish it until the end. Mr. Hovey was long an active member, and for a time president, of the Massachusetts Horticultural Society. He was one of the active projectors



1883. Charles M. Hovey.

of the building which gave the Society a new and more commodious home.

A portrait of Mr. Hovey will be found in the first volume of the "Fruits of America." Another occurs in "Gardeners' Monthly" for 1886 (frontispiece) and "American Garden," November, 1887; and a reduction of this appears in Fig. 1883. L. H. B.

Hunnewell, Horatio Hollis (Fig. 1884), philanthropist and horticulturist, was born in Watertown, Massachusetts, July 27, 1810, and died in 1902 at Wellesley, Massachusetts. He was the eighth in line of descent from Roger Hunnewell, who came to this country from England in 1640. Hollis Hunnewell was educated at Harvard University and in Paris. At twenty-five years of age, he became a partner in the banking-house of Wells & Co., a Parisian bank for the accommodation of American tourists. He was later identified with the banking and railroad interests of the United States and many philanthropic movements, but the singular fact remains that he did not manifest a taste for arboriculture and horticulture, his favorite pastime, until he was over forty years of age. He was first to introduce the use of *Catalpa speciosa* for railroad ties, and hundreds of acres of catalpas were planted on the treeless plains along the lines of western railroads. Through his efforts, the first open-air exhibition of rhododendrons and azaleas was given in Boston in 1873. No previous attempt had been made in this country to bring together a large collection of these plants for landscape effect. The increased excellence and extent of arrangement of grouping of plants hitherto unused made him a landscape artist of first degree, and he gave a new impetus to American botany and horticulture. He was president of the Massachusetts Horticultural Society for 1875 and through his numberless benefactions helped to make horticulture a household word, not only in his beloved state, but throughout the country. G. B. Brackett.

1884. H. H. Hunnewell.

Husmann, George, grape-grower and author, was born at Meyenburg, near Bremen, Germany, November 4, 1827, and died at Napa, California, November 5, 1902. He came to the United States at an early age and was practically self-educated. His horticultural career began at Herman, Missouri, where he established the largest and oldest American vineyard that turned grapes into wine, with the exception of the Longworth vineyard in Ohio. He served with distinction in the Civil War, was a presidential elector in 1866, and was a member of the convention for revising the constitution of the state of Missouri. He established extensive nurseries and a model fruit farm that was the pride of the state, and the fruits and wines received first awards at all the fairs and expositions held at that time. In 1866, he published his first book, "Grapes and Wine." About 1869 he began the publication of the "Grape Culturist." In 1880 his second book, "Grape-growing and Wine-making," was published, and in 1888 "Grape-culture and Wine-making" was issued, and it became so popular that it was revised and published through four editions. He was president of the Bluffton Wine Company, Bluffton, Missouri, a member of the Board of Curators of the Missouri State University, a charter member of the Missouri State Horticultural Society and the Missouri State Board of Agriculture; professor of pomology and forestry, Missouri State University; a member of the Viticultural Congress that convened at Washington, D. C., and State Statistical Agent for the state of California. He was one of the first men to ship American phylloxera-resistant grape-vines to France to re-establish her vineyards. In coöperation with Parker Earle, he originated and helped to organize the Mississippi Valley Horticultural Society.
G. B. Brackett.

Jack, Mrs. Annie L. (Fig. 1885), was born in Northamptonshire, England, January 1, 1839, and died in February, 1912. Her maiden name was Annie L. Hayr. In 1852 she came to America and pursued her studies at a ladies' seminary in Troy, New York. She taught school at Chateauquay Basin, Quebec, about a dozen miles from Montreal, and later was married to Robert Jack of that place. Acting under her influence, their farm, known as "Hillside," was largely planted to small-fruits and vegetables, to which was in time added a greenhouse for floriculture. Thus were demonstrated the capabilities of that section for market-gardening, and others were led to follow the example so successful at the "Hillside" farm. But it was as a writer on horticultural subjects that Mrs. Jack is most widely known. Her "Garden Talks" and other contributions to the press have much value, being the product of her own practical experience. Her handbook entitled "The Canadian Garden" is of especial value to Canadian gardeners.
Linus Woolverton.

1885. Mrs. Annie L. Jack.

Jaeger, Herman, pioneer grape-grower of the Ozarks and grape-breeder, was born in Brugg, Switzerland, in 1844, and died in 1896. He went to Missouri in 1867 and settled at Neosho, where, until 1896, he lived and engaged in viticulture. In Europe he was trained as a viticulturist. At Neosho, in 1869, he planted a large vineyard. It was composed largely of Concord and other eastern types of grapes. In 1873 "blight" (probably downy mildew) destroyed his crop of grapes. In 1874 he began spraying to control this blight or mildew, using sulfur, iron sulfate and copper sulfate He was undoubtedly the first to begin spraying for fungous diseases in this western section. This pioneer work in which he contemplated the use of fungicides, which became general with the introduction of bordeaux mixture a few years later, is an indication of his resourcefulness and his vision. The failure of eastern grapes to resist mildew turned his attention also to the native wild grapes of the Ozarks, which he observed to be resistant of disease. As a result, for a third of a century, he searched the Ozarks for promising wild forms. From these he originated many promising native seedlings and also crossed many of the latter with Concord and other eastern sorts. He advocated the use of the native post oak and summer grapes *Vitis Lincecumii* and *V. æstivalis* as the foundation stock upon which to build the future viticulture of the Ozarks. He originated upward of one hundred varieties worthy of trial in the neighborhood and many of his pioneer varieties have become the foundation stock upon which other grape-breeders base their work. He also observed that the native Ozark grapes were free from the phylloxera which threatened the grapes of his native Europe. He was one of the first to make use of this observation by propagating millions of cuttings and sending them to Europe where they were used as resistant stocks upon which to graft European varieties.

He wrote but little and shrank from giving the results of his work before horticultural gatherings. He taught by personal contact and by results attained. His acquaintances, during his life regarded him as the leading grape-breeder and viticulturist of the Ozarks.

J. C. Whitten.

Kennicott, John A., doctor and pioneer horticulturist, was born in 1800 and died in 1863. When the greater part of Illinois was a wilderness of grass prairie and when Chicago was a straggling village, Dr. Kennicott was planting shade and ornamental trees at his home. He was a leading spirit in the organization of the Cook County Agricultural and Horticultural Society in 1856, and held the first successful fair in 1857 on forty acres that later held solid blocks of sky-scrapers. This horticultural society was short-lived, but Dr. Kennicott did much to stir up the farmer and the fruit-grower to the possibilities wrappd up in horticulture in Illinois. He was a ready writer and a good talker; he was first president of the Northwestern Fruit-Growers' Association and president of the Illinois State Horticultural Society in 1861. Dr. Kennicott was well educated, painstaking and self-denying. He did much for Illinois horticulture and the present generation owes him a lasting debt of gratitude for his noble, far-reaching pioneer work in horticulture.

G. B. Brackett.

Kenrick, William, nurseryman and author, was born in 1795, and was the oldest son of John Kenrick, one of the pioneer American nurserymen. His father commenced his nursery in the year 1790 on Nonantum Hill, near the line of the towns of Newton and Brighton, Massachusetts, and on the very ground where the apostle Eliot began his labors for the Indians, under Waban, their chief. The raising of peach seedlings was the commencement of Mr. Kenrick's work. He soon acquired the art of budding, and thus offered named varieties for sale. In the year 1823 his son William became a partner in the nursery, and we find the first advertisement of the stock in the October number of the "New England Farmer" of that year. It named thirty varieties of finest budded peaches 5 to 8 feet high at 33⅓ cents each; ten varieties of European grapes; four American: Isabella, Catawba, Bland and Scuppernong; currants, horse-chestnut, catalpa, mountain-ash, lilacs, roses and a few other ornamental trees. It was stated that the trees would be packed with clay and mats. The son, William, appears to have assumed early control, having planted in 1823 two acres in currants alone. In 1824 they made 1,700 gallons of currant wine, increasing the amount to 3,000 gallons in 1825 and to 3,600 in 1826. Mr. Kenrick was an enthusiast in whatever he did, his extensive cultivation and introduction of the Lombardy poplar being an illustration of his sanguine temperament. A still more marked instance was his culture of the *Morus multicaulis* about the year 1835, and his advocacy of silk culture. For a time he found this to be a more profitable venture to himself than to his patrons. But it should be said that, however sanguine and confident were his opinions, they were honestly held and with no intent to mislead. In the year 1835, Mr. Kenrick published "The American Silk-Growers' Guide," a small treatise on mulberry-culture. In 1833 appeared the "New American Orchardist." This is a larger work, and is a full description of the fruits of that date. The author acknowledges his large indebtedness to other cultivators, especially to Mr. Robert Manning, of Salem, who published his "Book of Fruits" in 1838. Mr. Kenrick died in February, 1872.

Wm. C. Strong.

Kerr, Jonathan Williams, fruit-grower and nurseryman, was born in York County, Pennsylvania, in 1842. In 1867, after the Civil War, in which he was a Union soldier, he went to Maryland, where he made his home. Prior to his soldier's life, he had taught school. After more than fifty years devoted to horticulture, he died on July 31, 1913, of heart disease. Not only did he devote time to the growing of nursery stock for sale and of fruit for market, but spent much of his energies in the testing of new fruits and nuts to determine their value, especially in the Chesapeake Peninsula. He was one of the most diligent of watchers and students of nature as affected by art, his constant effort being to improve by cross-fertilization and selection those fruits, nuts and other plants that gave promise of being satisfactory either from the commercial or the amateur's standpoint.

This work involved an enormous amount of labor in collecting and trying out thousands of plum, apple, peach, and other fruit varieties, the plum receiving the lion's share of his study and effort. In this work, Mr. Kerr was perhaps the leading specialist in the development and improvement of our native plums. Whenever and wherever a variety of reputed superiority came to his attention he spared no pains or money to procure it and no efforts to give it a fair test. He passed careful judgment on more than 400 named varieties, the labor involved being as nothing compared to the pleasing and fascinating task he imposed upon himself. His farm at Denton, Maryland, was "a veritable little plum heaven" visited by other enthusiasts from all over the world.

Mr. Kerr also tested more than 400 varieties of apples collected with the object of ascertaining their adaptability to the peculiar conditions of the Chesapeake peninsula. The larger part of these were varieties of reputation established elsewhere, though many were comparatively new. He was also especially interested in nuts which could be grown in the peninsula—Persian and Japanese walnuts, chestnuts, chinquapins, filberts, pecans, and so on. At the time of his death, scores of experiments were still in process of completion.

At fruit-growers' meetings, more especially those of the Maryland State and the Peninsula Horticultural Societies, Mr. Kerr was one of the leading spirits. His intimacy with all branches of horticulture and his fluent speech combined with his dry humor and aptness of tongue made his remarks particularly pleasing, interesting and instructive. His writings are characterized by extreme conservatism and care.

M. G. Kains.

Kirtland, Jared P., doctor, pomologist and naturalist, was born in Wallingford, Connecticut, November 10, 1793 and died near Cleveland, Ohio, December 11, 1877. His love for nature and all living things manifested itself in his early boyhood, and he was familiar with the flowers, the trees and the birds around his home. His grandfather bequeathed him his medical library and the funds for a medical education. He was the first student to matriculate at Yale College for a course in the Medical Department. No branch of scientific study came amiss to him. Prominent in medicine, he was in every chosen department of science a teacher and a leader. In the geologic survey of Ohio he brought to bear his extensive and familiar knowledge of the flora and fauna, the pomology, ornithology and entomology of the state. Every department of life received his particular care. He filled the chair of Theory and Practice in the Ohio Medical College for some years with great ability. As far back as 1810 he was studying the seedling pear trees in the nurseries in northern Ohio, and was trying to solve the perplexing problem of pear blight. He grew many varieties of pears and by a series of hybridizing produced many new varieties of pears and more than thirty new varieties of cherries; among the latter are the noted Governor Wood, Kirtland's Mary, Black Hawk, Pontiac, Powhatan, Tecumseh, Osceola and Red Jacket. The varieties were introduced by Ellwanger & Barry, of Rochester, New York. The Governor Wood and the Rockport are the two varieties of all the long list that are today most widely cultivated. In 1874 the Ohio Horticultural Society, in its session at Akron, sent a vote of thanks to Dr. Kirtland at Cleveland for his success and skill as a cultivator of new fruits. He was one of the most distinguished men ever connected with the Society. He replied that his highest aspiration in this matter was to awaken and develop a love for horticulture in the youth of the state. He had been actively engaged in the great work since July 4, 1812, and at the time of this meeting had not wearied of the well-doing for a period of sixty-two years! The hybrids of fruit gave him many new varieties of rare excellence. His flower-garden—always an object of interest—contained many specimens rare and beautiful, native and exotic. He succeeded in grafting the sweet bay on the magnolia and the rare flowers and fine fruits were his special care. He was a careful weather observer, and took accurate observations many years before the United States Weather Bureau charted the country. G. B. Brackett.

Landreth, David, founder of the oldest seedhouse in America, was born in 1752 at Haggerston, Northumberland County, England. He came to America late in the eighteenth century, making Philadelphia his home, and establishing there, in 1784, a nursery and seed business. Its location, on what was then known as High Street, is now covered by the building 1210 and 1212 Market Street. The raising of trees and production of seeds were conducted on land nearby, particularly on a tract at Twelfth and Filbert streets. This locality proving too contracted for the purpose, the nursery and seed grounds were removed in 1789 to the "Neck," then considered far out of town, the place chosen being not far distant from the site of the present arsenal.

The younger David Landreth was born in Philadelphia in 1802. When of suitable age he entered actively into his father's business, which had considerably extended in Philadelphia, while a branch house had been opened in Charleston, South Carolina. The young man's early duty was that of manager of this Charleston branch. Of the Charleston business, it will suffice here to say that it continued till the era of the Civil War, when it came to a sudden end by the act of the Confederate States District Court, which confiscated the real estate and merchandise alike, on April 22, 1862. Burnet Landreth.

Landreth, David, the younger, in 1828 succeeded his father as proprietor of the well-established and thriving business in Philadelphia, a business which was to remain highly prosperous for half a century afterward under his fostering care. His time, however, was not wholly occupied with the details of business, but was turned at an early age toward the literature of husbandry and to enterprises of public interest. Among the latter may be mentioned the Philadelphia Horticultural Society, of which, in 1827, he was one of the founders and a vice-president, and in 1828 was elected corresponding secretary, which office he held for seven years. At a subsequent date he was made president of the Philadelphia Society for the Promotion of Agriculture, and vice-president of the United States Agricultural Society, and became an active member of many other organizations.

His literary labors included the publication of the "Floral Magazine," started in 1832, and an advanced work for that period (see page 1559). At a later date he wrote much upon husbandry, his graceful style as a writer and his technical knowledge of the subject making his views of much value in the progress of the industry. He edited an American edition of George W. Johnson's "A Dictionary of Modern Gardening," a volume of 635 pages, published at Philadelphia in 1847.

In 1847 the Landreth nursery was removed to Bloomsdale, Bristol, Pennsylvania, where Mr. Landreth established what is believed to be the most complete seed-farm in the United States, and where he planted an arboretum which for years stood unequaled in this country in the development of its trees. He was an early breeder of the Channel Island cattle, then styled Alderneys, and was among the earliest manufacturers of mowing and reaping machinery. In 1872–3 he experimented in steam-plowing with a Scotch engine, and in the following year with an American engine. Subsequently, steam-digging and steam-chopping were experimented with at Bloomsdale, and many improvements produced in the machine-shop of that model farm. In early life he had lived amid the plantations of the Landreth nursery, one of the show places of Philadelphia—the site now marked by the Landreth School—and his virtues and character were those of one brought up in intimate contact with nature. Burnet Landreth.

Legaux, Pierre (or *Peter*), an early vigneron, who made one of the first attempts to establish the wine-grape and to make wine in this country. From his plantation at Spring Mill, near Philadelphia, Dufour secured vines for the great experiment in Kentucky (see Bailey, "Evolution Native Fruits").

The following information about Legaux is taken from Samuel Gordon Smyth, in the "Philadelphia Press," September 10, 1899:

"At the close of the Revolution there appeared among the French colonists in Philadelphia a man of superior talents and reputation, a political refugee who sought the hospitable shores of America to escape the impending doom which afterward swept over France. Pierre Legaux belonged to an aristocratic family of ancient lineage in Lorraine. By the scanty light thrown upon his early personal history we have been able to learn that he was born and educated in Metz; had been a counsellor in the Parliament there; a patron of the arts and sciences, member of several foreign academies, besides enjoying the personal friendship, favor and confidence of his sovereign Louis XIV. Under the régime, Legaux had filled positions in the Government with honor and distinction. Prior to the time of his escape to America, he had been in the diplomatic service of the king at one of the French West Indian Islands, and it was while there, through the intrigue and malevolence of his official superior, that he was forced to fly Guadaloupe to save his life. We begin to hear of his presence among his compatriots of Philadelphia, about 1786. He was spoken of as distinguished for his culture, scientific accomplishments and gentility. Mingling with the best society and finding friends among the men who were shaping the destinies of the nation, Legaux allied himself with the foremost, partaking actively in public affairs and appearing with the dignitaries in the social functions which enlivened the metropolis of America. Citizen Legaux became a member of the American Philosophical Society in 1787, at a time when his doing so would indicate the close touch he had with the ablest men of the day. It was in February, 1786, when Pierre Legaux bought from Augustine Prevost, a fine plantation on the Schuylkill River near Spring Mill. The property called 'Mt. Joy,' contained 206 acres.

"Noting the remarkable growth, productiveness and sweetness of the native grapes which thrived so luxuriantly on the warm banks of our forest-bordered rivers, and confident of a great destiny for this country in the cultivation of the grape, he argued that these latitudes compared favorably with those of sunny France and Italy in climatic and physical conditions favorable to its introduction and development. With this aim before him, he proceeded to demonstrate his theories. Importing a lot of the best varieties of stocks from Europe, even from distant Africa, he began the growing of vines on his plantation in 1787. He set out several acres on the warm southern slopes of the farm and gave most careful attention to their propagation. He talked learnedly about them to those whom he met and impressed his views upon the large circle of friends who gathered about and watched the progress of his new venture. As we glance over the pages of the newspapers of a century ago and read columns of matter concerning the vineyard, one naturally wonders at its vast importance. In fact, the 'Letters of a Farmer,' the news of the Old World by the latest packet and events transpiring within the borders of the infant Republic seemed subordinate to the paramount interests of the viniculturists."

The Pennsylvania Wine Company was organized to take over the enterprise, the stockholders comprising prominent men of the time. But the venture fell on bad ways. Dissensions arose, and litigation followed. "The devoted but aged Legaux, humbled and chagrined, became like a hewer of wood and a drawer of water where once he had been a gentle and influential host. In these latter days, the Sheriff came and went,—for the property was saved to the family by John Righter, Legaux's son-in-law, who by dint of picking up the shares here and there and buying off the claimants and so on, kept the estate intact. But before this had been accomplished Pierre Legaux, harassed, disappointed, and even robbed by his malicious servants, annoyed by the petty persecutions of neighbors, misunderstood and maligned, finally succumbed to the combination, and the spirit of the once cultured and ambitious Frenchmen passed into eternity, September 25, 1827." He was buried at Barren Hill, Montgomery, Co., Pa.

Lewelling, Henderson, pioneer nurseryman, was born in Salem, North Carolina, April 25, 1809, of Welch ancestry. At an early date he removed to Ohio and there founded the town of Salem; he removed to Indiana in 1831, founded another Salem, and to Iowa, 1839, there founding the town of Salem, and being of a roving spirit and a horticultural turn of mind, he left Salem, Henry County, Iowa, April 1, 1847. He joined one of the first colonies of emigrants to cross the Rocky Mountains to Oregon, where he left to posterity the name of "Salem," now the capital of that great state. True to his native inclinations, he took with him on his long journey westward from Salem, Iowa, by wagon-box and ox-team, in carefully prepared soil, 700 trees, vines and shrubs, representing a large number of leading varieties of apples and pears, a few varieties of plums and cherries and one Isabella grape-vine and one gooseberry plant. His scheme to establish a nursery in the densely wooded Northwest was so bold as to be audacious and the trip by ox-team across the plains, on a hitherto untraveled route, was long and arduous. He was advised repeatedly that his undertaking was hopeless. The trip through dry, thirsty land and over lofty mountain ranges was accomplished about the first of October, and Mr. Lewelling arrived at the Dalles with most of the trees alive. From that point he proceeded by water route to the town of Milwaukee, where he established the first nursery in the Pacific Northwest. George Himes, historian of Oregon pioneer days says it is an unquestioned fact that no other importation made by the early settlers did so much to add to the wealth and income of the people of Oregon as did Henderson Lewelling's traveling nursery. Ralph Geer, also a pioneer of 1847, in later years said: "That load of trees contained health, wealth and comfort for the old pioneers of Oregon. It was the mother of all the orchards west of the Rocky Mountains, and gave Oregon a name and fame that she never would have had without it. That load of living trees brought more wealth to Oregon than any ship that ever entered the Columbia River." Henderson Lewelling removed to California in 1854 and lived quietly until the termination of his life, December 28, 1878.

G. B. Brackett.

Lewelling, Seth, was born in South Carolina, March 6, 1819, and died at Milwaukee, Oregon, February 21, 1897. He was joint owner of an orchard on Cedar Creek, near Salem, Iowa, with his brother Henderson, and remained in charge of this orchard until 1850 when he crossed the plains to Oregon and became partner in the business of Lewelling & Meek, Milwaukee, Oregon. The nursery was not at first a success owing to the lack of stock on which to graft; but in 1850 seeds were brought to the territory by Mr. Pugh, and these were purchased by Lewelling & Meek and in 1851 they grafted 18,000 trees, and these apple trees sold readily for $1 apiece, and plum, cherry, pear and peach trees $1.50 each.

Seth Lewelling began his horticultural career with the beginning of the fruit industry in Oregon. He lived to see the pioneer cabins replaced by stately mansions; he lived to see the squatter claims become flourishing orchards and fruit-farms; he lived to see the populous East buy fruit from Oregon by trainloads and amounting to many millions of dollars; all this in fifty years. He was a horticulturist of the old school but he was not averse to teaching the younger men the road to success. He sold fruit in San Francisco in 1851 at $1 a pound, and it was then that the sister state of California realized that the gold in the mines was as nothing compared to the revenue she could reap from fruit orchards. She has steadily planted and is now the leading fruit-growing state in the Union. Mr. Lewelling was the originator of a number of fruits that have added materially to the wealth of Pacific coast horticulture; among these are the well-known Black Republican and Bing cherries and the Golden prune. He records the fact that he saw no fruit pests in Oregon until 1880; this is true of all new countries; insect pests and fruit diseases seem to follow colonization. Mr. Lewelling was a prominent figure in the fruit industry on the Coast, and he was one of the last survivors of the four pioneers who started the first orchards in Oregon.

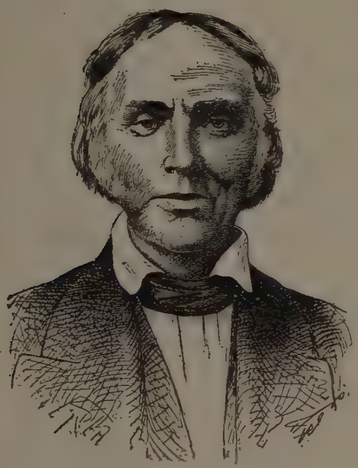
G. B. Brackett.

Lodeman, Ernest Gustavus (Fig. 1886), horticultural investigator and writer, was born in Neufchâtel, Switzerland, May 3, 1867, and died December 2, 1896, when connected with Cornell University, Ithaca, New York. His parents came to America when he was two years old, his father becoming, in 1870, professor of modern languages in the State Normal School of Michigan. The son entered the Agricultural College of Michigan, where he graduated in 1889. Modest and lacking in self-assertion, he needed encouragement and stimulus to

1886. Ernest G. Lodeman.

make a strong investigator and teacher. In a real estate venture in Florida, before his entering the Agricultural College, he became interested in agricultural problems and resolved to devote his life to them. In 1890 he undertook work as private assistant to the writer; and from this he became assistant and instructor in Cornell University. In the extension work amongst New York farmers he had charge of the investigations on grapes and strawberries. He was an originator of the spray-calendar idea. In 1896 he published "The Spraying of Plants," which is yet the fullest presentation of the subject. This was prepared after a most thorough traversing of the subject, both as author and experimenter, including a visit to Europe for the purpose of tracing the French history of the subject. He was an accomplished scholar, speaking German and French with fluency and possessing a working knowledge of other languages. His early death deprived American horticulture of a promising leader. L. H. B.

Longworth, Nicholas (Fig. 1887), (1783–1863) has been called the "father of American grape-culture." He was born in Newark, New Jersey. He early went to Cincinnati, then in the young and growing West, and engaged in banking and other business. He early became interested in agricultural affairs, and particularly in the grape. From John Adlum he received the Catawba, and became the means of making grape-growing a commercial success in the Ohio valley. He was a leader in the company of horticultural experts and writers which made Cincinnati famous in the middle of the century. Longworth was one of the first to perceive that many strawberries are infertile with themselves, and to suggest the planting of pollinizers, although the imperfect nature of the strawberry blossom had been known long before his time. He also introduced the Ohio Everbearing raspberry, the first improved variety of *Rubus occidentalis*. Longworth was a pioneer of horticulture in the expanding West, and more than that he was a guiding spirit in horticultural affairs of national importance. In 1846 he published a pamphlet on "The Cultivation of the Grape, and Manufacture of Wine. Also, Character and Habits of the Strawberry Plant." He also contributed a chapter on the strawberry to Buchanan's "Culture of the Grape." For further notices, see Hovey's "Magazine of Horticulture" 29:160, and Bailey's "Evolution of Our Native Fruits." The portrait in Fig. 1887 shows Mr. Longworth at seventy-four years of age. L. H. B.



1887. Nicholas Longworth.

Lord, Orville Morell, horticulturist and plum specialist, was born in the town of China, Wyoming County, New York, April 20, 1826, and died at Minnesota City, Minnesota, July 21, 1906. The Lord family moved to Lapeer County, Michigan, in 1842. After two years' training at a private school in Pontiac, Mr. Lord taught public school for four years in the country near his home. In 1852 he moved west with his family to Minnesota and was one of the first settlers in the Rollingstone Valley near Winona where he lived till his death with the exception of the years from 1861 to 1864 when he returned to a farm near Kalamazoo, Michigan. He was a member of the Territorial Legislature of Minnesota in 1853–4 and served in the State Legislature in 1873–4. He was active in many lines of public service throughout his life. In 1884 he became a member of the State Horticultural Society of Minnesota and was elected an honorary life member in 1899. He conducted a sub-experiment station for the society at his home for many years. He was considered one of the leading authorities in the Northwest on all lines of horticulture and enjoyed a national reputation as a plum specialist. He cultivated the well-known "Rollingstone" plum from a wild variety growing in the Rollingstone Valley. He also established several varieties of very good hardy apples. Mr. Lord was a lecturer on horticulture in the Minnesota Farmers' Institute for a number of years and also horticultural editor of "Farm, Stock and Home." He always carried on an extensive correspondence with other horticulturists all over the country. E. G. Cheyney.

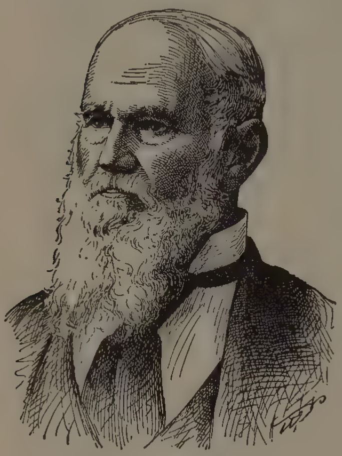
Lyman, Henry Martyn, pioneer horticulturist, was born at Easthampton, Massachusetts, September 13, 1828, and died at Excelsior, Minnesota, January 4, 1902. He was a descendant of Richard Lyman, who came to America in 1630 from England. Mr. Lyman received his education in the public schools and at Williston Seminary in Easthampton. His father died when he was fourteen years old and with the assistance of his mother and older brother he carried on the New England farm. Mr. Lyman came to Taylors Falls, Minnesota, in 1850. After remaining a year and a half, he returned to Massachusetts. In 1853 he came west again and landed at St. Anthony. He purchased an ox-team, a wagon and a little lumber and drove west to the site of the Lyman Homestead at Chanhassen, Carver County. He made this his home until his death in 1902.

Mr. Lyman was for years postmaster of one of the first post-offices in the county. He was interested in fruit-growing and planted the first apple trees in Carver County in 1853. These trees were not adapted to Minnesota and were winterkilled in 1856. In 1867 he planted more apple seed and from this lot came the "Lyman's Prolific" crab. From apple seed planted in 1876 and later came the Evelyn and other seedlings that are promising well for Minnesota conditions and are good keepers. Mr. Lyman was much interested in evergreens and early planted many varieties. He was one of the first settlers to realize their value as windbreaks and some excellent specimens are still to be found on the homestead.

In 1891 a trial station was located on his farm and is still in operation. He was treasurer of the State Horticultural Society in 1900. As a pioneer horticulturist, Mr. Lyman did very much to establish horticulture on a sound basis in Minnesota. Le Roy Cady.

Lyon, Theodatus Timothy (Fig. 1888), pomologist, was born in Lima, New York, January 13, 1813, and died in South Haven, Michigan, February 6, 1900. He was the son of a farmer. His school-going was very limited. In 1828, his parents went to the territory of Michigan, where he was employed in many pioneer pursuits, as farming, lumber-making, post-boy, tanner, merchant. He became more and more interested in farming, and in 1844 started a nursery on the farm at Plymouth, Michigan. He collected varieties from the local orchards, and found their names much confused. His interest was challenged, and gradually he became absorbed in a study of pomology, which in that day meant mostly knowledge of varieties. Articles on the varieties of Michigan apples in the "Michigan Farmer" attracted the attention of Charles Downing, and a correspondence and exchange of varieties resulted.

His name appears in the list of correspondents in the revised editions of Downing's "Fruits and Fruit Trees." For some years, Mr. Lyon was president of a railway company. In 1874, he moved to the "fruit-belt" of southwestern Michigan, where he became president of the Michigan Lake Shore Nursery Association, and where he lived until his death. The nursery association was not successful financially. In 1888, Mr. Lyon wrote a full (412 pages) and careful "History of Michigan Horticulture," which was published in the seventeenth report of the State Horticultural Society, a society of which he was president from 1876 to 1891, and honorary president until his death. In 1889, he took charge of the South Haven sub-station of the Michigan Experiment Station; and here, with his fruits and trees, he lived quietly and happily to the last.



1888. T. T. Lyon.

Mr. Lyon was one of the last of the older generation of pomologists. Like his colleagues, he was an expert on varieties. He was one of that sacred company which placed accuracy and cautiousness before every consideration of ambition or personal gain. His friends knew that he had not the temper of a commercial man. At one time it was said of him that he was the most critical and accurate of American pomologists. The fruit-lists of the Michigan Horticultural Society, his labors in revision of nomenclature for the American Pomological Society, and his various bulletins of the Michigan Experiment Station, show his keen judgment of varieties.

L. H. B.

McIntosh, John, originator of the McIntosh apple, was a farmer, born in 1777, near what is now known as the village of Dundela, in Matilda Township, Dundas County, Ontario, near the river St. Lawrence, and died in 1843. As a horticulturist he is noted only as the originator of the McIntosh apple. Little is known of his life, but the facts in connection with the McIntosh apple are as follows:

In 1796 he found growing in the clearing, a number of seedling apple trees. He took them home and planted fifteen or twenty of them in an orchard near his log house. One of these was named the McIntosh Red. The original tree lived until 1908. It was bearing apples until 1907, but its death was hastened by a hailstorm during that year. Ten years before it died it had been badly injured by a fire burning an adjacent building. The introduction of the McIntosh apple is mainly due to Allan McIntosh, the son of John, who was born in 1815 and died in 1899. He, during his long life, propagated and disseminated many trees, beginning the propagation in 1835. In 1912 a monument was erected on the old McIntosh homestead to commemorate the tree and its originator (see Vol. I, p. 317).

W. T. Macoun.

M'Mahon, Bernard (about 1775 to September 16, 1816), horticulturist, was born in Ireland and came to America, for political reasons, in 1796. He settled in Philadelphia, where he engaged in the seed and nursery business. He early began the collection and exportation of seeds of American plants. In 1804 he published a catalogue of such seeds, comprising about 1,000 species. He was the means of making many of our native plants known in Europe. He enjoyed the friendship of Jefferson and other distinguished men, and his seed store became a meeting-place of botanists and horticulturists. He was interested in all branches of horticulture. It is thought that the Lewis & Clark expedition was planned at his house. At all events, M'Mahon and Landreth were instrumental in distributing the seeds which those explorers collected. In 1806, he gave to America its first great horticultural book, "American Gardener's Calendar" which was long a standard cyclopedic work. The editor of the eleventh edition of this book (1857) makes the following reminiscence of M'Mahon:

"Bernard M'Mahon was no common man. He sought the American shores from political motives, as is understood. but what these were has not been determined; most probably it was necessary to fly from the persecution of government. He found American gardening in its infancy, and immediately set himself vigorously to work to introduce a love of flowers and fruit. The writer well remembers his store, his garden and greenhouses. The latter were situated near the Germantown turnpike, between Philadelphia and Nicetown, whence emanated the rarer flowers and novelties, such as could be collected in the early part of the present century, and where were performed, to the astonishment of the amateurs of that day, successful feats of horticulture that were but too rarely imitated. His store was on Second Street, below Market, on the east side. Many must still be alive who recollect its bulk window, ornamented with tulip-glasses, a large pumpkin, and a basket or two of bulbous roots; behind the counter officiated Mrs. M'Mahon, with some considerable Irish accent, but a most amiable and excellent disposition, and withal, an able saleswoman. Mr. M'Mahon was also much in the store, putting up seeds for transmission to all parts of this country and Europe, writing his book, or attending to his correspondence, and in one corner was a shelf containing a few botanical or gardening books, for which there was then a very small demand; another contained the few garden implements, such as knives and trimming scissors; a barrel of peas and a bag of seedling potatoes, an onion receptacle, a few chairs, and the room partly lined with drawers containing seeds, constituted the apparent stock in trade of what was one of the greatest seed-stores then known in the Union, and where was transacted a considerable business for that day. Such a store would naturally attract the botanist as well as the gardener, and it was the frequent lounge of both classes, who ever found in the proprietors ready listeners, as well as conversers; in the latter particular they were rather remarkable, and here you would see Nuttall, Baldwin, Darlington, and other scientific men, who sought information or were ready to impart it."

M'Mahon's name was given to west-coast evergreen barberries by Nuttall in 1818, and these shrubs are still known as Mahonias. See pp. 1511, 1518, 1521.

L. H. B.

Manning, Jacob Warren, nurseryman, was born at Bedford, New Hampshire, February 20, 1826 and died at Reading, Massachusetts, September 16, 1904. Until the age of twenty-one, he remained on his father's farm. At that time he went to Chelmsford, where he was engaged in farm, fruit and nursery work. In 1849, he became superintendent of the Winnesemitt Nursery at Chelsea, of which the proprietor was S. W. Cole. He remained here less than a year and until June, 1854, he was employed as a gardener in Dorchester, Massachusetts, Burlington, and Brattleboro, Vermont. At that time, he moved to Reading, where he established a nursery in his own name. He introduced many large and small fruits and ornamental trees and shrubs, prominent among which are the Rocky Mountain blue spruce (*Picea pungens*), the Cutter seedling strawberry, the Dracut amber grape, the John Sweet and the Granite Beauty apple. Mr. Manning made a specialty of evergreens and also established a large department of hardy herbaceous plants. He was a member of the Massachusetts Horticultural Society and the American Pomological Society for over forty years. He was also a member of the American Nurserymen's Association, the Massachusetts Fruit-Growers' Association and others. He served on many fruit committees, making exhibits in various parts of the country.

Manning, Robert (July 18, 1784, to October 10, 1842), was one of the most thorough and accurate of American descriptive pomologists. In 1823 he established his "Pomological Garden" at Salem, Massachusetts, for the purpose of collecting and proving varieties of fruits. At the time of his death this garden contained more varieties of fruits than had ever been collected in America. Pears were his specialty, but he had all the fruits which would thrive in his climate. These fruits numbered nearly 2,000 varieties, of which about one-half were pears. These varieties were gathered from all parts of this country, and also from Europe. The new pears of Van Mons, the Flemish scientist and propounder of a theory of plant variation (see "Survival of the Unlike," Essay V), were introduced largely by him. He also received valuable acquisitions from Robert Thompson, of the fruit department of the London Horticultural Society. In 1838, Manning published at Salem his "Book of Fruits, being a descriptive catalogue of the most valuable varieties of the pear, apple, peach, plum and cherry for New England culture." It also contained bush-fruits, grapes and hardy trees and shrubs. It was published as "First Series for 1838," which indicates that its author intended to issue other parts. All the descriptions were drawn from the fruits themselves. The book was illustrated. In this work he was assisted by John M. Ives; and Ives made a second edition of the work in 1844 under the title "The New England Fruit Book," and a third in 1847 as "New England Book of Fruits." At this day it is difficult to appreciate the work of a man like Manning. In those days, varieties were all-important. The scientific management of orchards had not yet arisen. Varieties were confused. Manning and his compeers opened the way for correct nomenclature and systematic pomology, and established the idea of testing varieties. His decisions on nomenclature were accepted as final. He was one of the founders of the Massachusetts Horticultural Society. For a reference to the position of Manning's work in our history, see page 1522; also Tilton's "Journal of Horticulture," 7, pp. 157, 158.

L. H. B.

Manning, Robert, Jr., was born at Salem, Massachusetts on July 6, 1827, and died on February 17, 1902. He and his brother, Richard, succeeded their father in the work of the "Pomological Garden." In 1869, he was appointed editor of Tilton's "Journal of Horticulture," which position he held until this magazine was discontinued in 1871. He was Secretary of the Massachusetts Horticultural Society for twenty-six years. Under his editorship, the "History of the Massachusetts Horticultural Society" was completed in 1880. For a fuller account, see the "Cyclopedia of American Agriculture," Vol. IV, p. 594.

Meehan, Thomas (Fig. 1889), writer, editor, state botanist, vegetable biologist, legislator and nurseryman, was born in London, England, March 21, 1826. He died at Germantown, Philadelphia, November 19, 1901. His father, Edward Meehan, was head gardener for Col. Francis Vernon Harcourt, at St. Clare, near Ryde, Isle of Wight, and there Thomas spent his boyhood. He was self-educated, acquiring Latin, Greek, French and the elements of botany by studying at night.

Mr. Meehan's first published paper was at the age of twelve on the production of double-flowered stocks from single. His first scientific discovery published was on "The Sensitive Nature of the Stamens of the Portulaca," at fifteen years of age. At the same age, he produced St. Clare, the first hybrid fuchsia known to the horticultural world. Numerous scientific papers followed, resulting in his being elected member of the Royal Wernerian Society of Edinboro, without making application or the Society being aware that he was a boy. Thomas Meehan became a student at Kew Gardens, and after graduation came to America, landing on his twenty-second birthday. Here he was employed by Robert Buist, Sr., in Philadelphia; was superintendent of Bartram's Gardens, and later gardener to Caleb Cope, Holmesburg, and while there flowered the *Victoria Regia*, the second time blossomed in America. In 1853, he established Meehan's Nurseries, afterward famous for their fine collection of American trees. He was sole editor of the "Gardener's Monthly" for the thirty years of its life, beginning in 1859 (p. 1559). He founded "Meehan's Monthly" in 1891, which survived him. For sixteen years he was agricultural editor of "Forney's Weekly Press," and at one time was agricultural or horticultural editor or regular contributor to more than half a dozen weekly and monthly papers and magazines. For thirty years he was the regular scientific editorial contributor to the "New York Independent." He was appointed State Botanist by Governor Hoyt and held that position until his death. For many years he was a member of the Board of Visitors of Harvard University. He was a prolific contributor to the publications of the Academy of Natural Sciences of Philadelphia, of which institution he was senior vice-president for twenty-three years; to the proceedings of the American Association for the advancement of Science, of which he was one of the early Fellows, and to the American Philosophical Society, the Pennsylvania Horticultural Society, the Pennsylvania Agricultural Society, in all of which he was an active member. He was recognized as the leading vegetable biologist of his day. He was the originator of the doctrine of evolution that self-sacrifice plays as important a part in nature and evolution as the struggle for existence and the survival of the fittest. For his scientific attainments in horticulture he was awarded the Veitch medal by the Veitch Memorial Fund of England, the third American so honored. He was the author of "Native Flowers and Ferns of the United States." He was elected a member of the Common Council of Philadelphia in 1882, and was reëlected biennially thereafter as long as he lived. As councilman, he inaugurated a movement for numerous small parks in Philadelphia. He was a member of the Germantown school board for eighteen years, and during that period secured the establishment of seven new schools, two exclusively for colored teachers. Other of his activities that may be mentioned are as follows: He

1889. Thomas Meehan.

discovered the Englemann Cañon in the Wasatch Mountains; in Alaska, he discovered the movements of plants in connection with the movements of glaciers; at the close of the war, he went South as a member of a committee to restore confidence and business relations between the two sections; he made what is supposed to be the first complete list of plants in Kew Gardens, over 1,600 plants being recorded; he was largely instrumental in the establishment of the Department of Forestry in Pennsylvania.

W. E. Meehan.
in Cyclo. Amer. Agric.

Miller, Samuel, pioneer plant-breeder, horticultural writer and plant-disseminator, was born at Lancaster, Pennsylvania, in 1820, and died at Bluffton, Missouri, in 1901. At Calmdale, Pennsylvania, he began the breeding of grapes, about the time of the introduction of the Concord. In 1867 he removed to Bluffton, Missouri. Here he brought together a notable collection of the various types and varieties of fruits and ornamentals. He did notable work in testing the adaptability of varieties to the central West, and his advice as to what sorts to plant in this section was sought by horticulturists, not only in Missouri but in surrounding states. Scores of plant-breeders sent him their new varieties to be tested, knowing that he would not only express a frank and honest opinion but that his judgment was sound, due to his extensive acquaintance with existing varieties. In addition to his work in introducing and testing varieties originated by others, he gave an important share of his time and energy to plant-breeding, most notably with grapes. No less than half a dozen varieties of his grapes have found a place in our pomological list, among them Martha, Black Hawk, Eva and Louise. He was an advocate of close breeding, for the reason, expressed by him, that his hybrids "broke up into many forms, giving uncertain results," while his close-bred seedlings, particularly of Concord and its descendants, "gave a large percentage of promising sorts." He originated the Captain Jack strawberry, which for two decades was largely used as a pollinator of Crescent in the berry fields of the West. During the later years of his life he was engaged in the amelioration of the native persimmon, of which he propagated a score of promising sorts, among them the Josephine.

For a third of a century Judge Miller was an officer of the Missouri State Horticultural Society, modestly declining to accept its presidency, often tendered him by its members. The annual reports of this organization contain many papers by Judge Miller. For a third of a century he also contributed regularly to the horticultural columns of "Coleman's Rural World." His writings are clear and sound. They were a distinct contribution to the horticulture of the author's generation.

J. C. Whitten.

Moon, James, and his descendants, have been of importance in the development of ornamental horticulture in America. Descended from English parentage, James Moon came to America in 1681 and purchased a tract of land near Morrisville. His grandson, also James Moon, took up a large tract in Bucks County, Pennsylvania, in 1749, and devoted a part of his time to the raising of fruit trees. Records of his transactions as early as 1769 are still in possession of the family, although no extended commercializing was attempted by any of the decendants until 1849, when Mahlon Moon purchased a tract near the Delaware River at Morrisville, Pennsylvania, and engaged in the nursery business, issuing his first catalogue in that year. With no desire for an extensive business, he laid substantial foundations for promoting a more general planting of ornamental trees and from the start largely specialized in these. He was the originator of the Numbo chestnut and introducer of *Exochorda grandiflora* and *Azalea amœna*, all of which he propagated very extensively. Mahlon Moon was born 1814 and died 1887.

Wm. H. Moon, oldest son of Mahlon Moon, was born in the nursery homestead of his father, Morrisville, Pennsylvania, 1849, and after completing his education continued for a time in the business of his father, but in 1872 established nurseries of his own in the same community, putting a strong spirit of commercialism into his business and from the first specializing in ornamental trees, especially in evergreens. He was probably one of the first persons to make a strong plea for more extensive use of this valuable class of trees and did more than any one man to promote new methods of culture and development into plants of individual merit and perfect outline. The business which he had thus started in a small way grew steadily through his persistent efforts until the time of his death in 1911. With his business activities Wm. H. Moon always found time to take a keen interest in affairs aside from his business. He was much interested in educational matters, giving his time and interest for their benefit. He was an active member of the Pennsylvania Horticultural Society and for seven years its president. In 1905 he was very active in founding the Pennsylvania Nurserymen's Association and was its first president. He was also a member of the National Nurserymen's Association and was one of the organizers of the Ornamental Growers' Association. His strong desire from the time of engaging in business was to put the utmost commercialism into horticulture and he was rewarded by the very extensive growth of his business.

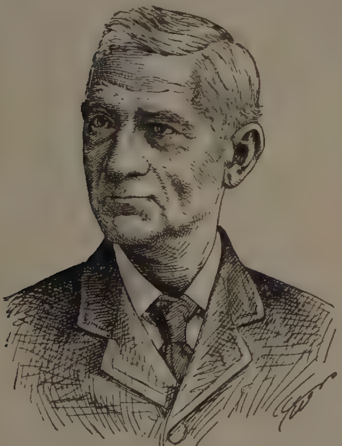
Samuel C. Moon (1854–1911), the second son of Mahlon Moon, continued the nursery business established by his father. He was a thorough lover of horticulture and his trees were his friends, his home being surrounded with many rare specimens planted by his father or collected and established by his own hands. His main development was in the line of ornamental horticulture, of which he was a rare student, contributing frequently to literature on the subject and occasionally addressing audiences on plant life. He was an authority on evergreens. Samuel Moon devoted many years to the best welfare of his community. He was active in educational and religious work. At the time of his death Samuel Moon was president of the Pennsylvania Nurserymen's Association.

Henry T. Moon.

Moore, Jacob, pomologist, was born at Brighton, New York, in 1836. His life-work was the development of new fruits, which he produced in large numbers by scientific plant-breeding. He was the originator of the Diploma currant, Red Cross currant, Hooker strawberry, Brighton, Diana-Hamburg and Moore's Diamond grapes, Barr Seckel pear and thousands of other fruits which have enriched the fruit-growers of America many thousands of dollars, but which brought him hardly a sufficient pittance to keep body and soul together. He also expended a competent private fortune in the work. He passed much of the late years of his life in trying to secure congressional legislation that would protect originators of fruit varieties, but his efforts were, unfortunately, without avail. Mr. Moore was a member of the Western New York Horticultural Society for nearly fifty years and was widely known among horticulturists. He died at Canandaigua, New York, in the winter of 1908.

G. B. Brackett.

Munson, Thomas Volney (Fig. 1890), nurseryman, grape-grower and author, was born September 26, 1843, near Astoria, Illinois, and died January 21, 1913. He received his education from the public schools of Illinois, the academy at Lewiston, Bryant-Stratton Business College and the University of Kentucky. In 1906 the University of Kentucky conferred upon him the degree of D.Sc. Dr. Munson located at Denison, Texas, where all his industrial, scientific and literary work was done. He established one of the most famous vineyards in the South, besides building up a reliable and well-known nursery business. He was the acknowledged authority on the native wild grapes of North America, and Bulletin No. 3, Division of Pomology, United States Department of Agriculture, "Classification and Generic Synopsis of the Wild Grapes of North America," which he wrote and which was published in 1890, is one of the most painstaking pieces of botanical work ever done in this country. It made the way for his later and greater work on "Grape-Culture." His horticultural and scientific work in hybridizing and perfecting the American Vitis won for him a diploma from the French Government in 1888, and the decoration of the Legion of Honor with the title of Chevalier du Merit Agricole for the aid he had rendered France in viticultural matters. He was also a member of the American Academy of Science, the National Agricultural Association of France, vice-president of the American Pomological Society, member of the American Breeders' Association, the Association for the Advancement of Science, and vice-president of the Texas Horticultural Association. In 1903–4 he was a member of the Texas World's Fair Association and the chairman of the committee of Texas Industrial Institutes. He was also a member of the jury of awards at the St. Louis Exposition in 1904 and an honorary member of the American Wine-Growers' Association and also a vice-president of the Society for Horticultural Science.



1890. T. V. Munson.

The most complete botanical display of the whole grape genus ever made was prepared by Dr. Munson and exhibited at the World's Columbian Exposition, Chicago, in 1893. This collection, now in the United States Department of Agriculture, will ever be a striking record of his wonderful patience, painstaking care and skill. His splendid book "Foundations of American Grape-Culture" is regarded as the most practical, complete and satisfactory account of the American grape yet issued, and is a lasting monument of his zeal, energy and scientific investigation. He knew the philosopher's stone, and left a last message to mankind to the effect that each individual should strive to be as useful and as free from blemish as a tree or a flower.

G. B. Brackett.

Nelson, A., pomologist, was born in Oneida County, New York, September 8, 1830, and died at Lebanon, Missouri, November 10, 1901. His early years were spent on a farm, where he always took great interest in horticulture. In 1858, he moved to Buffalo, where he engaged in the grain and coal business. After twenty-five years residence in that city, he went to Lebanon, Missouri, as an agent of the Ozark Plateau Land Company. Mr. Nelson was a very enthusiastic horticulturist, and was particularly interested in apples, being an authority on the varieties. He contributed to all the great fruit exhibits of the state, and for many years was treasurer of the Missouri State Horticultural Society. For portrait, and a fuller account, see forty-fourth report of Missouri Horticultural Society, of 1901.

Newman, James Stanley (Fig. 1891), was born December 11, 1835, in Orange County, Virginia. He passed his early life on the farm, working under the direction of his father, a highly educated and skilful agriculturist. In a private home school he was prepared for the University of Virginia where he studied four years, 1855–9. He served as a Confederate soldier in the Thirteenth Virginia Regiment. From 1865 to 1875, he farmed and taught; from 1875 to 1883 he was connected with the Georgia State Department of Agriculture, preparing publications, collecting agricultural statistics, and directing experiments. For nine years, he was professor of agriculture and director of the experiment station of the Alabama Polytechnic Institute, and for three years president of the Alabama State Agricultural Society. For over twenty-five years he was a life member of the American Pomological Society.

1891. J. S. Newman.

When Clemson College, at the old farm home of Jno. C. Calhoun, was organized in the early nineties, Colonel Newman was elected professor of agriculture and director of the agricultural department of that institution. He resigned in 1894, and ran a truck farm near Atlanta until July, 1897, when he was called back to Clemson College, where he served as professor of agriculture and director of the agricultural department and vice-director of the South Carolina Experiment Station, and (for three years) director of farmers' institutes, until his resignation in July, 1905.

Colonel Newman was the author of "The Southern Gardener's Practical Manual" and of several other useful works on agriculture and live-stock.

The last five years of his life were passed, as he had often expressed a wish they might be, in his own home, amid the fruits and flowers he loved so well. He was widely known in the South Atlantic States as a pioneer in the cause of the new agricultural education and uplift. He died at Walhalla, South Carolina, May 11, 1910.

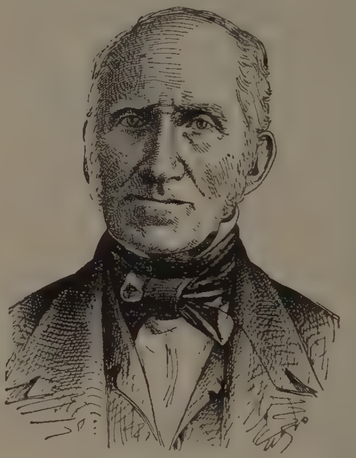
Wm. S. Morrison.

Olmsted, Frederick Law, landscape architect, was born April 26, 1822, at Hartford, Connecticut, and died August 28, 1903. He was educated in private schools, with private instructors in surveying and civil engineering. He was a special student at Yale College, a working student on crack farms, with seven years' farming on his own farms. He took several trips abroad for study of many parks and fine private places. He was superintendent and landscape architect of Central Park practically in partnership with Calvert Vaux, a young English architect who had been associated with Andrew Jackson Downing (in his time the leading landscape gardener of the United States) most of the time from 1857 to 1878. From 1865 to 1872, he was in partnership with Mr. Vaux and F. C. Withers, then alone, and later with various other partners. Some of his principal works were the parks of New York, Brooklyn, Buffalo, Chicago (South Parks), Milwaukee, Rochester, Louisville, Boston, Detroit, and many other cities and towns, the United States capitol grounds at Washington, World's Fair at Chicago, the great estate of George W. Vanderbilt at Biltmore, North Carolina, and the grounds of many public and semi-public institutions and of private individuals. He wrote a number of standard books of travel and he did a large amount of technical writing, most of which is scattered in the files of park commissions and other public and semi-public boards, and in periodicals, encyclopedias, and reports to owners of private estates. While he was familiar with the architectural and engineering, arboricultural and horticultural branches of his profession, and often designed the minutest details, yet in general, it was his practice himself to evolve the general designs for works of landscape architecture and to direct partners, assistants, superintendents, engineers and gardeners, working intimately and sympathetically with him, in the elaboration of general plans, working drawings, specifications and in superintendence. In this way he was associated in design with scores of architects, engineers, landscape gardeners and other technical men so intimately that in many cases it would be impossible to distinguish where the work of his assistants began and his ended. In the execution of his ideas in landscape planting, for example, he was assisted in the work on Central Park by Ignaz A. Pilat, and during the second period of his employment by W. L. Fischer, who also worked under his direction on the Boston parks; on the Brooklyn parks by O. C. Bullard; on the Buffalo parks by William McMillan; on the United States Capitol grounds by William Cogan, and on many other parks, grounds of institutions and of private individuals by Warren H. Manning, and so on. Mr. Olmsted took the greatest interest in and secured the adoption of what may be called the naturalistic style of planting, confining the use of the architectural style of planting almost invariably to gardens in close connection with important public or semi-public buildings or private residences. He may fairly be said to have been the originator in this country of the extensive use of shrubbery borders and masses as a main feature of landscape planting instead of planting individual shrubs as mere decoration. His influence throughout the whole country has been very great, as shown by the adoption by a host of imitators of the irregular, informal, picturesque or naturalistic landscape style, with the prevalence of curvilinear roads, walks, and the like. Some of these imitators often applied this style where it was distinctly inappropriate and where the formal or architectural style should have prevailed, as in the grounds of several universities and other semi-public institutions having usually large buildings. For portrait and further details, see "Cyclopedia of American Agriculture," Vol. IV, p. 601. JOHN C. OLMSTED.

Parsons, Samuel B., nurseryman, landscape gardener and author, was born in New York City, February 14, 1819, and died at Flushing, New York, on January 4, 1906. In 1899, he established a nursery with his brother Robert at Flushing, giving special attention to the introduction and propagation of ornamental trees and shrubs. They were the first nursery firm to introduce the Japanese maples and also to propagate rhododendrons in the United States. Mr. Parsons was an expert landscape gardener and the author of numerous essays on this and related subjects. He was also the author of a book on "The Rose, its History, Poetry, Culture and Classification." He was a charter member of the American Pomological Society and an honorary member of the Massachusetts Horticultural Society from 1856. For a fuller account and portrait, see "Cyclopedia of American Agriculture," Vol. IV, p. 602.

Pettit, Murray, fruit-grower, was born on March 13, 1843, at Saltfleet, Ontario, Canada, and died at Winona on March 3, 1910. On reaching manhood, he engaged in farming, in 1872 taking up fruit-growing as a specialty. He first took up the growing of peaches, and later branched into the culture of apples, pears, plums and grapes. He was particularly distinguished as a grape specialist, and was one of the first to plant Niagara grapes in Ontario. He carried on a number of experiments with grapes and other fruits and in 1894 was appointed director of the Experimental Station at Winona, which office he held until his death. Mr. Pettit was always among the first to take up new ideas, and was the third man in Ontario to use the spray-pump. He was very active in all the local fruit-growers' societies and a member of the Ontario Fruit-Growers' Association, having at one time served that body as president for a period of two years.

Prescott, Charles Rammage (Fig. 1892), pomologist, was born of Loyalist parents in Lunenburg County, Nova Scotia, the latter part of the eighteenth century. He was a successful merchant for many years in Halifax, but in 1812 closed his business and moved to the Annapolis Valley near Wolfville, Kings County, where he bought a farm and developed a fine estate. The old house still stands in good repair, though the gardens, orchards and vineyards, once the pride of the province, have largely disappeared. The work for which he is especially remembered is the introduction and dissemination of choice varieties of fruits. He is credited, among apples, with the introduction of Ribston, Blenheim, Gravenstein, Baldwin, Rhode Island Greening and Northern Spy, six out of the ten leading commercial varieties of the province today. The list of his introductions among other fruits is almost equally important. He was very generous with cions from his trees, and many of the earlier orchards of the province can be traced directly to his influence. He died in the autumn of 1859. F. C. SEARS.



1892. Chas. R. Prescott.

Prince, William, the second proprietor of the Prince Nursery at Flushing, Long Island, was born about 1725 and died in 1802. The nursery, which was perhaps the first large commercial one in America, was established about 1730 by his father, Robert Prince.* The Huguenots who settled at New Rochelle and on the north shore of Long Island brought with them a variety of French fruits, and the interest thus created in horticulture resulted in the establishment of his first nursery. For a number of years attention was confined chiefly to the fruit trees with which to stock the new country, and it was only when more settled conditions came that the culture of ornamental trees and shrubs was introduced. Under William Prince, the nursery grew rapidly in importance until the Revolution. A return of peace brought with it increased trade, to make good the depredations of the soldiery as well as to restock the orchards of those who for seven years had paid more attention to the science of war than to the pursuits of horticulture; and a catalogue of 1794 contains as many varieties of fruit as those of some nurseries of the present, apricots and nectarines, for example, each being represented by ten varieties.

Not only was everything of merit imported, but the origination of new varieties by a careful selection of seedlings was enthusiastically conducted. Two plums, still well known, date from this period, Prince's Yellow

---

*The founding of the establishment is usually attributed to William Prince, rather than to his father Robert. Page 1517.

Gage being originated in 1783 and the Imperial Gage in 1794. The "Treatise on Horticulture" mentions that in 1790 no less than twenty-five quarts of Green Gage pits were planted, from which seedlings were obtained of every color and shape, it being probable that the Washington plum was originated in that year. Before the death of this William Prince, the nursery business had been taken up by his sons, William and Benjamin; the former on new ground, called the Linnean Botanic Garden and Nursery, the latter at the original place, called The Old American Nursery. L. B. Prince.

Prince, William, third proprietor of the Prince Nurseries at Flushing, was born November 10, 1766, and died April 9, 1842. During his lifetime, the Prince Nursery was one of the centers of horticultural and botanic interest in America, and reached the height of its fame. He continued the work of his father in the introduction of all foreign trees and plants of value, the discovery of unknown American species and the creation of new varieties from seed. One of the trees introduced to great popularity by William Prince was the Lombardy poplar. In 1793, he bought additional property of 80 acres at Flushing. For fully fifty years, the nursery was conducted much less for profit than from a love of horticulture and botany. It was designed to contain every known kind of tree, shrub, vine and plant known to England and America that possessed any horticultural merit. The catalogues from 1815 to 1850 ranked among the standard horticultural publications of the country. The number of varieties of fruits cultivated seems scarcely credible in these days, when many nurseries are conducted solely for profit, and only the trees or plants which find a ready sale are propagated. In 1828, Mr. Prince wrote and published the "Treatise on Horticulture," which was the first work of the kind produced in America. L. B. Prince.

1893. Wm. Robert Prince.

Prince, William Robert (Fig. 1893), fourth proprietor of the Prince Nursery at Flushing, was born November 6, 1795, and died March 28, 1869. He inherited his father's love of botany and his great energy. He was connected with the American Institute, National Pomological Society, Massachusetts Horticultural Society, and many other important organizations, in whose transactions he took a prominent part. In 1830 he wrote, with the assistance of his father, the "Treatise on the Vine," a work of high importance. In 1831 he issued the "Pomological Manual" in two volumes, an important treatise on all fruits except apples. In 1846 he published the "Manual of Roses."

In his early manhood, Mr. Prince botanized through the entire line of Atlantic States in company with Professor Torrey, of Columbia, and Professor Nuttall, of Harvard. The oldest cedar of Lebanon in the United States, as well as the oldest Chinese magnolias, salisburias, Mt. Atlas cedars, paulownias and purple beeches are to be found today in the grounds of the Prince homestead, together with many other unique specimens. When the disease of the Irish potato caused a fear that it would have to be replaced by some other vegetable, he imported the Chinese yam or potato (*Dioscorea Batatas*), paying $600 for the tubers. About the same time he introduced sorghum, or Chinese sugar-cane. He was unwearied in his endeavors to promote silk-culture in the United States. He imported not only the silk-worms but the mulberry trees to feed them, and built a large cocoonery for their accommodation. L. B. Prince.

Pringle, Cyrus Guernsey (Fig. 1894), plant-breeder and botanist, was born in Charlotte, Vermont, May 6, 1838; died in Burlington, Vermont, May 25, 1911. He early devoted himself to horticultural and botanical lines of study and work. In the late sixties, he converted the home farm into a nursery, specializing on hardy bulbs, and had growing at one time over one hundred species and varieties of Iris and nearly all known species of Lilium. From the more usual types of plant-culture, he turned to the then relatively new field of plant-breeding. He first worked with the potato, later with the cereals, garden vegetables and fruits. During the decade 1869–79, he devoted practically all his attention to this work with rare skill, insight, and success. Among his many productions the following are notable (see article by Wm. Stuart in "The Country Gentleman," June, 1905): Potatoes—Snowflake (Early Rose × Excelsior, introduced 1873), Alpha (Early Rose × Sebec, introduced 1874), Ruby (Early Rose × White Peachblow, introduced 1875), Trophy (Early Rose × Excelsior). Tomato—Conqueror. Wheats—Defiance (Gold Drop × White Hamburg, introduced 1877), Grandee (Little Club × Lost Nation), Champlain (Black Sea × Gold Drop, introduced 1879), Green Mountain, Pringle's Nos. 5 and 6: Oats—Pringle's Progress, Pringle's Hulless, American Wonder.

1894. Cyrus Guernsey Pringle.

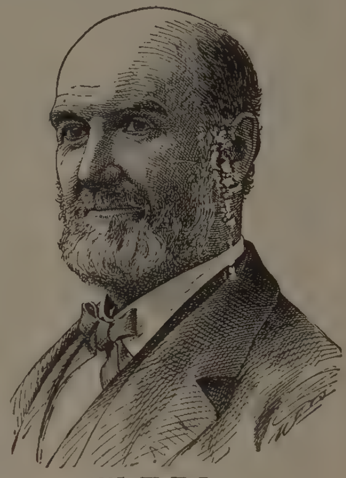
He was at the same time training and inspiring others in this work and generously distributing his hybridized potato seed. This early work entitles him to a leading place among the pioneer plant-breeders in America, and he would no doubt have continued in this field and become one of its greatest leaders had not family griefs driven him from home. He then, following the advice of Asa Gray, turned to botanical explorations. He secured many of the specimens for the Jesup collection of North American woods in the American Museum of Natural History, New York City, the finest collection of its kind in existence, together with much of the field data on the distribution of the forest trees for the "United States Census Report" of 1880. He had previously begun collecting Vermont plants for Dr. Gray and soon achieved a world-wide reputation as the "prince of botanical collectors." His journeyings extended from northern New England into Canada, across the Continent to the Pacific mountain regions and southward into Mexico. For twenty-six years, his work was chiefly in the latter country, continued under the patronage of the Mexican Government, the United States National Museum and other scientific institutions, and especially supported by Harvard University, on the botanical staff of which he was in 1893 appointed official collector by act of the Corporation. As a result of it, he not only enriched the leading herbaria of the world with extensive sets of choice specimens, especially of Mexican plants, but he amassed one of the largest and unquestionably the best private collections ever made. The Pringle Herbarium, of over 150,000 choice specimens, will remain his most fitting monument. During the last ten years of his life, he was Keeper of the Herbarium of the University of Vermont, and the Pringle Herbarium remains the property of that institution. L. R. Jones.

Purdy, A. M., horticulturist and author, was born in Macedon, Wayne County, New York, May 31, 1835, and died January 4, 1908. His father was a merchant in Macedon, but the son preferred outdoor life and in his boyhood was intensely interested in the raising of fruits and flowers. He was educated in the common school of Macedon Village, the Macedon-Center Academy, and at the Nine Partners Boarding School near Poughkeepsie, New York. In early manhood he went to South Bend, Indiana, where he engaged in growing fruits for about twelve years. Near the year 1865 he returned to New York state and purchased a farm on the Canandaigua road three miles south of Palmyra, and again engaged in growing fruits and nursery stock. On that farm over forty years of his life were spent, with the exception of three years' residence in Rochester. Soon after moving to New York State he began the publication of "The Fruit Record and Cottage-Gardener" and continued to issue the paper for over twenty-five years. He also published a small book entitled, "The Fruit Instructor." They were well received and many thousands sold. He also published as premiums three or four excellent fruit and flower chromos.

Mr. Purdy was a great worker, energetic, working early and late, and was a frequent contributor to agricultural and religious journals. He always took a great interest in politics and public affairs, and gave of his time and money for the advancement of the principles he thought to be right. He was a member of the Society of Friends (Quakers), and was recorded as one of their ministers. Wm. W. Miner.

Ragan, Reuben, pioneer nurseryman and pomologist, was born in Louisa County, Virginia, on October 6, 1793, and died August 19, 1869. Left an orphan at an early age, he was indentured by the Orphan's Court to Elisha Thomas, a Shaker, but the indenture was soon revoked. He was then apprenticed to a tanner. Through his early association with Edward Darnaby, a nurseryman, Reuben became interested in horticulture and determined to devote his life to this pursuit. He established a nursery in Indiana in 1820, from which he disseminated many hardy varieties of fruit around the state. Mr. Ragan was a charter member of the Indiana Horticultural Society and a leader in the pomological work of the state. For portrait and fuller accounts, see "Report of Indiana State Horticultural Society," 1870.

Ragan, William Henry (Fig. 1895), nurseryman, horticulturist and pomologist, was born on March 29, 1836, in Putnam County, Indiana. His father obtained land from the government by entry in 1822, and was widely known as a pioneer nurseryman, fruit-grower and horticultural enthusiast. William Henry Ragan grew to young manhood amid the primitive conditions of pioneer days, helping his father in the nursery work and engaging in the usual pursuits of the farm boy. His formal education was all received at the local log schoolhouse of the district. About the year 1860, he engaged in the nursery and fruit business on land he purchased near Fillmore. From 1869 to 1871 he was in the fruit business in Indianapolis, having formed a partnership with John Wineberger of that city. In 1871 he moved to Clayton, Indiana, and continued in the nursery business with his cousin, W. A. Ragan, as partner. In 1881 he became a trustee of Purdue University. In 1883 he was appointed superintendent of the experimental station at the University and for a few months later in the same year acted as superintendent of the campus and weather station. He left Purdue University in 1884 to accept the chair of practical horticulture and the position of superintendent of parks at DePauw University, Greencastle, Indiana, which was in that year reorganized from the Indiana Asbury Academy. He had disposed of his nursery business on leaving Clayton and purchased property at Greencastle where he lived until 1899, leaving to accept a position in the Department of Agriculture at Washington. He became assistant pomologist and expert in pomological nomenclature in the Bureau of Plant Industry and won a world-wide reputation, not only for his wonderful work in nomenclature, but for his numerous other written contributions and for his personal services in the advancement of horticulture. He continued his work with the Bureau of Plant Industry until his death, which occurred in Washington, D. C., August 6, 1909.



1895. W. H. Ragan.

During his later years, William Henry Ragan was one of the foremost and best-loved figures among the horticulturists of the country. He was one of the founders of the Indiana Horticultural Society and continued his active membership until his death. He was secretary of this organization from 1869 to 1882 with the exception of 1873, and again from 1891 to 1895 inclusive. He became a trustee of Purdue University for the second time in 1888 and served until 1892. He was superintendent of the Division of Pomology at the Cotton Centennial at New Orleans in 1884–5 and served as secretary of the Committee on Awards in the Department of Horticulture at the Columbian Exposition at Chicago in 1893. He was secretary of the Mississippi Valley Horticultural Society in 1883–4 and, when the name of the organization was changed, continued the same work for the American Horticultural Society until 1888. From 1897 until his death he was chairman of the Committee on Revision of Catalogue of Fruits for the American Pomological Society. As a member of the Indiana State Board of Agriculture from 1873 until 1882, and as president in 1880, he did much to foster the cause of fruit-growing in his native state. C. G. Woodbury.

Rand, Edward Sprague, lawyer and horticulturist, lost his life in the accident that befell the steamship "City of Columbus" in the early winter of 1884. Mr. Rand was for many years vice-president of the Massachusetts Horticultural Society. His exhibits of new and rare species of plants were of the best, and secured at considerable expense of time and money, an outlay he

made cheerfully for the good of horticulture. His collection of orchids was one of the largest and rarest of that time, and was donated to the Boston Botanic Garden. He was the legal counsel of the Massachusetts Horticultural Society, and an extremely prudent counsellor. To Mr. Rand's knowledge of books is due much of the success of the Society's excellent and voluminous library.
G. B. Brackett.

Rawson, Warren W., market-gardener, was born in Arlington, Massachusetts, January 23, 1847, and died August 9, 1908. He was educated in the schools of Arlington, Cotting Academy and Commercial College. He entered into partnership with his father in the market-gardening business in 1867, and in 1872 bought out the business, which he continued with success until his death. His plant is now the largest in New England devoted to market-gardening.
H. W. Rawson.

Reasoner, Pliny Ford, florist, horticulturist and nurseryman, was born at Princeton, Illinois, May 6, 1863, and attended the common and high schools of his native town. He was very fond of plants when quite young and had the largest and finest garden in his neighborhood. He went to Florida in 1882, settled near Manatee, devoting his life to collecting and cultivating tropical and semi-tropical plants. Not long after reaching Florida, he was joined by his younger brother Egbert N. Reasoner, and together they established the Royal Palm Nurseries under the firm name of Reasoner Bros. He began an extensive correspondence in many languages with directors of botanic gardens and plant-lovers and -growers in various parts of the world, and he introduced many hundreds of tropical and semi-tropical exotics. These were tested in the nursery and sent out to plant-growers in general. He was horticultural commissioner in permanent charge of the sub-tropical exposition at Jacksonville, Florida, 1887–8, and one of the three Florida commissioners at the Cotton States Centennial Exposition at Atlanta in 1888. He died at Manatee of yellow fever September 17, 1888, at the age of 25. At the time of his death, he was gathering together materials and notes with the intention of writing a great encyclopedia of tropical horticulture and floriculture. He had a genial, kindly disposition and his intense enthusiasm for the cultivation of plants was contagious. His plant importations may be found scattered all over the lower South in all the extensive collections of that region.
Chas. T. Simpson.

Rock, John (Fig. 1896), nurseryman, was born in Germany in 1836 and died August 8, 1904. His name was Johann Fels, which he translated into English on coming to America at the age of 15. He began in New York at once, at the bottom of the florist and seedsman business and rose slowly until 1861 when he volunteered (5th New York Zouaves) and fought till the close of the Civil War. Returning to horticulture, he settled in California in 1866 and built up one of the best and largest nurseries in the United States. He went to Europe many times, was in touch with nurserymen, botanists, horticulturists, all over the world, had extensive experiment grounds, tested thousands of new things, originated or brought into notice innumerable varieties of worth and at the time of his death, had 500 acres in nursery, at Niles, California. John Rock's scientific spirit, his wide and ever-increasing knowledge, his very high standards of business and his unselfishness made him during his long life the leader of Pacific coast nurserymen. He introduced more valuable plants and varieties to American horticulture than any other man of his period. His connection with Japan, India, Australia and with the great establishments abroad was close and constant. He did much to encourage men like Luther Burbank, and his collections were always at the service of students and the public.
C. H. Shinn.

1896. John Rock.

Roeding, Frederick Christian, nurseryman, was born in Hamburg, Germany, on December 31, 1824, and died July 18, 1910. His boyhood and early training were passed in Germany which fitted him for the successful commercial career which he subsequently achieved. He went to Chile and Peru in 1846. Three years later he left for California where he first went in for mining, but he soon abandoned this and became a member of the firm of Larco & Co., which afterward became known as the firm of R. Feurstein & Co., of which he was the senior member. He re-organized, and was one of the prime movers of the German Savings and Loan Society of San Francisco, and was vice-president and cashier for a period of twenty-five years. As early as 1869, his far-seeing judgment in the future of California's basic industry led him, with a number of other German associates, to buy 80,000 acres of land in Fresno County in the San Joaquin Valley. Shortly after this body of land was acquired, two sections, 1,280 acres, was deeded to the Southern Pacific Railroad Company for a town-site, by him and his associates, and it was on part of this land which comprises the best business and residential section of Fresno City today.

It was not until 1883 that he became actively engaged in horticultural work. It was in that year that the Fancher Creek Nursery was established. Possibly the chief event associated with his name is in connection with his work in the introduction of the Smyrna fig in California in 1886, and his untiring efforts in proving the necessity for caprification of this fig in order to produce it successfully. The first Smyrna figs, now known as Calimyrna, were produced through artificial pollenization in 1890, but it was not until 1901 that the first commercial product consisting of thirteen tons was placed on the market as a result of the pollenization of the little fig wasp, *Blastophaga grossorum*, which was imported the year previous with the assistance of the United States Department of Agriculture and established in some Capri fig trees on the Roeding place.

His name will always be associated with the City of Fresno, through his donation in 1903 of a piece of land for park purposes known as Roeding Park, consisting of 117 acres of ground in the immediate vicinity of the town.
George C. Roeding.

Rogers, Edward Staniford, grape-hybridizer, was born in Salem, Massachusetts, June 26, 1826, and died in Peabody, Massachusetts, March 29, 1890. He was the originator of forty-five seedling grapes known as the Rogers' hybrids. He was the first man to recognize the possibility of the probable value of *V. Labrusca* × *V. vinifera* hybrid varieties. For the female plant he used Carter or Mammoth Globe and fertilized with Black Hamburg and White Chasselas from an adjacent cold grapery; this work was accomplished in the summer of 1851, and the clusters were carefully inclosed in sacks. As a result of these pollinations, he secured about

150 seeds, which he planted in an old garden at Salem. He succeeded in fruiting forty-five seedlings, of which one to five were of Carter Black Hamburg; six to fourteen were Carter × White Chasselas; and the numbers fifteen to forty-five were of Hamburg parentage. In 1858 Mr. Rogers sent these varieties, under original numbers to various sections of the country for testing. He lacked room for a fair test in his small garden; the dissemination led to confusion, and the nurserymen to this day have never gotten the matter straightened out, so far as mere numbers are concerned. Mr. Rogers then gave the most promising varieties names, and these names were selected for persons noted for literary or scientific attainments or else for the towns and counties in his native state. Leading horticulturists of the day thought all the varieties should be named, as they possessed equal merit to a remarkable degree; but Mr. Rogers' preferred list is as follows: No. 1, Goethe; No. 3, Massasoit; No. 4, Wilder; No. 9, Lindley; No. 14, Gaertner; No. 15, Agawam; No. 19, Merrimac; No. 28, Requa; No. 39, Amini; No. 41, Essex; No. 43, Barry; No. 44, Herbert; No. 53, or No. 22, Salem, but not the Salem of the present day. There was a meritorious standard of excellence about these hybrids that Mr. Rogers was unable to obtain with subsequent crosses. These hybrids brought about a new era in grape-culture, and while not so intrinsically valuable as some later varieties, the work of Mr. Rogers, in one way and another, has added millions of dollars to the grape industry of America.

G. B. Brackett.

Sargent, Henry Winthrop (Fig. 1897), a son of Henry Sargent, an artist of reputation in his time and a grandson of Daniel Sargent, a Boston merchant of a prominent Massachusetts family, was born in Boston in 1810. Graduating from Harvard in 1830, Mr. Sargent studied law, which he never practised, and in 1841 purchased a small estate on the plateau above Fishkill Landing, New York, overlooking the Hudson River. Inspired and instructed by his neighbor, A. J. Downing, the landscape gardener, then at the height of his brilliant career, Mr. Sargent began to lay out a garden. This soon became distinguished for its beautiful distant views and vistas obtained by the removal of some of the native trees which originally covered it, for the arrangement of the shrubberies which made a piece of ground of only twenty-two acres in extent appear like a large park, and for the collection of conifers in which Mr. Sargent was particularly interested and which in its day was the most complete in the United States. Mr. Sargent traveled extensively in Europe for the purpose of studying the arrangement of country places, and to secure plants for his collections. As one of the results of these journeys he published "Skeleton Tours," a guide to the most interesting estates and gardens in England, with directions how to reach them and what to see in each. To the sixth edition of A. J. Downing's "Theory and Practice of Landscape-gardening," published in 1859, Sargent added an important supplement in which he described the making of Wodenethe, the name of his own place, and the estate in Wellesley, Massachusetts, of his relative, H. H. Hunnewell, to which was added an account of the many new trees and other plants which had first been tested in this country at Wodenethe; and for the seventh edition, published in 1865, he extended this supplement to include descriptions of the most recently introduced trees. For many years and during the life of its genial, accomplished and hospitable owner, Wodenethe was one of the best-known country places in the United States, and its influence in teaching correct principles of the art of garden-making and in increasing the love of country-life in the United States and the knowledge of trees was great and of lasting value. Mr. Sargent died at Wodenethe in 1882.

1897. H. W. Sargent.

C. S. Sargent.

Saul, John, nurseryman, was born at Castle Martyr, County Cork, Ireland, on Christmas Day, 1819, and died in Washington, D. C., on May 11, 1897. As he grew up, he was trained in the science of landscape gardening, and soon after becoming of age removed to the Isle of Wight, and subsequently to Bristol, England, in which place he was manager of extensive nurseries. Mr. Saul arrived in Washington in May, 1851, and was at once engaged by the Government to lay out the Smithsonian Grounds, Lafayette Square and other public squares, and also by W. W. Corcoran to plan the beautifying of Harewood Park. In 1852 he bought the property in which he spent the remainder of his life, 120 acres of which he set out in nursery stock, all kinds of evergreens, fruit, shade and ornamental trees and shrubs. He imported all new varieties from Europe as soon as they appeared. He equipped twenty greenhouses with large stock of new and rare plants, orchids and the like. He imported new plants from Europe as soon as they were offered for sale, and orchids from Africa, Mexico, Central and South America. He shipped plants to all parts of the country and some native plants to Europe.

He was appointed a member of the Parking Commission by Gov. Alexander R. Shepherd, and was reappointed by the District Commissioners after the office of governor was abolished, and was continued in office by each succeeding Board until his death, serving as chairman of the commission until the last.

B. F. Saul.

Saunders, William, nurseryman, landscape gardener and horticulturist, was born in St. Andrews, Scotland, in 1822, and died in Washington, D. C., September 11, 1900. He was educated in Scotland and England and spent some years in practical horticultural training at Kew Gardens. He came to America about the same time as Wm. R. Smith, former Superintendent of United States Botanic Gardens, 1848. He wrote many practical and timely articles on horticulture and kindred topics for the "Gardener's Monthly," "Hovey's Magazine," the "Horticulturist" and other periodicals. In 1854 Mr. Saunders entered into partnership in the nursery business, general horticulture and landscape gardening, with the late Thomas Meehan of Philadelphia. While there he originated and introduced fixed roofs for greenhouses which marked a great improvement over the movable sash formerly employed. He was a landscape gardener of note, and finished the planting of some of the national capital's park system which had been previously begun by Andrew Downing. He planned many parks through the eastern portion of the United States, among the most noted of which were Clifton, the country home of the late Johns Hopkins at Baltimore; Rose Hill Cemetery, Chicago; Oak Ridge Cemetery, Springfield, Illinois, and the National Cemetery, Gettysburg, Pennsylvania.

In 1862 Commissioner Newton appointed Mr. Saunders the Botanist and Superintendent of Horticulture of the newly created Department of Agriculture at Washington, D. C. The Department was at first called a Bureau and did not become a cabinet office until 1889. Mr. Saunders aided materially with advice and good work in shaping and developing the Department of Agriculture, and he was one of the ablest and most influential men the Department has ever had. He was one of the seven founders of the order of Patrons of Husbandry in 1867, and wrote its preamble and constitution. He was Master of the National Grange during the first six years of its existence.

He introduced into this country many fruits of economic importance. His knowledge of the flora of the world was extraordinary. He was one of the first to direct public attention to the proper environment for fruits; southern fruits for southern states, northern fruits for northern states. He introduced the hardy Russian apples for the extreme North in 1870. Mr. Saunders imported economic plants and trees of various kinds from almost every part of the globe. The *Poncirus trifoliata*, widely grown as a hardy stock for citrous fruits in the South and West, was obtained by him in 1869. He was endeavoring to secure a hardy type of Japanese orange, and the trees froze in transit from San Francisco to Washington, but the stocks survived, and these proved to be the now well-known *P. trifoliata*. He enlisted the aid of the late Prof. P. J. Berckmans of Augusta, Georgia, in the work of saving and perpetuating this stock. Mr. Saunders introduced the kaki or Japanese persimmon into this country and disseminated it widely in the South. His greatest success, however, was the introduction of the Bahia or Washington Navel orange, the seedless orange from Brazil that practically revolutionized the orange industry in California at that time, and brought in a subsequent revenue of millions of dollars.

G. B. Brackett.

Saunders, William (Fig. 1898), economic entomologist, horticulturist and the founder, and for quarter of a century Director, of the Experimental Farms of the Dominion of Canada, was born in England in 1835, and died in London, Ontario, September 13, 1914. He came with his parents to Canada when a boy of twelve. He started in business as a chemist and druggist and, as years went by, prospered to such an extent that he was able to devote his spare time and means to his favorite pursuits of botany, entomology and horticulture. He was one of the founders of the Entomological Society of Ontario, editor of the "Canadian Entomologist" for thirteen years, and author of the standard work, "Insects Injurious to Fruits," which is regarded as a classic by economic entomologists and fruit-growers.

Deeply interested in horticulture, he established a fruit-farm near London, and began his experiments in hybridizing and originating new varieties. His earliest efforts were devoted to the production of improved kinds of small-fruits, and he succeeded in obtaining satisfactory results with gooseberries, currants, raspberries and grapes, and also with roses and other ornamental shrubs. Many of his varieties are widely known and extensively cultivated, and his Emerald grape was considered the best of the Canadian sorts at the Colonial Exhibition in 1886. During this period he was an enthusiastic member of the Ontario Fruit-Growers' Association, which he was largely instrumental in maintaining during its day of small things, and of which he was president for some years.

In 1886 he was appointed Director of the Experimental Farms, and by his untiring energy, remarkable administrative ability, wide knowledge, both scientific and practical, long business experience and agreeable personality, he succeeded in establishing the chain of stations in all the provinces of Canada from the Atlantic to the Pacific, and prescribing for each its sphere of work in adaptation to its climate and local conditions. The immense value of the results obtained cannot be over-estimated; they will long continue to sustain the reputation of this man of genius to whose energy and ability they were due.

1898. William Saunders.

Among the many aspects of work which claimed his attention, horticulture continued to have a foremost place. For a long series of years Dr. Saunders carried on hybridizing experiments in order to produce apples hardy enough to withstand the rigors of the northwestern provinces, and of good size and quality. Taking the wild Siberian crab, which grows freely in Saskatchewan, as the female parent and crossing it with the hardiest Canadian and Russian apples, he gradually succeeded in obtaining hardy varieties nearly 2 inches in diameter which thrive in the far North and withstand a temperature of even 60° below zero. His efforts with cereals were equally successful; his Marquis wheat has proved to be the best variety in all respects of those grown in the western provinces, and has added millions of dollars to the value of their farm products. C. J. S. Bethune.

Sharp, Francis Peabody, the leading pioneer pomologist of New Brunswick, and perhaps of Canada, was born at Northampton, New Brunswick, in 1825, and removed to Upper Woodstock in 1844, at which place he resided until his death in 1903. Practically all of this time he was engaged in commercial orcharding, the growing of nursery stock, the testing of varieties and the creation of new fruits. He was the first man to introduce most of the standard varieties in the province—this being prior to 1858; obtaining cions from Canada, the United States and England. He devoted many years toward the production of varieties specially adapted to the New Brunswick climate and soil, the necessity of which he always emphasized. He early recognized the possibility of obtaining new and improved varieties from seed, and he imported seed from many sources for testing. In this manner he originated Sharp's New Brunswick apple, which many have regarded as being the Duchess of Oldenburg. Later, Sharp started to produce better varieties by hybridizing. Using the New Brunswick as one parent in most cases, he made upward of 2,000 crosses, originating a number of varieties of proved local worth, of which the best known is the Crimson Beauty. The date of the starting of this work does not seem to be definitely known but appears to have been about 1866. In an address given before the Farmers' and Dairymen's Association at Fredericton in 1896, Sharp stated that he and Peter M. Gideon were the first two men in America scientifically to hybridize the apple and pear. It would appear from this that Sharp was by many years the first man to begin this important work in Canada. Photographs and particulars are given in the report of the New Brunswick Fruit-Growers' Association for 1911.

A. G. Turney.

Shaw, Henry (Fig. 1899), founder of the Missouri Botanical Garden, popularly known as "Shaw's Gardens," was born at Sheffield, England, July 24, 1800, and died at St. Louis, Missouri, August 25, 1889. He came to the United States in 1819 and engaged in the hardware business until 1840 in St. Louis, where he continued to reside until his death. After retirement from active business he traveled for a number of years, and in 1849 laid out a modest garden about his country house in the suburbs of St. Louis, which, nine years later, he extended so as to include some forty-five acres, about half of this area constituting an arboretum.

By special act of the General Assembly of the state of Missouri, approved in March, 1859, Mr. Shaw was empowered to provide for the conveyance of his property, either during his life or after his demise, to trustees, for the perpetual maintenance of his garden as a scientific establishment. In 1885 he endowed a department in Washington University, known as the Henry Shaw School of Botany, and on his death left nearly all of his property, valued at some $5,000,000, to a board of trustees for the maintenance, improvement, and enlargement of the Missouri Botanical Garden.

Mr. Shaw, though not a botanist, was a lover of plants for themselves and a firm believer in their influence in molding desirable traits in human character. His garden was always open to visitors, among whom he particularly welcomed the self-respecting poor. Thirty years before his death he gave to the city of St. Louis a park site adjacent to his garden, which, like the latter, was improved under his personal supervision.

1899. Henry Shaw.

Special provisions in Mr. Shaw's will, aside from the general arrangements for the development of the garden—in details of which he allows his trustees a very free hand—are for an annual sermon "on the wisdom and goodness of God as shown in the growth of flowers, fruits, and other products of the vegetable kingdom;" premiums for an annual flower show; and two annual banquets, respectively for the trustees and gardeners of the institution. These banquets are the occasion for annual gatherings of men distinguished in botany and horticulture. See Vol. I, p. 531. Wm. Trelease.

Shepherd, Robert Ward, horticulturist, was born in 1848 and died at Montreal in November, 1912. For nearly forty years Mr. Shepherd was closely and prominently associated with the development of horticulture in the province of Quebec. Although he was for many years connected with the Ottawa River Navigation Company, his great love for horticulture was always evident and early in his life he planted extensive orchards at his home at Como on the Lake of the Two Mountains. His specialty was apples and he grew most of the varieties recommended for the province of Quebec and was continuously testing new sorts. His favorite variety was the Fameuse and he developed a high-class trade with this variety in England, shipping the fruit in special compartment cases. He unceasingly advocated the planting of Fameuse in the province of Quebec in preference to any other variety on account of its high quality. He originated the Rochelle apple, a promising hardy variety. As early as 1877 he was a director of the Montreal Horticultural Society and when the Quebec Pomological Society was formed in 1893 he was one of the most active in its organization. He was president of this Society in 1895 and again in 1906 and a director for many years, and on many occasions prepared papers for the meetings. He was Fruit Commissioner for the province of Quebec at the World's Fair in Chicago in 1893, and on three occasions was one of those who represented the province of Quebec at Dominion Fruit Conferences. Because of his prominence as a fruit-grower and his enthusiasm, he was on many other occasions appointed on important horticultural committees. W. T. Macoun.

Shepherd, Mrs. Theodosia B., and her husband were among the pioneers who left their homes in the Middle West to settle in California in the year 1873. Mr. Shepherd was an attorney and in this new country found little use for his services. His wife rose to the emergency and being of an artistic temperament, manufactured works of art out of the fauna and flora which she had collected. Her descriptive writings of flowers are among the finest this country has produced. The encouragement of Peter Henderson was incident to her entering this field. In 1881, she sent him a package of curiosities among which were a few choice flower seeds grown in the open. He wrote back saying that he believed California would be the great seed- and bulb-producing country of the world and that the conditions were ideal. Some of the products of her labor are a class of shrubby begonias of unequal vigor; a tea rose called "Oriole;" the perfection of cosmos; nasturtiums, California poppies and others were increased in size and beauty; the evolution of the petunia from a small flower of dull color to those of mammoth size and beautiful color. Mrs. Shepherd died September 6, 1906.

Shinn, James, pioneer nurseryman, was born at Salem, Ohio, September 29, 1807, and died October 29, 1896. He lived in several western and southern states and moved to California (from Texas) in 1855, establishing an orchard and nursery at Niles. He had studied and practised horticulture, had kept up a correspondence with specialists and at once took rank among the best-equipped men of the Pacific coast in his line of work. His introductions of Persian walnuts, Smyrna figs, Japanese plums and persimmons, the carob, Uinshiu oranges and many ornamentals were widely useful in the West and in the South as well as in California. His correspondence, and his newspaper writings, were extensive; he helped to found, and led in, the State Horticultural Society; his trials of new fruits and plants were extensive and thorough, and his coöperation with the experiment stations and with agricultural education was active. For more than forty years his influence broadened over the entire Pacific coast region. He was, with the exception perhaps of John Rock, the best known of California nurserymen. C. H. Shinn.

Smith, Andrew Murray, nurseryman, was born in Brandon, Vermont, September 24, 1832. The family removed to western New York in 1844, where Andrew made the best of his rather brief opportunities at a district school, and at Yabes Academy, Lockport. In 1852 Andrew engaged in work for Mr. E. Moody, near Lockport, and thus became acquainted with the nursery business, in which he afterward associated himself with Charles E. Woolverton, of Grimsby, Ontario, under the title of Woolverton & Smith. Finding a few old peach trees still bearing fruit in the garden of Dennis Woolverton about the year 1857, the firm decided to plant an orchard of six hundred trees, in addition to their nursery stock. The venture proved so successful that farmers about followed their example to such an extent that this Niagara District is now known as the "Peach Garden of Ontario." Mr. Smith continued the nursery business at Grimsby, Niagara and St. Catharines until the year 1900, when he retired at the age of seventy. He was one of the first members of the Fruit-Growers' Association of Ontario which was formed in 1859 and continued his active membership until his decease at St. Catharines, Ontario, October

19, 1910. For ten years, Mr. Smith was a director of the Association, of which he was made president in 1889, and a life member in 1900. No man in Canada has done more initiatory work in the development of the fruit industry of the province than A. M. Smith, insomuch that he has been called "the father of the commercial peach industry of Ontario." LINUS WOOLVERTON.

Smith, William Robertson, botanist, bibliographer, horticulturist, philanthropist, was born at the village of Athelstaneford, East Lothian, Scotland, March 21, 1828, and died July 7, 1912. He was educated in the schools of his native village. His earliest practical work in horticulture was done on the grounds belonging to the Earl of Wemyss, and later at Airthrie Castle and still later at Kew Gardens. On coming to America he located in Philadelphia, but was soon called to take charge of the work of the United States Botanic Gardens. These Gardens, nestling at the foot of the Capitol of the United States, were conceived by George Washington and are all that remains of his grand scheme of a national college and a national church. In 1822 a Botanical Society was formed and some planting was done on the drier portion of the marshy reservation. This society published what is now a very rare book entitled "Prodomus Columbiana," and it contained a list of the plants then in the District of Columbia. To this collection, John D. Breckenridge, prominent botanist of his day, added large quantities of plants of interest. The plants secured by the Wilkes' expedition around the world, placed in the Patent Office conservatory, were consigned to the United States Botanic Gardens in 1850 and Mr. Breckenridge was employed to give them expert attention, and with him was associated Dr. Asa Gray, botanist. All expenditures for the Gardens from 1851 to 1854 were paid from funds accredited to the Wilkes' expedition. William R. Smith became Superintendent of the Botanic Gardens in 1853. The times were troublous, and the first appropriation from Congress, including the pay of the superintendent and assistants was but $3,000. At this time the gardens were marshy, and ague-breeding. His first work was the filling in of 500,000 yards of soil. The development of the Gardens was necessarily slow and tedious, but in the period of Mr. Smith's tenure they were developed from a tiny flower-garden and botanical collection to the largest horticultural collection, public or private, in America. The work of Mr. Smith is well known to students of horticulture everywhere, and through this great work he came to be styled "the father of horticulture." G. B. BRACKETT.

Stark, James Hart, nurseryman and fruit-grower, was born July 30, 1792, in Hutchison, Bourbon County, Kentucky. He was the son of Capt. James Stark, who came to Hutchison, Kentucky, in 1785 from Virginia. The Starks were originally from Glasgow, Scotland, one brother settling in New England and the other in Virginia. Both were enthusiastic horticulturists. On a fly-leaf of one of the old law books of the Kentucky lawyer, preserved by the family, is a planting record of the family orchard which was probably the first orchard of grafted apples planted west of the Alleghanies.

For his military service in the war of 1812, Judge Stark was given script for land, in what is now Pike County, Missouri, where he located in 1815. Here, near the present site of Louisiana, he cleared a large tract of land, and went back to Kentucky for cions from the old family orchard in order to establish a nursery and orchard in Missouri. From this stock was started in 1816 the pioneer nursery west of the Mississippi. From the trees produced, the first commercial orchard in this section of the country, 45 to 50 acres in extent, was established. Northern buyers came each year and bought the crop of apples from this orchard, amounting annually to several thousand barrels. The nursery which he established in 1816 has been maintained and augmented by Mr. Stark and his descendants until today it is said to be the largest nursery in the world. Judge James Stark at first furnished trees for planting by his neighbors. In this way he began the dissemination of grafted stock of the best-known varieties of the time. The district in which he was located was also somewhat famous for wild plums, berries, grapes, and other fruit, and this stimulated in him an interest in the introduction and dissemination of new and superior varieties. The business which he established then has been responsible for the introduction into the Mississippi Valley and the far West of a very large number of the leading varieties of commercial fruits now being grown in western orchards.

Judge Stark in his day was regarded as the horticultural leader in his section of the country. That he knew thoroughly and loved his work, that he believed in it fully and got daily inspiration from it, is perhaps best emphasized by the fact that instead of his work dying with him, his inspiration, zeal and energy for it has been handed down through his descendants who have ably followed in his footsteps. J. C. WHITTEN.

Starr, Robert W., eminent fruit-grower of Nova Scotia, was born in 1830 at Starr's Point on the shore of Minas Basin. He came of an old United Empire Loyalist stock of Connecticut, a family which for four generations furnished militia officers. He was educated at Sackville Academy, New Brunswick. About the year 1860 Major Starr settled down to a life of fruit- and fruit-tree-growing, a line in which he became not only successful himself, but also of great service to his province. In addition to his vocation, he continued to serve in the militia as adjutant and later as major. In 1873 he was appointed Justice of the Peace for King's County. Major Starr was one of the original founders of the Nova Scotia Fruit-Growers' Association, which was started in 1863. Several times he was made president, and in 1873 was made a life member. In 1876 he was sent to the Centennial Exhibition, Philadelphia, with a large exhibit of Nova Scotia fruit, and in 1893 he was sent by his province to the World's Fair, Chicago, with a similar charge. Major Starr has been much in demand as a judge of apples, at exhibitions in Nova Scotia, New Brunswick, Prince Edward Island, and Ontario, and is considered the leading authority on the apple in the province of Nova Scotia. LINUS WOOLVERTON.

Stayman, Joseph, physician and pomologist, was born in Cumberland County, Pennsylvania, October 17, 1817 and died October 4, 1903. He studied medicine and in 1846 began to deliver lectures on scientific subjects. He engaged in the practice of medicine until 1858. In 1859, he established a nursery in Illinois but later in the year moved to Leavenworth, Kansas. For forty years, he engaged in experimental work on fruits, producing hundreds of hybrids and testing many varieties produced by others. The best known of his original productions are the Clyde and Stayman strawberries, the Stayman Winesap apple and the Ozark grape. Dr. Stayman was a charter member of the Kansas State Horticultural Society and was appointed as the Kansas delegate to the Centennial Exposition at Philadelphia in 1876.

Stiles, William Augustus, journalist, editor and park commissioner, was born March 9, 1837, at Deckertown, Sussex County, in northern New Jersey, and died October 6, 1897, in Jersey City. His grandfather settled on a farm near Deckertown in 1819, where his father, Edward A. Stiles, in 1833, founded Mount Retirement Seminary, a successful school of the highest rank during the following thirty years. William A. Stiles graduated at Yale in 1859 in a class which included many men who have since attained high rank in public affairs. Prevented from taking up the profession of law by constitutional weakness and defective eyesight, he found expression in diversified activities. He was in turn a teacher, assistant superintendent of public schools, surveyor on the Pacific coast, writer of political articles, secretary of the Senate of New Jersey, actuary of a life insurance company, and gauger in the New York custom house. During a long period of illness and almost total blindness he acquired systematic knowledge of plant-life from readings by his sisters, and this gave impulse toward subsequent study on broader lines. He brought together many rare and choice species of plants, and made interesting experiments on the farm. His articles in the daily press of New York on the various interests of country life attracted wide attention, and led to his appointment as an editorial writer of the New York "Tribune," a relation which continued throughout his lifetime. In 1883 he became agricultural editor of the Philadelphia "Press." Keenly interested in introducing scientific discoveries and improved methods into general practice, he established relations with the foremost agriculturists abroad and at home, and made his department a useful and valuable exponent of the best knowledge of the time. His masterly conduct of the page during the next five years set a high standard for journalism in this field, and established his reputation as a specialist in agriculture and cognate subjects. On the founding of "Garden and Forest" in 1888, William A. Stiles was invited to be the managing editor. For nearly ten years, to the close of his life, he devoted himself to this journal through vigorous editorial writing and management, and steadily maintained the high character of the most able and influential periodical in American horticultural journalism. For many years he rendered conspicuous service in working for the establishment of small parks easily accessible to the poor, and for the wise conduct of the larger parks and their preservation from invasion and despoilment. His special ability and influence received public recognition in 1895, when he was appointed a park commissioner of New York city, a position in which he rendered signal and valuable service until the time of his death.

M. B. Coulston.

Strauch, Adolph (Fig. 1900), landscape-gardener, was born in Prussia, August 30, 1822, and died at Cincinnati, Ohio, April 25, 1883. He began the study of landscape gardening at the age of sixteen, and perfected his knowledge and taste by travel and by working in many places, including Vienna, Schoenbrun, Luxemburg, Berlin, Hamburg, The Hague, Amsterdam, Ghent and Paris, spending several years at the latter place. In 1848 he went to London where he found employment in the Royal Botanic Gardens. In 1851 he came to the United States, landing at Galveston, Texas. From there he found his way to Cincinnati, and made that his home during the rest of his life. Mr. Strauch designed portions of the parks and many of the private grounds in Cincinnati. "Clifton" in that city, owed its beauty to his skill and good taste. Mr. Strauch's chief claim to distinction however, was in originating the park-like treatment of cemeteries. He developed his ideas in Spring Grove, which became the most beautiful cemetery in the world. His skill as a landscape gardener was called into requisition in many places, among which are included Buffalo, Cleveland, Toledo, Detroit, Chicago, Indianapolis, Nashville and Hartford. Frederick Law Olmsted used to say that when he needed inspiration he visited Spring Grove. Perhaps no man in the United States since A. J. Downing's time has done more for the correction and cultivation of public taste in landscape gardening than Adolph Strauch. He loved nature and tried to preserve her natural beauty. He was especially successful in grading land surfaces and securing beautiful rolling lawns, the shaping of which was done almost entirely by eye. He would say "When it pleases the eye, it is right." He also said that the lawn at the margin of a road should be tangent to the road's surface. He believed in the picturesque arrangement of trees and shrubs, and was very careful to use species that harmonize with each other.

1900. Adolph Strauch.

O. C. Simonds.

Stringfellow, Henry Martyn (Fig. 1901), was born at Winchester, Virginia, January 31, 1839, and died on June 17, 1912, at Fayetteville, Arkansas. He was graduated from William and Mary College in 1858. Later he attended the Virginia Theological Seminary at Alexandria, 1858–61. Enlisting in the Confederate Army in 1861, he soon rose from the rank of private to the rank of captain in the Ordinance Department. He studied law for several years. Much of his life was spent in Texas, where he was a pioneer in discovering and demonstrating the rich horticultural possibilities of the Gulf coast. He planted the first pear orchard on the coast in 1882. In 1884, he planted the first Satsuma orange trees in Texas—trees which he obtained from Japan. These plantings were at Hitchcock. In this single instance, he rendered American horticulture a service of vast importance, since during the past few years millions of Satsuma orange plantings have been made all along the Gulf coast and a vast industry has been created. By demonstrating the value of drainage and by other methods, he opened up the horticultural possibilities of the country lying between Houston and Galveston, previously regarded as waste land. This is now the pear and strawberry country of Texas. He was a frequent contributor to horticultural publications and the press. Some of his articles appeared in the press of some foreign countries. His book "The New Horticulture" was written and published at Galveston in 1896. Most notable of the new practices which he advocated in this book was a severe method of pruning young fruit trees, both tops and roots, preparatory to transplanting. This practice, which he called "close root-pruning," sometimes called the "Stringfellow method," again "stub-pruning," proved successful in sandy types of soil southward, and was adopted by many planters, especially of large peach orchards in the South.

1901. Henry M. Stringfellow.

Ernest Walker.

Strong, William Chamberlain, lawyer and pomologist, was born at Hardwick, Vermont, August 18, 1823, and died in New York City, May 11, 1913. He was a graduate of Dartmouth College and then entered the Harvard Law School, for several years practising law.

His interest in horticulture, however, caused him to give up law as a profession, and buy an estate at Waban, Massachusetts. He did much for American fruit-culture, especially the grape and pear industries, and he was regarded as a leader among old-line pomologists. He was also a benefactor in the introductions of new plants and trees from foreign countries. He was among the first to discover the immense floral value of rhododendrons and azaleas for the vicinity of Boston. He also did much to aid in the establishment of the Arnold Arboretum in 1872. Mr. Strong was the author of several valuable books on horticulture, some of which are "Fruit-Culture," "Grape-Culture," and the "Gardener's Manual." He was a member of the Massachusetts Horticultural Society, and in 1872 was sent to Paris as a delegate to the Pomological Congress. He was also a member of the American Pomological Society. G. B. Brackett.

Sturtevant, Edward Lewis, agricultural experimenter and writer, was born in Boston, Massachusetts, January 23, 1842, and died at South Framingham, Massachusetts, July 30, 1898. Though holding the degree of M. D. from the Harvard Medical School, Dr. Sturtevant never practised the profession of medicine, but devoted his life to agricultural work, first specializing on Ayrshire cattle, then on pedigree corn (Waushakum) and muskmelons (New Christiana), and afterward devoting particular attention to the modifications which cultivated plants have undergone as shown by such records as occur in the older books. In connection with these studies, Dr. Sturtevant brought together a rare collection of books dealing with plants published before the time of Linnæus (say 1753), which, with his index cards and herbarium, is now preserved at the Missouri Botanical Garden in St. Louis

As first director of the New York Experiment Station at Geneva, Dr. Sturtevant drew the broad plans on which the successful work of that establishment has been conducted and which have served largely as models for subsequently organized agricultural stations over the country. He was a man of active mind, and his career is suggestive of worthy work to an unusual degree. A biographic sketch and a list of his principal writings are printed in the "Tenth Report of the Missouri Botanical Garden." See also "Cyclopedia of American Agriculture," Vol. IV, p. 616.

Teas, John C., nurseryman, was born in Indiana, of Quaker parentage, in 1827 and died in Carthage, Missouri, July 29, 1907. At the early age of ten, he evinced his love of horticulture by planting and tending a garden of his own. He lived in Indiana until 1869, when he moved to Missouri, where he engaged in the nursery business. He originated and introduced many new and valuable novelties in all branches of horticulture, including pomology, forestry, floriculture and the like. He was one of the first to recognize the good qualities of *Catalpa speciosa* and at all times advocated the careful conservation of our natural forests, and the planting and care of new forests. Mr. Teas was an active member of the American Pomological Society and one of the organizers of the Indiana Horticultural Society. He was also a frequent contributor to the current literature of horticulture and pomology.

Terry, H. A., one of the pioneer horticulturists of the prairie region west of the Mississippi, was born in Cortland, New York, in 1826. At the age of ten he moved with his parents to Michigan, where he lived on a farm until he was nineteen. He then went west stopping a year in Illinois, reaching western Iowa in 1846. After that the most of his life was spent in the vicinity of Council Bluffs, not far from which city he established a nursery in 1857, where he carried on the work in breeding fruits and flowers which has given him special claim to recognition as one of the notable horticulturists of his region. In addition to carrying on his regular business as a nurseryman, he endeavored to add to the list desirable varieties which should be particularly adapted to his region at a time when such work was greatly needed. He named and distributed more than 100 of his seedling peonies, but doubtless his most important work was the origination of improved varieties of the native plum. Among the more important of his plum seedlings, classed under the americana species, are Admiral Schley, Bomberger, Bryan, Champion, Golden Queen, Hawkeye, Nellie Blanch, Terry and White Prune. Among his notable seedlings of the Munsoniana species are Downing, Hammer, Milton, all three from seed of the Wild Goose. Mr. Terry was long an active member of the State Horticultural Society and for several years was in charge of one of its trial stations. He died February 14, 1909. S. A. Beach.

Thomas, John Jacobs (Fig. 1902), one of the three pomologists who may be said to have created the science in this country (the others being Patrick Barry and the elder Downing), was born January 8, 1810, near the lake in central New York—Cayuga—on the shores of which he passed his life; and died at Union Springs, February 22, 1895. He was much more than a pomologist, his studies covering nearly every branch of rural industry except the breeding of live-stock, and his labors in the direction of adorning the surroundings of country life entitling him to rank in that department with the younger Downing. Two of his works, "Farm Implements and Machinery," and the series of nine volumes called "Rural Affairs," deal with the practical every-day matters of life on the farm in a manner at once pleasing and original, there being nothing that could quite fill their place in the whole range of our agricultural literature; and his incessant stream of inspiring editorials in "The Cultivator" and "The Country Gentleman" for nearly sixty years covered a wide and diversified range of rural topics. But pomology was his chief delight, and his fame rests mainly on his treatise on that subject, "The American Fruit Culturist." This immensely useful book first appeared, in 1846, as a paper-covered 16mo of 220 pages, with 36 wood-cuts, which must have been well received, inasmuch as a fourth edition (dignified with muslin binding) was published in the following year, and in 1849 another, enlarged to 424 duodecimo pages, and "illustrated with 300 accurate figures." This edition appears to have been reissued a few years later, with slight modifications and on larger paper, and was then called the seventh. Up to this time, changes in the work had been chiefly in the direction of natural growth. But horticultural knowledge was undergoing great modification; and in 1867, the public still calling for the book, it reappeared in different style, newly arranged and mostly rewritten, filling now considerably more than 500 pages, and accompanied by almost that number of illustrations. Rather unfortunately, this was called the "second edition," all its predecessors being probably regarded as different forms of the same book, while this was substantially new.

1902. John Jacobs Thomas.

The next edition, called the "eighth revised," appeared in 1875, and had nearly 600 octavo pages and over 500 engravings,—not to mention a colored frontispiece and highly pictorial binding; and this was followed, ten years later, by a revised reprint in plainer and more tasteful style, illustrated with the largest number of engravings yet reached, 519. This edition, the last issued during the life of the author, sold well, like all the others, and was long out of print and much sought for. A so-called "twentieth" edition, revised and enlarged by Mr. William H. S. Wood, with the assistance of a number of high authorities, appeared in 1897, and contains over 700 pages and nearly 800 illustrations. A "twenty-first" edition has also appeared.

Gilbert M. Tucker.

Thorburn, Grant (Fig. 1903), founder of the seed house of J. M. Thorburn & Co., New York, and horticultural author, was born in 1773 in Dalkeith, Scotland, and early came to New York to seek his fortune. His father was a wrought-nail maker, and the son engaged in the same trade in this country. He soon married, and his wife attended a store which he established in Nassau Street, near Liberty, for the selling of "tape, ribbons, thimbles, thread, scissors, and Oxbery's needles." The living-rooms were in connection. "A glass door opened opposite the fireplace, where she rolled the dumpling or broiled the steak with one eye, and kept a squint on the store with the other." The introduction of cut-nail machines deprived young Thorburn of his trade, and the establishment of a pretentious grocery business on the corner of Nassau and Liberty streets took away his customers. He therefore gave attention to other means of livelihood. The women of the city had begun to show a taste for flowers. These were grown in pots, and the pots were sold by grocers. In the fall of 1802, there being various pots in his stock, Thorburn thought to attract the attention of purchasers by painting the pots green. Four pots were first painted. They sold quickly. Then he painted twelve. They sold; and thus the pot business grew. Thorburn had been in the habit of buying his meat at the Fly Market, at the foot of Maiden Lane. In April, 1803, he bought a rose geranium there, thinking to be able by its means still further to advertise his pots. But the next day a customer bought both pot and plant; and Thorburn quickly returned to the market and bought two more plants. These sold; and thus the plant business grew.

1903. Grant Thorburn.

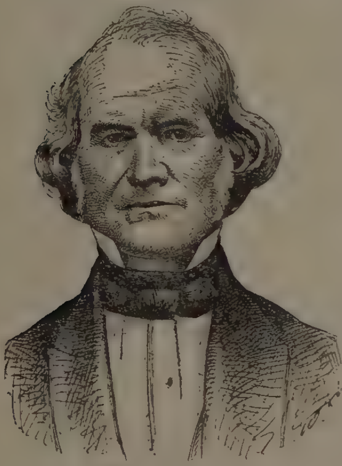
The man, George Inglis, of whom Thorburn bought the plants, was also a Scotchman, and it was soon agreed that one should grow the plants and the other sell them. But the customers also wanted to grow plants, and they asked for seed; and, as there was no seedstore in New York, it was arranged that Inglis should grow seeds also. This was in 1805; and in that year Inglis, as an experiment, had grown a lot of seeds. Thorburn bought these seeds for $15; and thus arose the first regular seedstore in New York, and one of the first in the United States.

The seeds and plants continued to sell, and Thorburn was obliged to import seeds. In 1805 or 1806 he obtained a catalogue of William Malcolm & Co., London, the first plant catalogue he had ever seen, and he then published one of his own. This led to more pretentious writing, and "The Gentleman and Gardener's Kalendar" was the first outcome. The third edition of this, in 1821, by "Grant Thorburn, Seedsman and Florist," contains the advertisment of "G. Thorburn & Son," dealers in seeds, implements and rural books.

Grant Thorburn was a prolific writer for the current press on a variety of topics, under the *nom de plume* of Laurie Todd. He was a unique character, and his history,—"mixed with much fiction," as he himself says,—was the basis of John Galt's tale in three volumes (London, 1830) of "Lawrie Todd, or Settlers in the Woods." Thorburn left a most interesting autobiography, which was published in New York in 1852. He died in New Haven, Connecticut, January 21, 1863, at the age of 90. The portrait in Fig. 1903 is reproduced from his autobiography. See p. 1518. L. H. B.

Thurber, George, botanist, naturalist and editor, was born in Providence, Rhode Island, September 2, 1821, and died at his home near Passaic, New Jersey, April 2, 1890. In his early years he devoted himself eagerly to the study of chemistry and natural sciences in general, but especially to botany, so that at an early age he was already well known as one of the most prominent botanists of the country. This brought him in close intimacy with John Torrey, Asa Gray, George Engelmann, Louis Agassiz and other eminent scientists, whose warm friendship he enjoyed until his death. In 1850 he obtained the appointment as botanist, quartermaster and commissary of the United States Boundary Commission for the survey of the boundary between the United States and Mexico. During the following four years his botanical work consisted mainly in the exploration of the native flora of these hitherto unknown border regions. His herbarium collected there comprised a large number of species new to scientists, some of which have been named after their discoverer, *Cereus Thurberi* being one of the most important; it is now cultivated for its fruit in the desert regions of North Africa. This historical herbarium formed the subject of Dr. Asa Gray's important work "Plantæ Novæ Thurberinanæ," published by the Smithsonian Institute. After his return to New York in 1853, Dr. Thurber received an appointment to the United States Assay Office, of which Dr. John Torrey was the assayer. In this position he remained until 1856, when owing to his strong sympathies with Gen. John C. Fremont, who was the first presidential candidate of the Republican party, he preferred to resign rather than sacrifice his principles. During the following three years he was connected with the Cooper Union and the College of Pharmacy of New York City as lecturer on botany and materia medica. In 1859 he was appointed professor of botany and horticulture at the Michigan Agricultural College, which position he held for four years. This position he resigned in 1863 to accept —on the urgent invitation of Orange Judd, the publisher—the editorship of the "American Agriculturist," which he held to within a few years of his death, when failing health prevented him from continuing his ardent labors. In this position he found his most congenial work and the real mission of his life, for which his previous training had fitted him so admirably. Few men have exerted so powerful and effective an influence on progressive horticulture and agriculture. The amount of his writings in the "American Agriculturist" during the twenty-two years of his connection with it was enormous, but as his name but rarely appeared with his articles it would be impossible to estimate the aggregate, yet whatever he wrote bore the stamp of accuracy of detail and naturalness of style. While in Michigan he revised and partly rewrote Darlington's "Agricultural Botany," which was published under the title of "American Weeds and Useful Plants." He wrote also the entire botany of Appleton's "New American Encyclopedia." An important part of his contributions to horticultural literature consisted in editing, revising and bringing out the horticultural and agricultural books of the Orange Judd Company. After the death of Dr. Torrey, he was elected president of the Torrey Botanical Club. He was also president of the New Jersey Horticultural Society; vice-president of the American Pomological Society for New Jersey; and honorary member of many scientific societies throughout the world.

F. M. Hexamer.



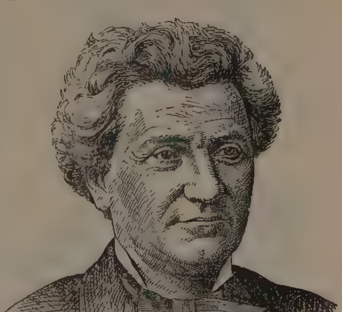
1904. Luther Tucker.

Tucker, Luther, (Fig. 1904), editor, was born at Brandon, Vermont, May 7, 1802, and died January 26, 1873. He was the founder of "The Horticulturist" and the proprietor of that valuable and unique magazine during the period of its greatest glory—from July, 1846, until the autumn of 1852. To A. J. Downing, however, belongs the credit for the distinguished interest and value of the magazine, as he conducted it according to his own ideas, with which the proprietor never interfered, the latter having indeed enough to do in putting it before the public with enterprise and vigor. It was issued simultaneously in Albany, Boston, New York and Philadelphia, with twenty-two special agencies at other points, including what was then the distant western town of Cleveland, Ohio, as well as Hamilton and Cobourg in "Canada West." Luther Tucker also founded, at Rochester, New York, October 27, 1826, the first daily paper published west of New York, "The Advertiser," which is still, under a slightly extended name, an influential journal; also at Rochester, January 1, 1831, "The Genesee Farmer," a weekly, the first agricultural periodical in the world written directly from the standpoint of practical experience. It has undergone some changes in name, as its scope extended far beyond the Genesee Valley, being now called "The Country Gentleman." It was published in Albany by the founder and his sons, from January, 1840, until July, 1911, when it was sold to the Curtis Publishing Company of Philadelphia. This is one of the ten American agricultural periodicals that were started before 1850 and outlived the nineteenth century, the others being these: "Maine (Kennebec) Farmer," 1839; "American (Boston) Cultivator," 1839; "Southern Planter," 1840; "Massachusetts Plowman," 1841; "Prairie Farmer," 1841; "American Agriculturist," 1842; "Southern Cultivator," 1843; "Indiana Farmer," 1845; "Rural World," 1848; "Ohio Farmer," 1848. It was natural that Luther Tucker should be interested in the New York State Agricultural Society, which he found at a low ebb on his coming to Albany, and of which, only a year later, he was the chief reorganizer, getting on foot the long series of annual fairs beginning in 1841 and still continued. He served the Society without any compensation or even reimbursement for his own expenses, for eleven years.

Gilbert M. Tucker.

Vaux, Calvert (1824–1895), an American landscape gardener, was born in London. Together with Frederick Law Olmsted he planned Central Park, New York, the prototype of large, accessible, nature-like city parks. The following account of his life-work is taken with slight changes from an obituary notice by Wm. A. Stiles in "Garden and Forest" 8:480. He had achieved success in architecture before the age of twenty-four, when he came to America as business associate of Andrew Jackson Downing. At the time of Downing's untimely death in 1854 the two men were designing and constructing the grounds about the Capitol and Smithsonian Institution, the most important work of the kind that had yet been attempted in America. Meanwhile, the gathering sentiment in favor of spacious and accessible city parks which had found expression in eloquent letters of Downing, at last secured, through legislative action, the purchase for a public pleasure-ground of the rectangular piece of ground now known as Central Park, New York. In 1858 the city authorities selected, out of thirty-three designs offered in competition for the new park, the one signed "Greensward," which was the joint work of Frederick Law Olmsted and Calvert Vaux, and Central Park as we know it today is the realization of this design in its essential features. It may be added that this "Greensward" plan, together with other reports on Central Park, on Morningside and Riverside Parks, in New York, on parks in Brooklyn, Albany, Chicago, San Francisco and other cities, both in this country and the Dominion of Canada, by the same authors, contain a consistent body of doctrine relating to public pleasure-grounds which is unique and invaluable. Calvert Vaux was a member of many important commissions, and he acted as landscape gardener for the Niagara Falls Reservation, but for more than thirty years his best work and thought were steadily given to the parks of New York City. He had the genuine creative faculty which gave the stamp of originality to all his work, and a severity of taste which preserved it from anything like eccentricity or extravagance. As a city official he was a model of intelligent zeal and sturdy integrity. Several times he resigned his lucrative position rather than see his art degraded, but he was always quickly reinstated by a demand of the people. See *Olmsted*, p. 1589; also *Landscape Gardening*, Vol. IV.

Wilhelm Miller.



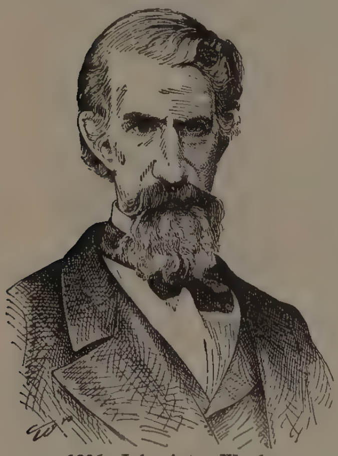
1905. James Vick.

Vick, James (Fig. 1905), seedsman and editor, was born at Portsmouth, England, November 23, 1818, and died at Rochester, New York, May 16, 1882. He came to America at the age of twelve, learned the printer's trade, and in 1850 became editor of the "Genesee Farmer," then published at Rochester by Luther Tucker and subsequently absorbed by "The Cultivator." In 1853 he purchased Downing's magazine, "The Horticulturist," and published it for a time, the editor being Patrick Barry. In 1860 Vick entered the seed business and his trade soon grew to large proportions. For about twenty years his name was a household word, being associated especially with flowers. In 1878 he founded "Vick's Magazine." Vick's personality was thoroughly amiable, and his letters in "Vick's Magazine" to children and to garden-lovers everywhere show the great hold he had on the hearts of the people.

Wilhelm Miller.

Warder, John Aston (Fig. 1906), physician, author, horticulturist and forester, was born at Philadelphia, January 19, 1812. His early life was spent in a suburban home, where he evinced a love of nature which he cherished through life. Bartram and Darlington were among his neighbors and he met in his father's house men like Audubon, Michaux and Nuttall. In 1830 his parents moved to Springfield, Ohio, where he helped clear up a farm and first became interested in agricultural sciences and comparative anatomy. He was graduated at Jefferson Medical College, Philadelphia, in 1836. He settled in Cincinnati in 1837 and began the active practice of medicine. He was early elected a member of the school board and did faithful service for many years, making it his business to travel through the eastern states and cities to study systems of teaching in order to introduce improved plans into the Cincinnati schools. He was actively interested in and a prominent member of the Cincinnati Astronomical Society, the Western Academy of Natural Sciences, the Cincinnati Society of Natural History. He was one of the founders of the Cincinnati Horticultural Society and the Wine-Growers' Association. He was also prominent in the old Cincinnati College and afterward in both the Ohio and Miami Medical Colleges. He was for many years president of the Ohio Horticultural Society and vice-president of the American Pomological Society. He was among the first to draw public attention to the improvement of public grounds, private parks and cemeteries. The present interest in landscape-gardening in this country is largely due to his efforts and writings. He was interested in establishing the famous Spring Grove Cemetery, one of the earliest and best of landscape or lawn cemeteries, and was one of the first residents of Clifton, whence he moved to a farm near North Bend, Ohio, formerly owned by President Harrison. There he spent most of his time in testing varieties of fruit and methods of culture, and prepared numerous practical papers for horticultural societies and other readers, and in fact established a private experiment station.

In 1850 he began the publication of the "Western Horticultural Review," which continued four years. In one number is contained the first description of the *Catalpa speciosa*, now recognized as one of the valuable forest trees. His report of the Flax and Hemp Commission, published by the Government in 1865, was the result of much patient study and investigation. "Hedges and Evergreens" appeared in 1858. "American Pomology—Apples," published in 1867, was the result of more than sixteen years of careful study, aided by hundreds of correspondents in various parts of the central states. It is still considered a standard authority on description and varieties of apples, containing a table of varieties and synonyms of over 1,500 names.



1906. John Aston Warder.

A report upon forests and forestry was the result of his visit to the World's Fair at Vienna in 1873, as United States Commissioner. In 1875 he issued a call for a convention at Chicago to form an American Forestry Society, which organization was completed at Philadelphia in September, 1876. The public was not yet impressed with the importance of the subject, but this pioneer association gave impetus to the plans for united effort. In 1879–80, with the approval of various societies, Dr. Warder memorialized Congress, asking for a commission for the study of forestry in Europe, but general interest was not thoroughly aroused until, largely through his efforts, the American Forestry Congress held its meeting in Cincinnati in April, 1882. He was honorary president of the Ohio State Forestry Society, prepared strong memorials to Congress on behalf of the forests and was shortly afterward appointed agent of the Department of Agriculture to report upon forestry of the northwestern states. He was devoted in his interest in all which concerns rural life and industry; his efforts had a great and marked effect on the horticulture and outdoor art of the great central states. Death ended an active and useful life July 14, 1883.

R. H. Warder.

Wellhouse, Frederick, judge and pomologist, was born in Wayne County, Ohio, November 16, 1828, and died at Topeka, Kansas, January 10, 1911. He was the son of a pioneer and received his early education in the typical log schoolhouse of the early days. He got his knowledge of farming at first hand on his father's 300-acre farm. In 1858 he published the "Indiana Farmer," a monthly agricultural paper, which he sold to his partner, J. N. Ray, in 1859, and afterward moved to Leavenworth, Kansas, and engaged in horticulture. During the Civil War, he was captain of the 19th Regiment, Kansas State Militia. He was elected county commissioner of Leavenworth County in 1861 by an almost unanimous vote. He was the Republican nominee for senator in 1864, but was defeated. He served two terms in the Kansas legislature, 1884–8. He was an active member of the State Horticultural Society, almost from its organization, and was for fifteen years its treasurer and four years its president. He represented the state of Kansas in the fruit display for the World's Columbian Exposition, Chicago, 1903, and did much pioneer work in Kansas horticulture in early days when that work demanded a leader. He represented the state's fruit industry at the various state fairs and the national expositions. He planted the largest commercial orchard in Kansas, and it was for many years the largest apple orchard in the world, an orchard of over 1,600 acres, that justly entitled him to the name of the "Apple King." This initial orchard was planted in 1876, and he added to the plantings for a number of years. In 1880 the yield from his orchard was 80,000 bushels besides the culls and it required 200 cars to ship them east. The yield for eleven years, from his first plantings, was 239,135 bushels which sold for $125,118.25. In the twenty-five years' trial of his commercial orchard he found Jonathan the most profitable variety; Missouri (Pippin) second best; Ben Davis third and Winesap fourth.

G. B. Brackett.

Wharton, Silas, pioneer nurseryman and pomologist, was born in 1775 in Bucks County, Pennsylvania. He removed to Waynesville, Ohio, about 1820 and was a celebrated pioneer nurseryman of that state. He grew Morello, May Duke and Carnation cherries, Red June, Summer Pearmain, Trenton Early, Summer Rose, English Hagloe, Ribston, Golden Pippin, Pennock and many other well-known apples. The Miami Valley and the neighborhood about Dayton, Ohio, are more indebted to Silas Wharton for intelligent fruit-growing at an early day, than perhaps to any other man. He was a warm friend of Coxe, the pioneer pomologist and author, and doubtless Coxe secured much valuable data from him for his book, "A View of American Fruits." Silas Wharton died in 1858.

G. B. Brackett.

White, William Nathaniel, teacher, horticulturist and editor, was born in Stamford, Connecticut, November 28, 1819, and died in Athens, Georgia, July 14, 1867. He was a graduate of Hamilton College, New York, a teacher in Atlanta, Georgia, and upon removing to Athens, he became one of the most prominent horticulturists of the South. He was a contributor to many agricultural and horticultural periodicals, both North and South, and before and during the time of the Civil War, he was owner and editor of the "Southern Cultivator." He was also author of "Gardening for the South," which book was published in 1856; after his death two more editions were published, one in 1867, and the last in 1901. His useful life was spent in the upbuilding of southern horticulture and agriculture. For a more detailed account see "Cyclopedia of American Agriculture," Vol. IV, p. 625.

T. H. McHatton.

Wilder, Marshall Pinckney (Fig. 1907), distinguished amateur pomologist and patron of horticulture, was born at Rindge, New Hampshire, September 22, 1798, and died at his home near Boston, December 16, 1886. His inherited love of country life soon showed itself, and at the age of sixteen he chose farm work in preference to a college course. At twenty-seven he moved to Boston, where he was long known as a prosperous merchant and president of many societies and institutions. His active interest in horticulture may be dated from 1832, when he purchased a suburban home at Dorchester, where he lived for more than half a century. His pear orchard at one time contained 2,500 trees, representing 800 varieties. During his life he tested 1,200 kinds of pears and in 1873 he exhibited 404 varieties. He produced several new pears. In 1844 he introduced the Anjou. He imported many fruits and flowers new to America, and from 1833 to the end of his life he was constantly contributing to the society exhibitions the products of his garden. He carried a camel's-hair brush in his pocket and was always hybridizing plants.

1907. Marshall P. Wilder.

He delighted in floriculture, and his camellia collection, comprising at one time 300 varieties, was the best in America. He raised many new kinds of camellias, though he lost 500 seedlings by fire. His *Camellia Wilderi* he sold to florists for $1,000. He also had a notable collection of azaleas. As early as 1834 he produced a double California poppy. Among the many floral novelties which he was first to import, cultivate or exhibit in America were *Diervilla rosea* (1851), hardy kinds of *Azalea mollis* (1874), *Cissus discolor* (1854), "the harbinger of the infinite variety of ornamental-leaved plants now so generally cultivated and admired," *Clematis cærulea* var. *grandiflora* (1841), *Lilium lancifolium* var. *album*, the first of Japanese lilies, *Gladiolus floribundus* (1836), and *Oncidium flexuosum* (1837), a plant of which bore ninety-seven fully expanded flowers and was the first orchid reported at any American exhibition. The Marshall P. Wilder rose makes his name familiar to a later generation.

Wilder's greatest services to horticulture were connected with the Massachusetts Horticultural Society and the American Pomological Society. Of the former he was a member for fifty-six years, and president from 1841 to 1848. He was one of the founders of the American Pomological Society, and with the exception of a single term was its president from its organization in 1850 until his death in 1886. He is counted one of the founders of the Massachusetts Board of Agriculture and of the Massachusetts Agricultural College, and of the United States Agricultural Society (1852). He was president of the last from its foundation until 1857, and from 1868 until his death he was president of the New England Historic Genealogical Society. At twenty-six he was a colonel, and in 1858, after declining the nomination four times, he was elected commander of the Ancient and Honorable Artillery Company. He was a trustee of the Massachusetts Institute of Technology.

In 1883 Marshall P. Wilder urged upon the American Pomological Society the necessity of a reform in the nomenclature of fruits. He took an active part in the great work that followed.

In the early days when the conflicting interests of the Massachusetts Horticultural Society and the Mount Auburn Cemetery required separation, he was an important factor in solving the complicated and delicate problem. The settlement of this difficulty laid the foundations of the wealth of the Massachusetts Horticultural Society.

At his death he left the American Pomological Society $1,000 for Wilder Medals for objects of special merit and $4,000 for general purposes. He left the Massachusetts Horticultural Society $1,000, to encourage the production of new American varieties of pears and grapes.

Wilhelm Miller.

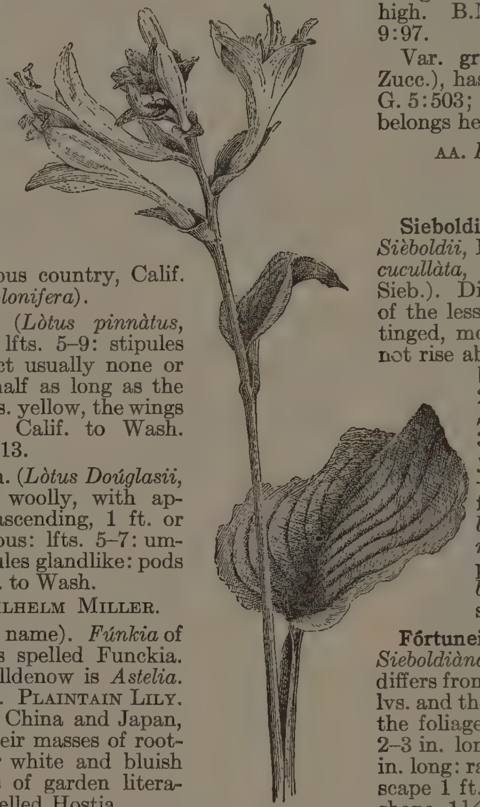
Woolverton, Charles Edward, pomologist, and nurseryman, was born in Grimsby, Ontario, August 22, 1820. He was the youngest son of Dennis Woolverton, of New Jersey, who settled on a farm of 400 acres on the south side of Lake Ontario, in the Niagara district in 1798. Here Charles became accustomed to every department of work both in farm and orchard. He was educated at Madison (now Colgate) University, and in 1846 settled upon a portion of the old homestead. In 1856, in company with A. M. Smith, he devoted a considerable portion of his farm to nursery and orchard, in which business he was quite successful, distributing fruits and fruit trees throughout a considerable portion of Ontario, Quebec and Nova Scotia. At Grimsby, he planted the first large commercial orchard of peach trees and proved the adaptability of the soil and climate of the Niagara district for the production of peaches and sweet cherries. In company with Messrs. Beadle, Smith, Arnold, Judge Logie and several others, Mr. Woolverton was instrumental in the formation of the Fruit-Growers' Association of Ontario, which afterward reached a membership of over 5,000, and was the chief agent in the encouragement and development of horticulture in southern Ontario. He died in August, 1900.

Linus Woolverton.

HOSÁCKIA (David Hosack, professor of botany and medicine in New York; author of "Hortus Elginensi," 1811; died 1835). *Leguminòsæ.* Herbaceous plants, three of which have been advertised by collectors of northwest American plants.

The genus contains about 40–50 species, all American and mostly confined to the Pacific slope: herbs or rarely subshrubs: lvs. pinnate, with 2 to many lfts.: stipules minute and gland-like, rarely scarious or leafy: fls. yellow or reddish, in axillary umbels which are peduncled or not.—The genus is closely related to Lotus, with which some authors unite it, but the calyx-teeth are shorter than the tube: keel obtuse: lvs. usually with numerous lfts., none of which is like stipules, while Lotus has calyx-lobes usually longer than the tube, a rostrate keel and 5 or 4 lfts., of which 2 or 1 are stipule-like. The two species first mentioned belong to a section in which the pods are shortly acute, linear, many-seeded, straight, glabrous: fls. and fr. not reflexed: peduncles long. The third species belongs to a section in which the pods are long-attenuate upward, incurved, pubescent: peduncles short or none: fls. and fr. reflexed. See *Lotus*.

crassifòlia, Benth. (*Lòtus crassifòlius*, Greene). Stout, 2–3 ft. high, nearly glabrous: lfts. 9–15, thickish: stipules scarious, small: bract below the umbel: calyx-teeth short: pod thick: fls. greenish yellow or purplish. Dry places in mountainous country, Calif. B.R. 1977 (as *H. stolonifera*).



1908. Hosta plantaginea. (×⅙)

bícolor, Douglas (*Lòtus pinnàtus*, Hook.). Glabrous: lfts. 5–9: stipules scarious, small: bract usually none or small: calyx-teeth half as long as the tube: pod slender: fls. yellow, the wings often white. Cent. Calif. to Wash. B.R. 1257. B.M. 2913.

decúmbens, Benth. (*Lòtus Doúglasii*, Greene). Silky or woolly, with appressed hairs: sts. ascending, 1 ft. or more long, herbaceous: lfts. 5–7: umbels less dense: stipules glandlike: pods pubescent. N. Calif. to Wash.

WILHELM MILLER.

HÒSTA (personal name). *Fúnkia* of Sprengel, sometimes spelled Funckia. The *Funckia* of Willdenow is *Astelia*. *Liliàceæ*. DAY LILY. PLAINTAIN LILY. Hardy perennials of China and Japan, much planted for their masses of root-leaves and for their white and bluish flowers; the funkias of garden literature. Sometimes spelled Hostia.

Herbs, forming stools or clumps: lvs. petiolate, ovate or lance-ovate, prominently several-ribbed, those on the flowering sts. smaller and becoming bract-like: fls. in terminal racemes or spikes, white or blue; perianth funnelform, 6-parted and more or less irregular, the lobes not widely spreading; stamens 6, the filaments filiform, the anthers long-oblong and versatile: pod oblong and angled, many-seeded, splitting into 3 valves; seeds flat and black, winged at the apex.—Species about 10. In cult., the synonymy seems to be much confused.

The hostas are hardy and of the easiest culture. Their dense stools or clumps of foliage are in place along walks or drives and in the angles against buildings. A continuous row along a walk gives a strong and pleasing character. Make the soil rich and deep. The clumps improve with age. The large-leaved kinds grow vigorously in moist, shady places. Of some varieties the leaves are strikingly variegated. They bloom in summer. Foliage is killed by frost. Propagation is by dividing the clumps; some species produce seeds freely, and seedlings can be grown readily if seed is sown as soon as ripe.

A. *Fls. white, ascending; fl.-bract very large, with a smaller one inside.*

plantagínea, Aschers. (*Hemerocállis plantagínea*, Lam. *H. álba*, Andr. *Fúnkia subcordàta*, Spreng. *F. álba*, Sweet. *F. liliiflòra*, Hort. *F. japónica*, Hort., at least of some. *F. cordàta*, Hort., not Sieb.). Fig. 1908. Lvs. large, broadly cordate-ovate, with a short, sharp point, green, many-ribbed: fls. large, 4–6 in. long, with an open bell-shaped perianth, waxy white, the base of the tube surrounded by a broad bract; spike short, the bracts very prominent.—The commonest species in old yards, and an excellent plant. The fls. have an orange-like odor. Clumps of foliage grow 12–20 in. high. B.M. 1433 (as *Hemerocallis japonica*). Gng. 9:97.

Var. **grandiflòra,** Hort. (*F. grandiflòra*, Sieb. & Zucc.), has very long and large fls. G.C. III. 4:153. G. 5:503; 23:591. *H. macrántha*, Hort., probably belongs here.

AA. *Fls. blue or lilac, more or less inclined or nodding; bract 1.*

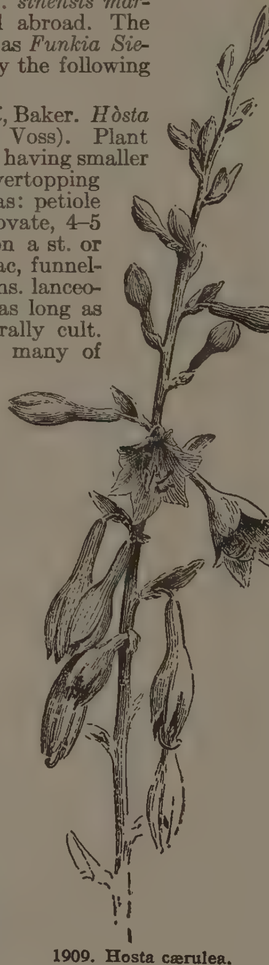
B. *Lvs. glaucous.*

Sieboldiàna, Engler (*Fúnkia Sieboldiàna*, Hook. *F. Sièboldii*, Lindl. *F. glaùca*, Hort. *F. sinénsis*, Sieb. *F. cucullàta*, Hort. *F. glaucéscens.* Hort. *F. cordàta*, Sieb.). Differs from the last in the metallic blue color of the less cordate lvs., in the inclined bluish or pale-tinged, more slender-tubed and smaller fls. (which do not rise above the foliage), and in having only 1 small bract at the base of the fl. B.M. 3663. B.R. 25:50. L.B.C. 19:1869 (as *Hemerocallis Sieboldtiana*). G. 10:387; 13:3. G.C. III. 38:94. There is a form with the body of the lf. yellowish white and the edge green. Lowe, 34.—Lf.-blade and petiole each 1 ft. long, the foliage therefore overtopping the fls. *F. Sieboldii elatior* and *F. sinensis marmorata*, are offered abroad. The plant usually cult. as *Funkia Sieboldiana* is probably the following species.

Fórtunei (*Fúnkia Fórtunei*, Baker. *Hòsta Sieboldiàna*, var. *Fórtunei*, Voss). Plant differs from *H. Siéboldiana* in having smaller lvs. and the racemes much overtopping the foliage, as in other hostas: petiole 2–3 in. long; blade cordate-ovate, 4–5 in. long: raceme ½ft. long on a st. or scape 1 ft. long; fls. pale lilac, funnel-shape, 1½ in. long, the segms. lanceolate and ascending and half as long as the tube.—Excellent. Generally cult. as *Funkia Sieboldiana*, and many of the pictures of that name, probably belong here, as, apparently, Gn. 38, p. 79; A.G. 11:157; A.F. 6:322. It is probable that the garden synonyms cited under *H. Sieboldiana* are usually applied to plants of *H. Fortunei*. A var. **gigantèa** is offered, with lvs. and fls. much larger than in the type. Vars. **robústa,** and **argénteo-variegàta,** are also listed abroad.

BB. *Lvs. green.*

cærùlea, Tratt. (*Fúnkia cærùlea*, Sweet. *F. ovàta*, Spreng. *F. lanceolàta*, Sieb.). Figs. 1909, 1910. Lvs. broad-ovate, 5–10 in. long and half as wide, usually tapering to the petiole, but sometimes subcordate: raceme long and lax; fl. with a short, slender tube and suddenly expanding into a bell-shape, 1½–2 in. long, nodding, deep blue. B.M. 894



1909. Hosta cærulea. (×⅙)

(as *Hemerocallis cærulea.*) Mn. 1, p. 73.—The commonest blue-fld. species. *Fúnkia marginàta,* Sieb., is a form with white-bordered lvs. There is also a yellow-variegated form.

lancifòlia, Tratt. (*Fúnkia lancifòlia,* Spreng. *F. japónica,* Hort., of some). Lvs. lanceolate to narrowly ovate-lanceolate, the blade 6 in. or less long and 2 in. or less wide: raceme lax, 6–10-fld., on a tall, slender st.; fls. 1½ in. or less long, the tube slender and gradually enlarging upward, pale lilac. Var. **álbo-marginàta,** Hort. (*Fúnkia álbo-marginàta,* Hook., B.M. 3657), has the lvs. edged white. Var. **tardiflòra** (*Fúnkia tardiflòra,* Hort.), blooms in late autumn: lvs. firmer and shorter petioled. Gn. 64, p. 297. Var. **undulàta** (*Fúnkia undulàta,* Otto & Dietr. *F. lancifòlia* var. *undulàta,* Bailey) is a form with undulate white-margined lvs. There is a form with 1-striped lvs., var. **univittàta,** Hort. Graceful. Fls. smaller than those of *H. cærulea.* **H. lóngipes** (*Fúnkia lóngipes,* Franch. & Sav.) is closely allied, but has broader lf.-blades decurrent on the petiole.

1910. Hosta cærulea.

H. Aòki, with "large glaucous-green lvs." is advertised. It has been offered in this country from European sources, and is said to be apparently identical with Hosta Sieboldiana, except in time of blooming.—*H. aùrea,* Hort., variegated forms of various species.—*H. elàta,* Hort., "bears tall scapes of pale blue fls."—*H. gigantèa,* Hort., has "long spikes of blue fls."—*H. variegàta,* Hort.=variegated forms of various species, usually of H. cærulea or H. lancifolia.—*H. víridis-marginàta,* Hort., is probably a form of H. cærulea.

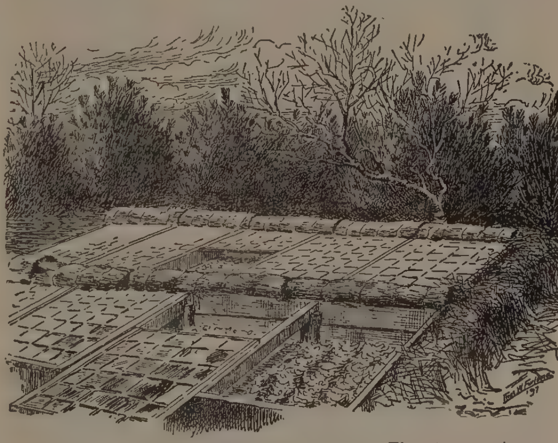
L. H. B.

HOTBEDS. Low glass structures in which plants are started or grown, usually heated by fermenting vegetable substances, such as stable-manure, although fire heat is occasionally applied, steam, hot water and flues being used. Their usual place is some spot sloping to the south, where they are protected by buildings, evergreen screens or board fences, from the north and west winds (Fig. 1911). The frames are made either of plank or boards and may be portable, or built in place, the former being taken down and packed away except when needed. A tight board fence 6 feet high, as a windbreak, is desirable, as it will also serve as a support for the shutters, mats and sash when they are removed from the bed, and it will answer best for this purpose if it inclines a foot or so to the north.

When movable frames (Fig. 1912) are used, they are generally constructed of 2-inch plank, the side pieces being from 9 to 12 feet and the ends 6 feet in length, to receive either three or four ordinary sash, which are 3 by 6 feet. The north side of the frame is made 15 inches wide, while the south side is but 9 or 10 inches, thus giving a slope to the south, which will permit the water to run off and favor the passage of the sun's rays through the glass. The end pieces are 6 feet in length, and in width taper from 15 inches at one end to 9 or 10 at the other, so as to fit the side boards. The plank for portable hotbed frames may be held in place by means of stakes, or iron rods or bolts may be fastened to the ends of the side pieces so that they can pass through the holes in the ends of the frame, which can then be secured by keys or nuts. As supports for the sash and to hold the sides of the frame in place, cross-strips of board 3 inches wide are sunk into the upper edge every 3 feet, and another strip with a width equal to the thickness of the sash is fastened on edge to the center of its side. Frames of this size require a slightly deeper mass of heating material than would be necessary for larger frames, and when they are to be used during the winter, it is well to excavate to the depth of 2½ feet and for a space 2 feet longer and wider than the frame, and after the hole has been filled with heating material, the material should be well tramped down. The frame is then put in place and manure is banked about it.

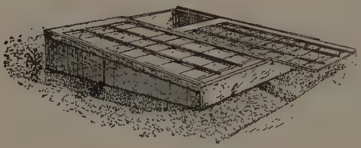
For permanent frames, rough 1-inch boards may be used, although 2-inch plank will be found far more durable. Stout stakes should be driven into the ground about 4 feet apart, where the north line of the bed is to be located. These should project above the surface from 12 to 15 inches, and should be boarded up from a point just below the level of the ground, so that the stakes will be on the north side of the frame. A second row of stakes should then be driven at a distance from the first row equal to the length of the sash, which is usually 6 feet, although other lengths are sometimes used. The south wall of the frame should then be boarded up so that it will be 5 or 6 inches lower than the north wall, after which the end should be closed and cross-pieces should be fitted, the same as for the portable sash. To prevent frost from working into the frame, soil should be taken from the inside and banked against the boards outside, so that it will reach two-thirds of the way to the top of the frame, and when the bed is ready for use, 3 or 4 inches of horse-manure should be spread over this. The frame should be placed about 3 feet from the fence, and if other rows are needed, there should be alleys about 7 feet wide between them.

Instead of boards or planks, concrete may be used for the walls of permanent frames. Forms should be set so that the lower part of the wall will be 4 inches thick but it may be only 2½ or 3 inches on the top. The excavation for the wall should extend about 1 foot below the surface and to prevent the settling of the concrete walls, when the excavation for the bed itself



1911. Hotbed sheltered by a hedge. The straw mats have been rolled off.

is made, concrete piers about 6 inches square should be built every 6 feet for the wall to rest upon. They should extend nearly 2 feet below the wall. The walls of the excavation will serve as a form for the piers and if care is taken in making the excavation for the wall itself, there will be no need of making a form for the outside of the walls below the surface, but plank should be set up for the inside of the walls, and for both sides of the wall above the surface. For making the grout, use four parts of gravel, two parts of sharp sand and one part of cement. Mix the sand and gravel and then after adding and thoroughly mixing the cement, pour on water enough to make a "wet mix." Pour the grout into the form, thoroughly packing it, and then allow the form to remain until it has set.



1912. Hotbed with movable frame.

Hotbed sash.

The size that has been found most satisfactory for hotbed sash is 3 by 6 feet, as when larger than this they are not readily handled by one man. While pine and other native lumber may be used, cypress is generally perferred, as it is much more durable and costs but little if any more than clear pine. The sides and upper ends of the sash are made from 3 by 1½-inch strips, grooved to receive the glass, while the lower end is about 1 by 5 inches. The center strips are 1 by 1½ inches. For glazing hotbed sash, single-strength 10 by 12 glass is commonly used, as three rows of this size will fill a sash 3 feet wide. While double-strength glass will be less easily broken, the increased weight is an objection to its use. The use of double-glazed sash is often advised, but aside from the extra cost, it will be found that the sash will be heavy to handle and, if used near where soft coal is burned, the bottom rows of glass will soon become nearly opaque and it will be necessary to reglaze the sash in order to wash the glass. Where there will be no trouble from soot and the sash is to be used for the covering of half-hardy plants in the winter, double-glazed sash may be used with satisfaction. The sash should receive two coats of paint, and after the glass, which may be either lapped or butted, has been set, it should be given a third coat.

Mats and shutters.

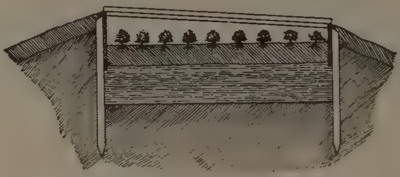
For covering the frames on cold nights during the winter and early spring months, straw mats are often used, although those made of burlap are generally preferred. The burlap may be either single or doubled, or it may be stuffed with straw, excelsior or other materials. Quilted mats filled with combination wool are very warm and quite durable. During the winter, wooden shutters are also desirable to place over the mats, as they assist in holding the heat, and by keeping the mats dry, aid in preserving them.

Heating material for hotbeds.

To provide heat for the beds decomposing horse-manure is generally used. While a large amount of straw is not desirable, the presence of urine-soaked bedding with the manure to the extent of one-third its bulk is not objectionable, as it will lengthen the heating period of the manure. Unless straw is mixed with the manure, it will be well to add forest leaves to the amount of one-third to one-half the amount of the manure. The heating material should be forked over and placed in a pile 5 to 6 feet wide, 3 to 4 feet high and of any desired length. If the manure and straw are dry, it will be well to moisten them with a fine spray. In case there is but a small amount of manure, it will be best to use warm water, though in all cases the soaking of the manure should be avoided. Within four or five days the giving off of steam will indicate that heating has commenced. The pile should then be forked over, working the outer portions into the center.

The amount of heating material that will be required for a hotbed will vary with the crop, as well as with the location and season. For zero weather, there should be at least 18 inches of heating material after it has been well packed down, and 24 inches will be desirable in midwinter in the northern states, while 6 to 8 inches may answer where only a few degrees of frost are expected. For 18 inches of manure, the excavation should be made to a depth of 28 inches below the level of the south side of the frame, and 31 inches below that of the north side. After the manure has warmed through for the second time it should be placed in the excavation, spreading it evenly and packing it down with the fork, but leaving it for a few days before tramping it. Care should be taken to have the corners well filled, that an even settling may be secured. After the manure has again warmed up, it should be thoroughly tramped.

The bed is then ready for the soil, which should be quite rich and contain a large amount of sand and humus, a compost of decomposed pasture sods with one-third their bulk of rotten manure being excellent for the purpose. The thickness of the soil should vary from 5 to 7 inches, the greater depth being desirable for radishes and other root crops (Fig. 1913). When boxes of plants are to be placed in the beds, the depth of soil need not be more than 3 inches. For a few days the bed will be quite warm, but when the temperature of the soil has dropped below 90° the seeds may be sown or the plants set out.

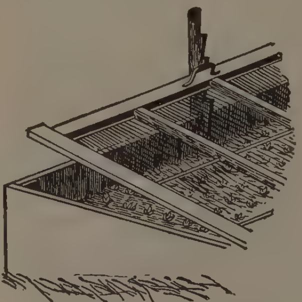


1913. Hotbed in cross-section.

In severe weather the mats and shutters should be placed on the bed at night and should be removed in the morning. When the sun is shining, or if the bed is very hot, it should be ventilated by raising (Fig. 1914) or slipping down (Fig. 1912) the sash, the amount depending upon the season and the condition of the bed. By the middle of the afternoon the sash should be closed and the covering should be replaced before night. When used in the winter time, the hotbed should be either sunk in the ground or well banked up with soil or manure, so as to keep out the frost.

Fire-heated hotbeds.

Especially if the beds are to be used during the winter months, and where there is an abundance of wood for fuel, it is advisable to use artificial heat for hotbeds. The simplest and cheapest method of heating is by means of hot-air flues. These do not differ materially from greenhouse flues except that they run underground and 6-inch sewer-pipe is used for them. The best results are obtained when the beds are built on the slope of a hillside, as this improves the draft. A



1914. Ventilating the hotbed.

small furnace or firebox is constructed of brick or concrete at the lower end of the frames from which one or more lines of hotbeds may be heated. As a rule, it is not best to heat more than two rows of frames from a furnace.

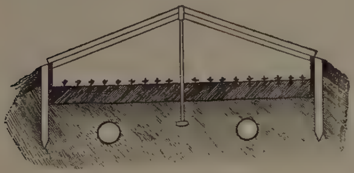
The flues are placed so that they will be 10 or 12 inches below the surface of the soil in the frames and they should rise gradually toward the farther end, where they should be connected with a pipe which will serve as a chimney. The height should vary from 6 to 10 feet, according to the length of the frames. For use in the winter, there should be two flues in a frame 12 feet wide.

When the hotbeds are located near a greenhouse heated by steam or hot water, it will be found satisfactory, particularly if the beds are higher than the heating plant, to put in either hot-water or steam pipes for heating them. While beds 6 feet in width may be heated in this way, it is better to make them about 12 feet wide, with a ridge in the center and a row of hotbed sash on each side. To heat such a frame with hot water, a 2½-inch flow-pipe should be run just under the ridge and there should be one or two 2-inch returns on each of the side walls. For use in the spring, one return on a side would answer, but in the winter months two will be necessary in sections where the mercury reaches zero, unless the beds are covered to prevent the escape of the heat. When steam is used, the feed-pipe should be 1½- or 2-inch and 1¼-inch pipe should be used for the returns.

In the northern states, it is seldom desirable to use hotbeds of any kind for the growing of winter crops, as not only can better results be secured in greenhouses, for which the cost will be but little more, but the work of handling the hotbeds in cold, stormy weather will be very disagreeable and unsatisfactory. In the South, however, hotbeds answer very well for winter use, both for growing plants for the truck-garden and for the forcing of various vegetable crops, although even there the simply constructed greenhouses would be more satisfactory.

Coldframes.

As an adjunct to the greenhouse when one is growing truck-crops, or bedding-plants, a coldframe will be found very helpful. These differ from hotbeds only in relying upon the sun for their heat. The surface of the soil should be from 6 to 12 inches below the glass. If plants are to be grown in the soil of a frame, care should be taken that it is adapted to the crop and that it is well stored with available plant-food. In many cases the frames are merely used for the hardening of plants which have been grown in the greenhouse, or for the carrying of half-hardy plants through the winter. For these purposes the soil in the frames should be of a sandy or porous nature.

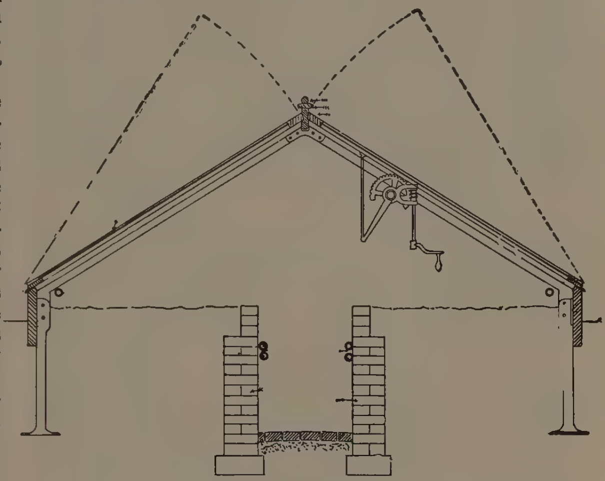


1915. Fire hotbed.

Glass sash should be used for covering the frames in the winter but, in the spring, canvas and other substitutes answer very well, particularly when the frames are to be used for the growing of seedlings. A long strip of canvas may be stretched lengthwise of the bed as a covering at night and upon cold days, and removed in whole or in part in pleasant weather. Oiled paper and water-proofed muslin are also used as substitutes for glass in hotbed sash.

Management of hotbeds.

If the weather is mild during the latter part of February, the manure can be procured and prepared for use so that the hotbed may be started about the first of March. If properly constructed they will provide heat for two months, and can then be used during May as coldframes, thus making it possible to take off two crops in the spring. Although it is not often practised, they may be used in the fall for growing a crop of lettuce or other vegetables, which can be matured before the first of December.



1916. Hotbed or forcing-house heated by hot water.

If a greenhouse is not available for starting the plants, seeds of lettuce, radishes, cabbages and other of the hardier plants may be sown in the hotbed in the spring as soon as it is ready, in rows 4 or 5 inches apart. When the first true leaf appears, the radishes should be thinned and the other plants transplanted to about 2 inches. Later on, the lettuce plants should be placed about 8 inches apart each way. If the weather is so cold that the bed should not be kept open, the seeds may be sown and the first transplanting may be in flats or boxes, which can then be placed in the beds. Aside from proper ventilation, covering and watering, the beds should occasionally be weeded and the soil stirred. About the first of April, tomatoes, cucumbers and similar plants may be started. As soon as one crop is taken off another should be placed in the beds, and by deepening the soil they may be used during the early summer for growing cauliflower, tomatoes and cucumbers.

L. R. Taft.

HOTÈIA: *Astilbe.*

HOTTÒNIA (Peter Hotton, 1648–1709, professor at Leyden). *Primulàceæ.* Featherfoil. Two species of water plants, perennial, not very ornamental, but suitable for small aquaria.

Plants rooting or floating, the sts. spongy and air-bearing, the peduncles hollow and erect: lvs. submersed and dissected, passing into entire narrow whorled bracts: fls. white or purplish, whorled and racemose, emersed; corolla salverform, with 5-parted limb; ovary free: fr. a globular more or less 5-valved many-seeded caps.—The European species is procurable from dealers in aquatics; the American can be gathered in shallow, stagnant ponds from Mass. to W. N. Y. and south to Fla. and La.

palústris, Linn., the European plant, is an herb with creeping rootstock, whorled leafy branches entirely submerged and alternate, pinnately dissected lvs., the divisions numerous and linear. From the center of the whorl of branches a single leafless fl.-st. rises out of the water in summer, bearing a raceme with several whorls of 3–5 or 6 handsome pale purple fls., apparently with

5 petals, but actually with a short corolla-tube below the lobes; stamens 5, inserted on the tube of the corolla: caps. subglobose, with 5 lateral valves; seeds numerous.—The plants root in the mud or float, and the fls. are about ¾in. diam.

inflâta, Ell., the American plant, has spongy sts. and clustered peduncles, which are partly above water, inflated, jointed, the lowest joint 2–4 in. long and sometimes 1 in. thick, the others 1–3 in number and successively shorter: fls. white in whorls of 2–10 at the joints. B.B. 2:586.—Neither species is advertised. Like all aquarium plants, they are interesting, but they have no horticultural value otherwise. Both plants are called featherfoil and water-violet; the American also water-feather and water-yarrow. The European species has dimorphic fls., after the manner of Primula. The earlier fls. in the American species are cleistogamous. L. H. B.

HOULLÈTIA (after Houllet, French gardener). *Orchidàceæ.* Epiphytic, pseudobulbous orchids, allied to Stanhopea, and blooming in summer.

Pseudobulbs conical, 1-lvd.: lvs. lanceolate, plicate: sepals and petals usually nearly equal; labellum continuous with the clavate, arcuate column; pollinia 2, on a long caudicle.—About 8 species from S. Amer.

odoratíssima, Lind. Sepals and petals reddish brown; labellum white, with 2 crimson appendages midway of its length. Colombia. G.C. II. 24:777. C.O. 1. Var. **antioquénsis,** André (*H. antioquénsis,* Hort.), has labellum white, tinged yellow. I.H. 17:12.

Brocklehurstiàna, Lindl. Fls. 5–8, about 3 in. across, brownish red, dotted with brown-purple; sepals oblong, obtuse, the lateral ones slightly united at base; petals narrower, obovate; labellum yellow, thickly dotted with brown-purple; from its lower half 2 linear appendages have their origin. Brazil. B.M. 4072. P.M. 9:49. R.H. 1885:492.

pícta, Lind. & Reichb. f. Fls. 6–10; sepals oblong, brownish, unspotted above, tessellated with yellow below; petals similarly colored; labellum yellow, spotted or dotted with brown-purple or red-purple, the end hastate; apex recurved, pale yellow veined with crimson. Colombia. B.M. 6305.

Wállisii, Lind. & Reichb. f. (*H. chrysántha,* Lind. & André). Fls. about 2 in. across; sepals and petals yellow, blotched inside with brown-purple; labellum yellow, dotted with crimson. Colombia. G.C. II. 18:437; III. 50:177. G.M. 54:661. J.H. III. 63:315. I.H. 18:71.

H. Sánderi, Rolfe. Raceme 2–3-fld.; fls. large, pale yellow; sepals about 1¼ in. long, the dorsal elliptic, the lateral broadly ovate; petals broader, nearly orbicular, about as long as sepals. Peru. B.M. 8346.

Oakes Ames.
George V. Nash.†

HOUSE PLANTS (Figs. 1917–1919) are those plants that can be grown in the ordinary rooms of dwelling-houses. They may be hardy or tender; only such as are suitable for this purpose will be considered here.

In the living-rooms of the modern well-built house, plants must contend against difficulties which did not exist in the less carefully equipped dwellings of fifty years ago or earlier. The present methods of heating and lighting, by gas or kerosene lamps, not electricity, produce a dry atmosphere which is inimical to vegetable growth. In houses lighted by electricity, and heated by any system which introduces fresh air in abundance, the hindrance is not so troublesome. Too much heat and dry air are harder for plants to endure than insufficient light, but it is also lack of light which makes it difficult to grow flowering plants in houses. Dust and insects do harm, but can be checked.

For the above reasons it is important to choose house plants which are adapted to resist a dry atmosphere, a high temperature and inadequate light. Such examples can be found among certain tropical plants with coriaceous leaves and small stomata, what the florists call foliage plants, e. g., rubber trees, palms, and the like. These make the best foundation upon which any successful system of growing plants in houses can be built. Flowering plants can also be used, but they should be introduced from time to time, each in its proper season, when about to bloom or in bloom, and not considered a part of the permanent arrangement. After flowering they should be removed: their function is not unlike the use of cut-flowers, but they last longer and are not more expensive, while they largely increase the attraction of the window-garden.

1917. Pot-plants in the window.

The best rooms for plants are those which get the most sun, and the best positions are those nearest the windows, where there is not only more light but more fresh air. A large palm, fern or rubber will grow in an entry or poorly lighted corner, but the best place is that which is best lighted. Plants do well in a kitchen, the moisture from the cooking helping them materially; it is by no means a bad hospital for unhealthy specimens.

A conservatory is desirable but not always obtainable on account of the expense; it should agree with the architecture of the house and have the proper aspect. The construction should be durable, the walls and roof low and, a point often neglected, great attention should be paid to ventilation. This should be given not only in the roof, the very apex when possible, but also on the sides at the bottom. The trouble comes in early autumn when the plants are first potted up and again when the sun begins to be hotter in February, March and April. Fresh air should be given all winter on bright days, but it is particularly needed at the times named above. Shade is also advisable on warm sunny days and a system of screens either inside or out can be devised. The florists' method of painting the glass is good but unsightly. When a regular conservatory is unobtainable, a plantroom can sometimes be made which is most satisfactory and at comparatively small cost. It is often possible to utilize a part of the basement for such purpose. A southeast or south exposure is best, but if it faces southwest or even west no trouble follows. Such a room should be well furnished with windows which open both at top and bottom. The floor should be of concrete or porous tile and the walls covered with material which is unharmed by water;

good drainage should be provided. Such a room is not only capable of keeping plants in good condition but can also be used for starting seedlings and cuttings. The temperature can be kept well above freezing and under 50° F. sometimes without extra fire heat when such a room opens into a heated cellar. It can be used not only for growing plants but also as a storeroom from which plants can be taken for decorating the living-rooms; there is no better place for all bulbous plants from the time they are taken out of the frame until they show flower-buds well developed.

In rooms in which plants are kept, any device by which the atmospheric moisture can be increased is desirable: oilcloth on the floor, or a floor of porous tiles; a zinc tray, in which the pots can be set and surrounded with moss; saucers under the pots, the pots being raised slightly to prevent the roots of the plants standing in the water which runs through. By these aids not only can plenty of water be given to the roots, but there will also be some opportunity to sprinkle the leaves, while the evaporation of surplus water will dampen the air. The Japanese porcelain pots are not only ornamental but useful; the glaze prevents undue evaporation from the sides, and the legs hold the pot well above the water which may collect in the saucer: they are in every way excellent. Wooden tubs are serviceable for large plants or for any which are likely to be exposed to frost, either before or after bringing into the house. Plants should never be overpotted, but the larger the bulk of earth the easier it can be kept uniformly moist; from the wider surface, too, there is more evaporation. For these reasons it is sometimes a good plan to have window-boxes in which several plants can be grown; or the boxes can be filled with moss in which the pots can be plunged. All pots, tubs or boxes for growing plants should have holes in the bottom through which water can pass freely.

Much trouble is likely to come from the use of unsuitable potting soil. Procure it from an experienced florist, or make it yourself of equal parts rotted sods, old leaf-mold, well-decayed cow-manure and clean, sharp sand: discard tea leaves, chip dirt, and the decomposed remains of dead stumps. The soil should always be moist when used, not too wet and never dry: it should be made firm, not hard, and a good space left between the surface and rim. Large pots should be drained with potsherds and moss. The best time for potting is just before the plant begins to grow; the next best is just before growth ceases, thus giving the plant opportunity to establish itself in its new quarters before it stops growing. It is not always easy to do this properly at home, and large and valuable plants should be sent to a florist. Plants growing in the open air should be lifted and potted two weeks or more before bringing into the house, not only before frost but before the nights are cool. Keep them at first in a shady place, gradually accustom them to the sunlight, and carefully avoid all drafts. Do not give too much water at the root: some wilting is unavoidable, and cannot be prevented by heavy watering. Give one good application when they are first potted, and sprinkle the foliage and surroundings in the middle of the day. After they are established, keep them out-of-doors, on the piazza or porch, until there is danger of frost, but try to bring them into the house before the furnace fires are lighted.

A period of rest is natural to all plants. Amateurs often make mistakes in trying to force plants to grow all winter in the house after a vigorous growth in the open ground all summer. Such plants should be rested, kept cool at first and water withheld, but never to such an extent as to shrivel the wood. No rules can be given for watering, the most important detail of plant-growing. Water must be given as it is required, a knowledge to be gained from experience only. This may be once a day or once a week, twice a day or once in two days. The smaller the pot and the more vigorous the growth, the oftener it will be required. In hot weather and in dry rooms more water is needed than in cool rooms and on damp, cloudy days. It should always be given in sufficient quantity to pass through the hole in the bottom of the pot: here it can remain an hour or more, and part of it will soak up, back into the pot, but the surplus should be taken away with a sponge, unless the pot has legs or it is a plant like calla, English ivy, or some ferns, which are uninjured by an over-supply. Water given to the foliage of house plants in the form of spray is always helpful.

Insects, dust and sometimes fungous pests are troublesome to house plants, due largely to insufficient watering and lack of ventilation. The best remedy is frequent washings with warm water and a sponge for plants with large leaves. All plants can be easily cleaned at the kitchen sink or in the bathtub, or advantage can be taken of a mild day, and the work done in the yard with the hose. The forcible application of water will remove most insects, but if scale appears it must be taken off with a stiff brush. Whale-oil and tobacco soap are too rank for house use; fir-tree oil and Gishurst's compound are less obnoxious. They can be used when the plants are washed with sponge or brush. The florists' preventive against greenfly is impracticable: enough tobacco smoke to harm them would not be tolerated in living-rooms. Tobacco stems may be burned, however, in the plantroom described above if a well-fitted door is provided and precautions are taken to make the ceiling air-tight. It is altogether too dangerous to use cyanide of potassium in any form of plant-growing in the house. The red-spider can be driven off by spraying with an atomizer, if discovered in time. Some plants are not attacked by insects, but are injured by dust, e.g., the rubber-tree. Dusting when dry is better than nothing, but washing is best. If fungous diseases appear, the plants should be isolated, giving a chance to recover, or be thrown away.

Ventilation is an important factor in keeping house plants in good condition. Open the windows on bright days: the fresh air is moist and therefore grateful, and will do no harm, even if the plants are near the glass, so long as the sun shines and discretion is exercised.

1918. A window-garden.

The night temperature need never exceed 50° F., and a drop of 5° or even 10° is not likely to do any harm. Precautions must be taken to exclude frost; the blinds must be shut and the curtains pulled down on cold nights. A layer of newspapers between the plants and the windows is a protection in extremely bad weather, or a large kerosene lamp can be allowed to burn all night near the plants.

A list of suitable foliage plants for the house: *Ficus elastica*, the rubber plant; *F. religiosa* (peepul tree) and most of the other strong-growing evergreen species. *Livistona sinensis*, *Corypha australis*, *Chamærops Fortunei* and *Rhapis japonica*, all good fan-palms (the first is the best); *Phœnix reclinata*, *P. rupicola* and *P. canariensis* are the best date-palms. *Seaforthia elegans*, *Howea Belmoreana*, *Kentia Forsteriana*, *Areca Baueri*, *A. rubra* and *Cocos Weddeliana* are all good palms, but require more care and heat than the fan- and date-palms. *Cycas revoluta* (sago-palm), *Curculigo recurvata*, *Aspidistra lurida*, *Pandanus utilis* (screw pine), *P. Veitchii*, *Phormium tenax* (New Zealand flax), *Cyperus alternifolius*, *Papyrus antiquorum*, Cordyline, Dracæna, *Agave americana* (century plant), Pittosporum, *Grevillea robusta*, English ivy, wandering jew and some species of cactus all do well in ordinary rooms. *Daphne odora*, laurestinus, *Olea fragrans* and orange trees are both flowering and foliage plants, but require a cooler room than any of the preceding varieties.

Good flowering plants are *Azalea indica* and *Camellia japonica*, both of which should be kept in a cool room when not in bloom. Calla and begonia both do well. Chrysanthemums, cinerarias, gloxinias, gladioli, cyclamens, Chinese and English primroses, freesia, oxalis, fuchsia, mahernia, euphorbia, heliotrope, pelargonium and lily-of-the-valley can be brought into the rooms when in flower, and last a reasonable time in good condition. Hyacinths, tulips, narcissi and crocus, if potted in October, kept covered up out-of-doors until cold weather, stored in a cool cellar until the middle of January and then brought into warm rooms, will give flowers: a succession can be maintained by bringing them into warmth at intervals. (See *Bulb.*)

1919. An attractive corner of pandanus, begonia, and wandering jew.

The following varieties of hyacinths and tulips are particularly recommended for growing in living-rooms under ordinary circumstances:

Hyacinths.—The single sorts are much better than the double and more easily handled. Single reds and pinks: Gen. Pelissier, Gigantea, King of the Belgians, La Victoire, Norma. Single white: La Grandesse, L'Innocence, Madame Van der Hoop, Mr. Plimsoll. Single blue: Czar Peter, Enchantress, Grand Lilas, King of the Blues, Lord Derby, Queen of the Blues. Double red: Grootvorst, Lord Wellington, Noble par Merite. Double white: Isabella, La Grandesse. Double blue: Bloksberg, Garrick, Van Speyk. Double yellow: Goethe.

Tulips, early single.—Albion (White Hawk), white. Belle Alliance (Waterloo), red. Couleur Cardinal, bronze-red. Cramoisi Brillant, bright scarlet. Goldfinch, yellow. Keizerkroon, red and yellow. La Reine, white turning pink. Mon Tresor, yellow. Pottebakker, scarlet. Primrose Queen, sulfur-yellow. Prince of Austria, orange-red. Proserpine, carmine. Rose Grisde Lin, pink. Rose Luisante, deep pink. Thomas Moore, orange. Vermilion Brilliant, scarlet. Yellow Prince, yellow.

Tulips, double.—Couronne d'Or, yellow flushed red. Imperator rubrorum, red. Murillo, best light pink. Salvator Rosa, deep pink. Tournesol, yellow.

All the Duc Van Thol tulips are excellent for early forcing, particularly the scarlet. The Darwin tulips are now sometimes forced, but they are not suitable for growing in houses. The Parrot Cottage tulips and the like are not grown in this way.

Roman hyacinths are easily forced and with the Paper White narcissus can be flowered between Thanksgiving and Christmas. Narcissus Campernelle var. rugulosus, the Chinese sacred narcissus, the double Roman, and most varieties of Polyanthus narcissus flower earlier than the other sorts.

B. M. Watson.

HOUSTÒNIA (Dr. Wm. Houston, who collected in the West Indies and Mexico, died 1733 in Jamaica). *Rubiàceæ.* About twenty-five North American small herbs or rarely sub-shrubs, with pretty white, blue or purple flowers, some of the species cultivated in wild gardens and rockeries.

Plants usually tufted or growing in colonies: lvs. small, opposite, on the slender sts: parts of the fls. in 4's, the corolla gamopetalous and funnelform or salverform; stamens and styles polymorphous; stigmas 2: caps. opening near the top, partly superior.—The species are native on the Atlantic side of the continent and in Mex. Some of the small herbaceous species are sometimes transferred to cult. grounds, although the kinds are little known as horticultural subjects. A moist, partly shaded place is to be recommended for most houstonias, because their flowering season is thereby prolonged and the plants retain their foliage much longer than in a drier and sunny position. Collected plants are not difficult to establish. Prop. by division. The following perennial species have been offered by American dealers:

A. *Plant tall (4–18 in.): peduncles many-fld.*

purpùrea, Linn. Tufted, 3–18 in. high, bearing offsets, glabrous or pubescent: radical lvs. round-ovate or oblong to lanceolate, short-stalked: fls. in late spring or summer, the corolla funnelform, purple; calyx-lobes exceeding the half-free caps. Md. and Iowa to Texas.

AA. *Plant lower (1–6 in.): peduncles 1-fld.*

cærùlea, Linn. BLUETS. INNOCENCE. QUAKER LADY. Fig. 1920. Little tufted perennials, 3–6 in. high, the sts. glabrous: radical lvs. spatulate to obovate, hairy, short-petioled, the st.-lvs. small: corolla salverform, the tube much exceeding the calyx-lobes, varying from blue to white, with a yellow eye. B.M. 370. Gn.W. 20:868.—Charming little plant in grassy places in the northeastern states and southward in the Alleghany region; early spring. Excellent for rockwork and grassy borders. In gardens, may be treated as annual or biennial.

serpyllifòlia, Michx. Prostrate and extensively creeping: radical lvs. orbicular to ovate-spatulate and abruptly petioled: corolla rather larger than that of *H. cærulea,* deep violet-blue (often white). Pa., southward. G.W. 12, p. 151.—Early spring. L. H. B.†

HOÙTTEA: *Vanhouttea.*

HOUTTUÝNIA (M. Houttuyn, of Amsterdam, writer on natural history in 1774–1783). *Saururàceæ.* One oriental species, the Californian species being now referred to Anemopsis (p. 287, Vol. I). *H. cordàta,* Thunb., is a perennial herb, growing ½–3 ft. high, from a creeping rootstock, from Himalaya to China and Japan: st. leafy, nearly simple, angular: lvs. alternate, simple, broadly ovate-cordate, 5-nerved: fls. very small, naked, in a short spike; stamens 3; short spike subtended by a corolla-like spathe in 4 ovate spreading white parts. B.M. 2731. G.W. 11, p. 385.—Grows in ditches along waysides, up to 5,000 ft. in India. Perhaps to be recommended for moist places in mild climates. L. H. B.

HÒVEA (probably A. P. Hove, Polish botanist). Syn. *Poirètia. Leguminòsæ.* Ornamental, unarmed or seldom thorny, greenhouse shrubs: lvs. alternate, simple, entire or prickly-toothed, glabrous above, often tomentose beneath; stipules setaceous, minute or none: fls. blue or purple, in axillary clusters or very short racemes or rarely solitary; upper lobes of calyx united into a broad, truncate upper lip, the 3 lower ones much smaller, lanceolate; petals clawed; standard nearly orbicular, emarginate: pod sessile or stipitate, the valves at length entirely spreading.—Eleven species, confined to Austral. Best prop. by seeds sown in spring in well-drained pots of sandy peat and placed over a gentle bottom heat. When 2–3 in. high, the points should be pinched out to induce a bushy habit. After they are established, grow in a cool greenhouse with plenty of air. **H. Célsii,** Bonpl. (*H. ellíptica,* DC.). A tall shrub, sometimes 8–10 ft. high: lvs. ovate-elliptical to narrow-lanceolate: fls. blue, in clusters or short racemes, the pedicels often as long as or longer than the calyx. B.R. 280. B.M. 2005. L.B.C. 15:1488. Gn. 59, p. 178, desc.; 75, p. 225. L. H. B.

HOVÈNIA (after David Hoven, Senator of Amsterdam). *Rhamnàceæ.* Ornamental shrub or small tree, grown chiefly for its handsome foliage.

Leaves deciduous, alternate, without stipules, long-petioled: fls. in axillary and terminal racemes; calyx-lobes, petals and stamens 5, style 3-parted: fr. 3-celled and 3-seeded, indehiscent.—One species in Japan, China and Himalayas.

Hovenia has greenish inconspicuous flowers in axillary peduncled cymes, and small globular fruits on reddish, fleshy and edible peduncles. It grows into a small round-headed tree, with handsome somewhat shining foliage. It thrives best in sandy loam and has proved fairly hardy in favorable positions at the Arnold Arboretum. Propagation is by seeds, also by root-cuttings and cuttings of ripened wood under glass.

dúlcis, Thunb. (*H. acérba,* Lindl. *H. inæquàlis,* DC.). JAPANESE RAISIN TREE. To 30 ft.: lvs. cordate-ovate or ovate-acuminate, serrate, sometimes nearly entire, almost glabrous or pubescent on the veins beneath, 4–6 in. long: cymes many-fld. Japan, China, Himalayas. S.Z. 73, 74. B.M. 2360. B.R. 501. S.I.F. 2:47. A.G. 12:80.

ALFRED REHDER.

1920. Houstonia cærulea.

HÓWEA (named for Lord Howe's Island, where these 2 species grow). Also written *Howeia. Palmàceæ,* tribe *Arèceæ.* Erect spineless palms known to the trade as kentias, and certainly ranking among the six most popular palms for house culture.

Caudex stout, ringed: lvs. terminal, numerous, dense, equally pinnatisect; segms. narrow, acuminate: spadices 2–3 ft. long, solitary or 3–5 from 1 spathe, thick, cylindrical, nodding or pendulous; peduncle long, compressed at the base; spathe solitary, as long as the spadix, cylindrical, 2-keeled toward the apex, longitudinally split: bracts bordering the channels; bractlets scaly: fls. sunk in the deep furrows of the spadix, the staminate nearly an inch long: fr. 1½ in. long, olive-shaped.

They have the habit of Kentia, but their flowers differ widely. Howea belongs to a subtribe in which the flowers in each spadix are attached to the stem between the bases of opposite leaves, while Kentia belongs to another subtribe in which the flowers are attached at a lower point. Also Howea has symmetrical staminate flowers with rotund sepals, while in Kentia the staminate flowers are not symmetrical, the sepals being small and acute. Howea's nearest cultivated ally is Linospadix, from which it is distinguished by the following characters: staminate flowers with very numerous stamens, the anthers erect and fastened at the base; pistillate flowers with no staminodes; ovule erect. *H. Belmoreana* is the more popular and as a house plant may be readily told from *H. Forsteriana* by the more ascending position of its leaf-segments, as in Fig. 1921; the leaves of *H. Forsteriana* are more flat or the sides pendent.

The two species of this genus are beyond a doubt the most popular and also the most satisfactory palms in the trade for decorative work in general, and in consequence of the great and growing demand are grown by tens of thousands in the large nurseries. There does not seem to be any record of either of these species having borne fruit in cultivation in this country, and the trade, therefore, depends on imported seeds, which are gathered in immense quantities on Lord Howe's Island, usually shipped from thence to Sydney, New South

Wales, and from the latter port to either London or New York. This long voyage is a severe test of the vitality of such seeds, and frequently results in faulty germination, the average of germination seldom exceeding 50 per cent, and is often much less. Two heavy shipments of Howea seeds are made each year, the first installment arriving in February or March, and the second in September or October. Many growers favor the autumn shipment of these seeds as giving the best results. The seeds should be sown at once on their arrival, the practice followed by large growers being that of broadcasting the seeds on a side-bench in a warm greenhouse on 2 to 3 inches of light soil, then covering them with 1 inch of the same compost, watering liberally and keeping up a bottom heat of about 80°. Under such treatment some of the seeds may germinate in two months, but others in the same lot may not start for eight or nine months, from which it will be seen that the operation extends over a considerable period of time. The seedlings should be potted into small pots when the first leaf is expanded, kept moist and given a night temperature of 65°, the greenhouse in which they are placed being moderately shaded. In three to four months the young plants should be ready for shifting into 3-inch pots if properly cared for; from this time forward they do not require a higher night temperature than 60°. The howeas are not very particular in regard to soil, a rich, light loam answering very well for them, but a very stiff soil may be improved by the addition of one-fourth part of peat, and in all cases a reasonable proportion of fertilizers may be used to advantage. Scale insects are the most troublesome the grower has to contend with, and should be removed as rapidly as possible, else the foliage will be permanently disfigured. Of the two species referred to, *H. Belmoreana* is perhaps the greater favorite, being more compact in growth and extremely graceful in foliage, a plant of this species of a given age usually carrying a greater number of leaves than one of *H. Forsteriana* of the same age, and the leaves having more leaflets than those of the latter species. The seeds of the two species are very similar in appearance, though those of *H. Belmoreana* frequently average a larger size, and while those of the last-named species require about three years to mature on the tree, the seeds of *H. Forsteriana* ripen in about twelve months. For house culture by amateurs, see *Palms*. (W. H. Taplin.)

1921. Howea Belmoreana, one of the most popular palms.

Belmoreàna, Becc. (*Kéntia Belmoreàna*, F. Muell. *Grisebáchia Belmoreàna*, H. Wendl. & Drude). Curly Palm. Fig. 1921. Described and distinguished above. B.M. 7018. R.H. 1897:256 and p. 257. G.C. III. 8:75. I.H. 21:191. A.G. 13:141; 16:345. Mn. 9:25. Gn.M. 6:288. Var. **variegàta,** Hort. Advertised 1895.

Forsteriàna, Becc. (*Kéntia Forsteriàna*, F. Muell. *Grisebáchia Forsteriàna*, H. Wendl. & Drude). Flat or Thatch-leaf Palm. G.C. III. 8:75, 533. S.H. 2:53. A.G. 16:346. A.F. 4:565; 14:701. G. 8:581. Gn. 73, p. 111. Gn. M. 6:289.

N. Taylor.†

HÓYA (Thomas Hoy was once gardener to the Duke of Northumberland). *Asclepiadàceæ*. Tropical climbing or trailing evergreen shrubs, bearing thick, opposite leaves and odd, often showy flowers in umbel-like clusters, grown under glass and one of them sometimes in window-gardens.

Corolla rotate, 5-lobed, thick and more or less waxy in appearance: crown rotate, of 5 thick and compressed fleshy appendages: pollen-masses short, fixed by their base in pairs to the 5 glands of the stigma: follicles acuminate, smooth: sts. twining, or climbing by means of roots.—Species perhaps 100, E. Asia to Austral.; difficult to determine in herbarium specimens.

Hoyas are summer-blooming plants, of comparatively easy culture. They need an intermediate or warm temperature. Let them rest or remain very slow in winter (50° in a dryish place), but start them into growth toward spring. In the summer they are sometimes plunged in the border, but better results are to be expected, as a rule, by keeping them in pots in the conservatory. In their growing and blooming season, give plenty of sun and air. They propagate by cuttings of the top-growth in spring, and also by layering. The latter method is particularly adaptable to *H. carnosa* and other species that climb by means of roots. The only species commonly known is *H. carnosa*.

A. *Plant distinctly climbing.*

carnòsa, R. Br. (*H. Motóskei*, Teijsm.). Wax-Plant. Twiner, and attaching itself to support by means of roots; ordinarily grown as a pot- or tub-plant, and reaching 5–8 ft. high, but growing twice and more this height when it has the opportunity: glabrous: lvs. succulent and shining, ovate-oblong, acute, short-stalked, entire: fls. white with pink center, fragrant, in axillary or inter-petiolar umbels, the crown-segms. very convex, and spreading into a horizontal star. S. China and Austral. B.M. 788 (as *Asclepias carnosa*). Gn. 69, p. 119. G. 25:123. A.G. 18:34.—The common species, and often seen in window-gardens. After the bloom is over (in summer) keep the plant in a cool place, that it may remain half-dormant. In late winter or spring, start it into growth. Do not cut off the spur which remains after the fls. pass, for this spur bears fls. again. The wax-plant is easy to manage, and it improves with age. Often trained as a permanent cover for a glasshouse wall. The chief drawback is the attacks of mealy-bug, but they may be kept off with a fine stream of water from the hose, and by handwork. In the South, it is nearly everblooming. There is a form (var. *variegàta*) with handsome variegated lvs. Lowe 44.

globulòsa, Hook. f. Hairy: lvs. elliptic-oblong or long-oblong, acuminate, rounded at the base, the midrib very stout, the petiole an inch or less long: fls. pale straw- or cream-color, the star-like crown-segms. white, with pink at the base, borne in dense, globular umbels: follicles a foot or more long. Sikkim. F.M. 1880:406.

G.C. II. 17:741.—A handsome species, requiring the general treatment given to *H. carnosa.*

austràlis, R. Br. Twiner, glabrous and succulent, apparently sometimes epiphytic: lvs. ovate, obovate to nearly orbicular, obtuse or short-acuminate, thick and fleshy: fls. white tinged pink, in simple umbels on peduncles that seldom surpass the petioles; corolla spreading, ½in. or less in diam., broadly 5-lobed; crown cup-shaped and expanding into horizontal concave prominently 2-keeled parts. Austral.

multiflòra, Blume (*H. coriàcea,* Lindl., not Blume. *Cyrtocèras multiflòrum,* Heynh. *C. floribúndum,* Maund. *Centrostémma multiflòrum,* Decne. *C. Lindleyànum,* Decne.). Stout and glabrous, climbing: lvs. linear-oblong, acute at both ends, the petiole short: fls. straw-yellow (corolla white tipped with buff), in many-fld. terminal and axillary umbels on peduncles 1–2 in. long; corolla-lobes ¾in. or less long; corolla-tube bearded at base; segms. of crown entire on inner angles. Malacca, etc. B.R. 25:18. B.M. 5173.

imperiàlis, Lindl. Lofty climber, with puberulent sts. and foliage: lvs. elliptic or linear-oblong, obtuse but with a short point: fls. immense (2–3 in. across), leathery, dull purple, somewhat pubescent near the white crown, the segms. triangular-acute: umbels drooping on long peduncles: follicles 9 in. long. E. Indies. B.M. 4397. F.S. 4:393, 394. R.H. 1900:576. J.H. III. 55:443. G. 7:607.—A noble hoya, requiring very rich soil and a rather high temperature. Although naturally a very tall climber, it can be made to flower in pots when 3 or 4 ft. high.

AA. *Plant trailing or nearly erect.*

bélla, Hook. (*H. Páxtoni,* Hort.). Slender, bushy, 1–2 ft. high, pubescent: lvs. an inch long, ovate-acute, very short-stalked, somewhat recurved: fls. ¾in. across, pure white, with very short and half-acute lobes, the crown-segms. boat-shaped and violet: umbels few-fld. and short-stalked. India. B.M. 4402. F.S. 4:399. J.H. III. 35:5. Gn.W. 4:793; 22. suppl. July 1.—Handsome little species; scarcely climbing.

H. campanulàta, Blume=Physostelma.—*H. fratérna,* Blume. Climbing, rooting near insertion of petioles: lvs. 6–12 in. long, very thick, elliptic, glossy above and pale beneath: fls. brownish red, in dense umbels; corolla rotate, pale buff with 5 red-brown blotches; lobes of crown round-ovate, concave with blood-red spot at base. Java. B.M. 4684. J.F. 4:385.—*H. fúsco-marginàta,* N. E. Br. Lvs. fleshy, ovate-lanceolate, 7–9 in. long, tawny on margins: fls. ochre-yellow to yellowish green, in many-fld. umbels on peduncles 2 in. or less long. Country unknown.—*H. ovalifòlia,* Wight & Arn. Slender, glabrous: lvs. more or less clustered, variable, being elliptic to ovate or lanceolate: fls. bright yellow with red corona, in large umbels. India. J.F. 1:64.—*H. pállida,* Lindl.=*H. parasítica,* Wall. (H. pallida, Lindl.). Tall climber: lvs. fleshy, variable, ovate-elliptic to lanceolate: fls. pale yellow or straw-color, the corona pinkish. India. B.R. 951. J.F. 1, p. 64.—*H. purpùreo-fúsca,* Hook. Twining, glabrous: lvs. ovate and acute: fls. purplish brown, in dense umbels; corolla rotate, pubescent above; crown-lobes ovate, nearly plane above. B.M. 4520. J.F. 1:30.

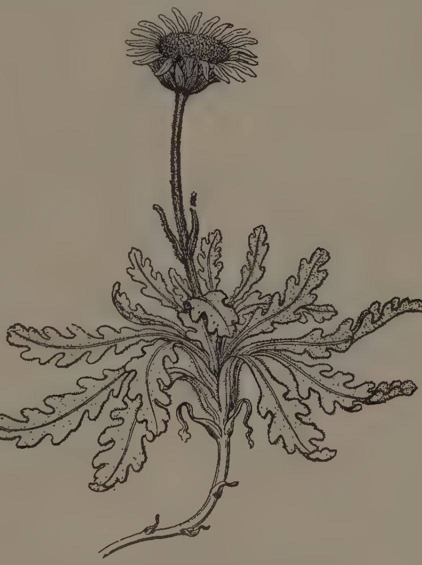
L. H. B.

HUCKLEBERRY: *Vaccinium* and *Blueberry;* also *Gaylussacia.*

HUDSÒNIA (for William Hudson, 1730–1793, an English botanist). *Cistàceæ.* Beach Heather. Three little heath-like shrubs of eastern North America, suitable for colonizing in dry places and along the seashore: low and diffusely branched, with narrow or scale-like or awl-like often closely pressed lvs.: fls. many and small, yellow, crowded on the upper parts of the branches; petals 5, obovate-oblong, exceeding the calyx; stamens many: fr. a 3-valved caps, included in the calyx. Allied to Helianthemum, but differing chiefly in the 2-ovuled cells of the ovary and in the scale-like or subulate imbricate lvs. *H. tomentòsa,* Nutt., on shores and dunes, and in pine-lands, New Bruns. to N. C. and far westward: lvs. oval to narrow-oblong, closely imbricated: fls. nearly or quite sessile: densely tufted, hoary, 4–8 in. high. May–July. *H. ericoìdes,* Linn., in sands and pine-lands near the coast, Newfoundland to N. C.: greenish, although downy: lvs. subulate and spreading: fls. on slender pedicels; at least 1 sepal with tooth near apex: 4 to 8 in. L.B.C. 2:192. *H. montàna,* Nutt., in mountains of N. C.: bushy and somewhat villous: lvs. narrow-subulate, somewhat spreading with age: fls. on slender pedicels; at least 1 sepal with linear-subulate lobe: tufted, the branches 4–6 in. long. They are hardy N. and handsome when covered with their bright yellow numerous fls., but very rarely cult., as they are difficult to grow and short-lived. The first species is a seashore plant and demands very sandy moderately moist soil; the second grows in dry sandy soil. Prop. by seeds and probably by cuttings.

Alfred Rehder.
L. H. B.

HUÉRNIA (Justus Huernius, or Heurnius, collector of Cape plants). Also spelled *Heurnia. Asclepiadàceæ.* Succulent dwarf perennials resembling Stapelia, but differing in having the angles between the corolla-lobes produced into teeth, the corolla campanulate, the corona toothed or lobed and adnate to base of corolla. They are greenhouse subjects, mostly from the Cape, but some from Trop. Afr. and one from Arabia. They appear not to be in the trade, but some of the 30 or more species may be found in collections of succulents.



1922. Hulsea nana. (×⅓)

HUERNIÓPSIS (*Huernia-like*). Also spelled *Heurniopsis. Asclepiadàceæ.* One species, *H. decípiens,* N. E. Br., in S. W. Trop. Afr., differing from Huernia in having no outer corona and in other characters. It is a small succulent with decumbent more or less clavate obtusely 4-angled toothed sts. 1–3 in. long: fls. 2–3 together at the middle or toward the top of the st., 1 in. diam. when expanded, outside pale yellow-green spotted and streaked purple, inside brown-red spotted yellow, fetid at night.

HÚLSEA (Dr. G. W. Hulse, of Louisiana, who collected in California). *Compósitæ.* Perennial, biennial or annual herbs native of California, Nevada and north.

Glandular pubescent or woolly herbs: lvs. pinnately lobed or toothed: fls. large, solitary, yellow or purple; involucral bracts free, narrow; style-branches obtuse; pappus of 4 hyaline, lacerated, chaffy scales.—Eleven species. This includes one of many woolly herbs offered by Californian collectors. It grows a few inches high and bears fls. with yellow rays. Treated best as a partial alpine.

nàna, Gray. Fig. 1922 (adapted from Pacific R. R Report). Sts. depressed, leafy at summit, sticky-hairy: lvs. pinnatifid or incised; petiole long-margined: peduncle 1–2 in. long; involucral scales in 2 series; rays 20–30. Calif., north. N. Taylor.†

HUMÀTA (Latin, *of the earth;* referring to the creeping habit of the rhizomes). *Polypodiàceæ.* Ferns of small stature related to Davallia and sometimes included with that genus, with small, thick, deltoid lvs., with the indusium tough, suborbicular or reniform, attached by a broad base and free at the apex and sides.—Some 20 species are known, mostly from the E. Indies. For cult., see *Davallia.*

Tỳermannii, Moore (*Davállia Tỳermannii,* Baker). Bear's-foot Fern. Rootstock wide-creeping, densely covered with linear white scales: lvs. 4–6 in. long, deltoid, 3–4-pinnatifid; lower pinnæ largest, the lowest pinnules cuneate-oblong or deltoid; sori at the base of the ultimate lobes less than a line broad. Cent. China. G.C. 1871:871.

H. heterophýlla, Smith. (Davallia angustata, Wallich.). A small creeping plant with long slender rhizomes and simple entire or slightly lobed lvs. 3–6 in. long, 1 in. broad; fertile lf. narrower, with deep sinuate clefts along the sides. Malaya and Polynesia. —*H. rèpens,* Diels (Davallia alpina, Blume). Small plant: lvs. dimorphic, the sterile 1-pinnate, the pinnæ divided into many small segms.; fertile lvs. reduced nearly to the rachis and midveins of the pinnæ; sori borne on spine-like branches of the latter. E. Asia. L. M. Underwood.

HÙMEA (after Lady Hume). *Compósitæ.* Herbs or shrubs, one of the most popular of which is a half-hardy biennial Australian plant, growing 5 or 6 feet high, cultivated for the grass-like beauty of its large, loose, much-branched, drooping panicles.

Flowers exclusively tubular and hermaphrodite, 1–4 in a small head; involucre narrow, with scarious or petaloid, non-radiating bracts. Three, at any rate, of the 4 other species are shrubs, with fls. in dense corymbs and involucral bracts rigid or petal-like, while in *H. elegans* the bracts are thin and scarious. The genus has no near allies of garden value. It belongs to a group of 6 Australian genera which have no pappus. Humea has nothing of the typical beauty of the common garden composites, since it has no rays, but the common species is a striking plant.

Sow seed from July 1 to September 1. Keep young plants during winter in very cool house in preference to frames, in northern latitudes, on account of losing so much foliage through damping. In spring, or when signs of growth are taking place, repot into larger pots, using a good, rich loam, which has had plenty of manure. They are gross feeders and growers, requiring plenty of water and good feeding. Good plants in 10-inch pots are very ornamental for conservatory or piazza work. The young plants need plenty of light and air, and should be kept nearly dry during the winter. In spring they should be started into growth gradually, and successively repotted until an 8-inch pot is needed. They should not be syringed except when growing rapidly in warm weather. In June the plants can be placed in a subtropical bed that is shielded from high winds, and staked. The foliage has a peculiar and agreeable scent. (A. P. Meredith.)

élegans, Smith. Lower lvs. ovate-lanceolate or oblong, acuminate: st. clasping or decurrent, 6–10 in. long, wrinkled: fls. variously described as brownish red, pink, ruby-red and rose, very numerous, in long loose, gracefully pendulous panicles, much overtopping the rest of the plant. R.H. 1862, pp. 9, 10; 1895, p. 459. S.H. 1, p. 154. *H. álbida,* Hort., is presumably a whitish-fld. form of this species, and should therefore be called var. **álbida.** Var. **gigantèa,** Hort. Much taller than type, reaching 20 ft. in height, having larger lvs. and panicles. The species itself is said by Bentham to attain 5 or 6 ft. or more in Austral. N. Taylor.†

HÙMULUS (Latin name, of doubtful origin). *Moràceæ.* Hop. Two twining vines, with rough, opposite, palmately lobed or divided leaves, grown for ornament and one also for "hops."

Diœcious, the fls. in axillary clusters; staminate fls. with 5 erect stamens and 5-parted calyx, in little drooping tassel-like racemes; pistillate fls. with an entire calyx or perianth closely investing the ovary, which bears 2 long stigmas, the fls. in pairs under large overlapping bracts, the whole making a cone-like catkin which, when becoming very large, is a "hop."—One species in N. Amer. and Eurasia, and one in Japan and Manchuria.

A. *Plant bearing hops,—the pistillate catkin greatly enlarging in fr.*

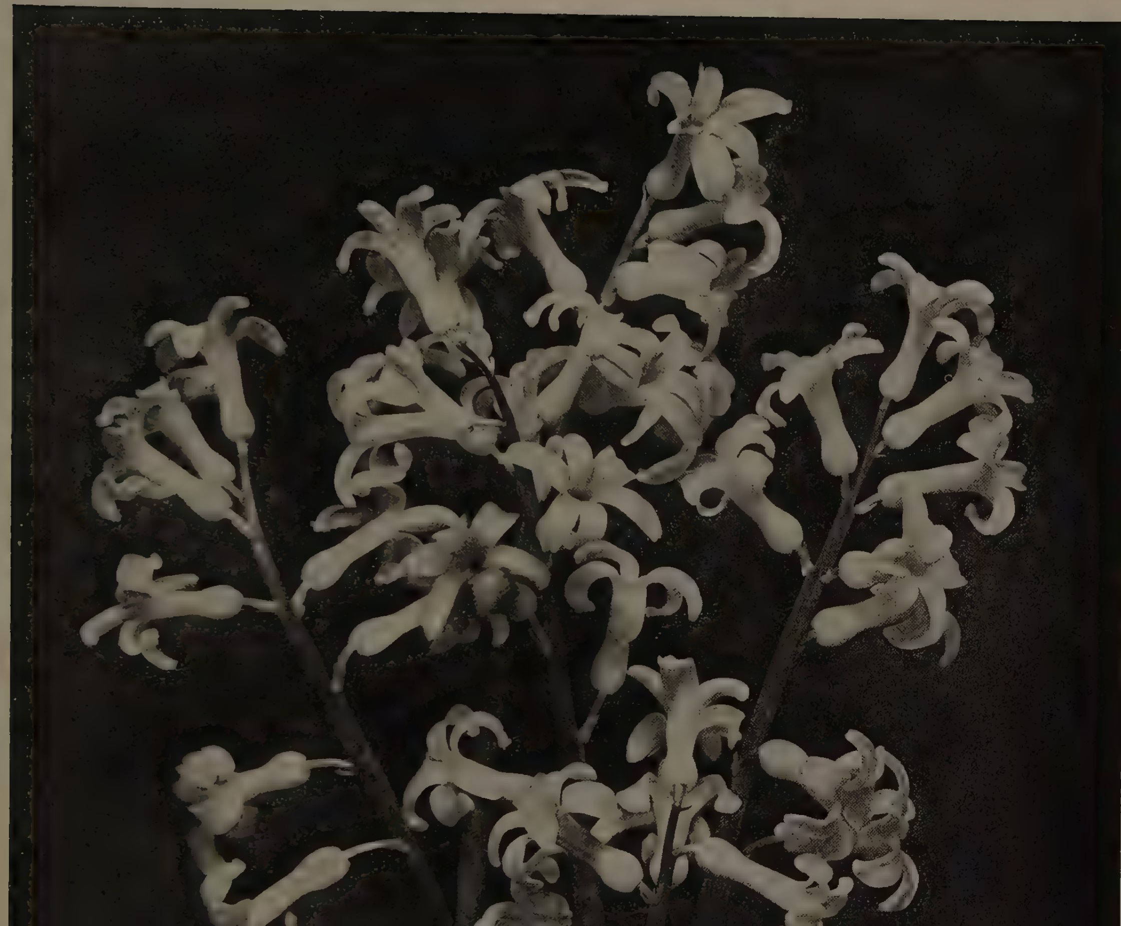
Lùpulus, Linn. Common Hop. Perennial herb: shoots often grow 25–30 ft. long in the season: rough-hairy: lvs. ovate or orbicular-ovate in general outline, deeply 3-lobed (sometimes 5–7-lobed), or the upper ones not lobed, margins strongly and uniformly dentate, petioles long: staminate fls. in panicles 2–6 in. long: hops (mature pistillate catkins) oblong or ovoid, loose and papery, straw-yellow, often 2 in. or more long, glandular and odoriferous.—Native along rivers and in thickets in the northern states and Canada, and southward in the Alleghanies and Rockies; occurs as far south as Fla. and Ariz. Much cult. for "hops," used in brewing, and extensively run wild from cult. plants. The hop makes an excellent arbor or screen plant. Var. **aùreus** has yellow foliage. G.W. 10, p. 501. The hop grows readily from cuttings of the shoots, which spring from the crown; also by seeds, but the latter do not reproduce the particular varieties or strains. As a field crop, the hop is not a horticultural subject, and is not discussed here. See Cyclo. Amer. Agric., Vol. II, p. 380. The Rocky Mt. form, common in Colo. and New Mex., has been separated as var. **nèo-mexicànus,** Nels. & Ckll., and it is in the trade: it has more deeply divided lvs. and more sharply acuminate bracts than the ordinary hop; lf.-segms. from broad-lanceolate to nearly linear, acuminate, with resin particles on the lower surface.

AA. *Plant not bearing hops,—the pistillate catkin not greatly enlarging in fr.*

japónicus, Sieb. & Zucc. Annual (or at least treated as such): foliage very like the last, but usually more deeply cut and not less than 5-lobed: catkins not glandular. Japan, China (perhaps intro.) Manchuria; somewhat run wild from cult. in this country. G.C. II. 24:716.—Intro. to general cult. in 1886, and now one of the most popular climbing herbs. It is a very quick grower, plants 10–20 ft. long coming from seed sown in early May. It is very easy of cult. and usually seeds itself. Var. **variegàtus,** Hort., is the most popular form. Gng. 1:241. A.F. 8:489. The foliage is variously streaked and splashed with white. Seeds of this variety will give a large percentage of variegated forms, and the plants usually show interesting variations. *H. japonicus* is more popular as an ornamental vine than *H. Lupulus,* because it grows so quickly from seeds, and also because it has such interesting variegated forms; but *H. Lupulus* has a distinct charm in its great hanging hops, and the heavy odor is enjoyed by some persons. L. H. B.

HUNNEMÁNNIA (John Hunneman, English friend of botany, died 1839). *Papaveràceæ.* Mexican Tulip Poppy. One yellow-flowered herb closely allied to the California poppy (Eschscholtzia) and of similar garden value, where hardy.

The genus agrees with Eschscholtzia in having much-cut foliage and spreading lobes of the stigma, but differs in having separate sepals instead of the peculiar hood-like calyx of Eschscholtzia, which covers the young fl. like a candle extinguisher: torus scarcely dilated; sepals



LVI. Roman hyacinth.—Hyacinthus orientalis variety.

2, caducous; petals 4, spreading, yellow; stamens many, orange-colored; ovary oblong, attenuated into a short style: caps. 1-celled and 2-valved, prominently 10-nerved; seeds many.—Mex. in the xerophytic regions.

fumariæfòlia, Sweet. Perennial, persisting for several years when planted in Calif., but mostly treated as an annual: lvs. triternately divided: peduncles solitary, terminal; fls. 2–3 in. across; sepals ovate, concave, glabrous, longitudinally striate; petals concave, wavy, broadly obovate or nearly orbicular. B.M. 3061. R.H. 1902:112. Gn. 77, p. 288. Gn.W. 15:443. A.F. 27:579.—Sold as giant yellow tulip poppy. Seed sown early in May in the East give bloom in July, and plants are covered with large yellow fls. until hard frost. The plants have bushy habit and beautiful, feathery, glaucous foliage; 2 ft. The fls. at times stand up like tulips; excellent for cutting. L. H. B.†

1923. Hura crepitans. (× about ½)

HÚNTLEYA (personal name). *Orchidàceæ.* Epiphytal orchids without pseudobulbs, like Zygopetalum.

Leaves several: fls. solitary on long peduncles in the lf.-axils; sepals and petals similar, spreading, the lateral sepals forming a slight chin; lip articulated to the foot of the column, the upper part ovate, concave, narrowed into a broad claw below with a fringed callus; column broadly winged at apex; pollinia 4, upon an ovate stalk.—Species 2, in Trop. Amer.

meleàgris, Lindl. (*Batemánnia meleàgris,* Reichb. *Zygopétalum meleàgris,* Benth.). Lvs. up to 1 ft. long, exceeding the peduncles: fls. about 3 in. across; sepals and petals ovate-lanceolate, acuminate, the base white, the middle portion yellow, the upper part red-brown, yellow-spotted; lip white with a red-brown apex. Brazil. B.R. 25:14. H.U. 1, p. 6.

Búrtii, Pfitz. (*Batemánnia Búrtii,* Reichb. *Zygopétalum Búrtii,* Benth.). Lvs. up to 15 in. long, much exceeding the peduncles: fls. 3–4 in. across; sepals and petals ovate, acute, the base white, followed by a yellow zone, the apex red-brown, yellow-spotted; lip white below, red-brown at apex, the teeth on the disk purple. Costa Rica. B.M. 6003. F.M. 1874:101.

George V. Nash.

HÙRA (South American name). *Euphorbiàceæ.* Trees, cultivated in the tropics and sometimes in greenhouses as curious or ornamental plants.

Leaves simple, alternate, broad, petioled, hairy: fls. monœcious, apetalous; staminate calyx cupulate, truncate or denticulate; stamens generally numerous, in 2–3 whorls; style long, with flat, radiate stigma; ovules 1 to each of the 5–20 cells: fr. large, flat.—Two species of Trop. Amer.

The sandbox tree, *H. crepitans,* is noted for its explosive capsules which, when ripe, throw the seed many feet with a loud noise. The large poplar-like leaves on long petioles give it quite an ornamental aspect, and it is often planted in the tropics of both hemispheres. It may be grown in Florida and California. The abundant milky juice is poisonous. The tree is suited to light loam soil and is propagated by cuttings in sand with heat, under glass.

crépitans, Linn. Sandbox Tree. Monkey Dinner-bell. Fig. 1923. A tree up to 100 ft. high: lvs. broad-ovate, cordate, acuminate, distantly repand-dentate: fls. small, reddish: caps. 3 in. wide, 1½ in. thick, deeply many-ribbed. Trop. Amer. Lyon Horticole, 1907:125.

J. B. S. Norton.

HUSK TOMATO: *Physalis.*

HUTCHÍNSIA (named for Miss Hutchins, of Ireland, who was skilled in cryptogamic botany). Syn. *Hymenólobus. Cruciferæ.* Low, annual or perennial herbs with entire or pinnate lvs.: fls. white, small, sub-corymbose; pedicels elongated: fr. long-oval or lance-shaped; seeds many or only 2.—Eight species in the Medit. region and the colder parts of the Old World, one species being very widely spread. According to some authorities, Hutchinsia is limited to one species. **H. alpìna,** Ait., is a good subject for the alpine garden and is also occasionally used as a border plant. It grows from 1–4 in. high: lvs. pinnate, shining: fls. snow-white, in clusters, blooming from May to June and often through the summer. Cult. in moist half-shady places and prop. by seeds or cuttings. Gn. 72, pp. 31, 278.

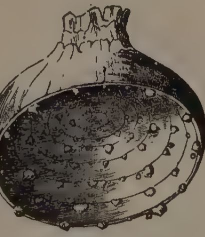
HYACINTH: *Hyacinthus.* **Hyacinth Bean:** *Dolichos.* **Hyacinth, Grape:** *Muscari.* **Hyacinth, Water:** *Eichhornia.*

HYACÍNTHUS (name from Greek mythology). *Liliàceæ.* Hyacinth. Popular hardy spring-flowering bulbs, producing flowers in shades of blue and red, also white; also grown under glass for winter bloom.

Bulbs tunicated: stemless, the lvs. all radical, linear or strap-shaped, the scape simple: fls. in a simple terminal raceme or spike, erect or spreading or pendulous; perianth funnel-shaped to campanulate, nearly or quite equally 6-lobed; stamens 6, attached at the throat or in the tube: caps. nearly globular, 3-grooved or 3-lobed, dehiscent loculicidally; seeds rather few.—Of hyacinths there are something over 30 species, the greater part S. African. Others inhabit the Medit. region, and from this source come the common garden kinds. From related genera, Hyacinthus is distinguished by the funnel-shaped or bell-shaped fl., the throat not constricted, the lobes shorter than or at most not much exceeding the tube, the 6 stamens attached to the tube or throat and the filaments thread-like or dilated at the base. For the general cultural requirements, see *Bulbs.*

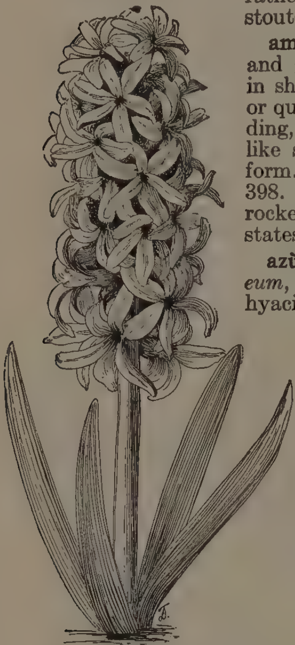
orientàlis, Linn. Common Hyacinth. Fig. 1926. Lvs. 8–12 in. long, ½–1½ in. wide, thick and green: scape 8–18 in. tall, stout, bearing an elongated and dense raceme: perianth about 1 in. long, the tube usually ventricose or swollen, the lobes oblong-spatulate, as long as the tube, in many colors, often double in cult. B.M. 937. B.R. 995. F.S. 23:2399–2400.—The hyacinth has been cult. for some centuries, and it shared some of the early popularity of the tulip in the Netherlands. It is wild in Syria, Asia Minor, Greece and Dalmatia. It is extensively grown in Holland for export to this and other countries, and consequently is commonly known as the Dutch hyacinth. The Roman hyacinth

1924. Cut hyacinth bulb. (×½)



1925. Hollowed hyacinth bulb. (×½)

(Figs. 1927, 1928) belongs to the group represented by var. **álbulus,** Baker (*H. álbulus,* Jord.) and var. **prǽcox,** Voss (*H. prǽcox.* Jord.). These are slender plants with narrow erect lvs., fls. fewer and earlier, white to blush to blue, the tube more slender. Var. *præcox* differs from var. *albulus* in its yellow anthers, rather more ventricose tube and stouter growth.



1926. Common or Dutch hyacinth.

amethýstinus, Linn. Slender and graceful, with light blue fls. in short racemes, standing nearly or quite 6 in. high: fls. small, nodding, bell-shaped, with short teeth-like segms. There is a white-fld. form. Spain. B.M. 2425. B.R. 398. Gn. 47, p. 147.—Good for rockeries. Hardy in the middle states.

azûreus, Baker (*Muscàri azùreum,* Fenzl). Looks like a grape hyacinth (or *Muscari*): 4–8 in. tall, with strongly canaliculate, glaucous lvs.: fls. blue, fragrant, in a dense spike 1 in. long, tubular, with small teeth: distinguished from the genus Muscari by the perianth-segms. being flaring instead of incurved. Medit. region. B.M. 6822. G.C. III. 24:191 (var. *giganteus*). Gn. 75, p. 176.—Hardy in middle states. This species is probably to be called *H. ciliàtus,* Cyrill., or a form of it.

lineàtus, Steud. Low, 2–4 in. high: lvs. 2 or 3, oblong-lanceolate, falcate, about equaling the scape: fls. small (⅙in. or less long), 6–12 in a raceme 1 in. long, blue, campanulate, ascending. Asia Minor. Gt. 1887, p. 446. G.C. III. 29:103; 39:210. Gn. 76, p. 169. J.H. III. 65:203 (as *H. azureus* var. *lineatus*).

fastigiàtus, Bertol. (*H. Pouzòlzii,* Gay). A delicate species, with very narrow lvs., scape 3–5 in. high and shorter than the lvs.: fls. few, in a loose cluster, ¼–⅓in. long and light blue (a white form), with oblong-lanceolate segms. longer than the tube. Corsica. B.M. 6663.—Hardy in S. New England. Has the look of *Scilla verna.*

H. cándicans, Baker=Galtonia. Gn. 75, p. 80. G. 2:546.—*H. romànus,* of Linnæus, is not the H. romanus of horticulturists (which is the Roman hyacinth, a form of H. orientalis). Linnæus' species is a blue-white, scilla-like plant (see B.M. 939, as Scilla romana).

L. H. B.

Culture of the hyacinth.—The perfection of the hyacinth flower depends largely on the strength of the roots, and as the plants make all their root-growth in autumn, the bulbs should be planted early,—say from the beginning to the middle of October. Any good garden soil suits, provided it is well drained. The ground should be carefully prepared by spading to a depth of 20 inches, so that the roots may pass straight through it to their full development of 12 or 16 inches. If the soil is naturally stiff, it may be lightened by the addition of sand, and if the beds have been occupied by other plants during the summer, some clean old cow-manure, well worked in, is recommended. Horse-manure should not be used.

The bulbs should be planted 6 inches deep (to the bottom of the bulbs) and very uniformly, to insure simultaneous flowering. The ground having been prepared as above, perhaps the best way is to remove 3 or 4 inches of the earth, level the bed carefully with the rake and set the bulbs in it 5 or 6 inches apart each way, pressing them in firmly, and then covering them evenly with the earth that has been taken out. When winter sets in, the beds should be covered with 2 inches of dry litter or coarse manure. As soon as the shoots appear above ground in the spring, 1 inch of this covering should be removed and the remainder when danger from late frosts is past.

For large beds and borders, second-size named hyacinths are used to a great advantage. The flower-spikes are not so large as from the first-size bulbs, but the latter when in bloom in the open usually become top-heavy and are often blown down by wind, while the flowers of the second-size bulbs stand more erect and last longer.

Forcing in pots.

For growing indoors in pots, large, solid bulbs should be chosen, and potted singly in 5-inch pots in a rich compost of loam, leaf-mold and sharp sand. A few pieces of broken pot being placed in the bottom for drainage, the pots should be filled lightly, and the bulbs pressed into the loose soil till only the apex remains above the surface. The pots are then buried to a depth of 8 or 10 inches in the open ground or in a frame for seven or eight weeks, till the roots are developed fully and the sprout is about 1½ inches above the bulb. When taken inside, they should be kept in subdued light, at a temperature of about 50°, until the sprout has assumed a vigorous green color. Florists who force large numbers for winter decorations set them under the greenhouse benches for about two weeks, and then force them in a temperature of 70°. A greater heat than this attenuates the growth and weakens the color. Syringing with water twice a day is recommended, and as the flower-spike develops, weak manure-water is helpful. The slower hyacinths are forced, the finer and more lasting will be the bloom. Bulbs wanted in flower for Christmas should be potted in September, and for a succession later, at intervals as desired. Single hyacinths are handsomer and force better than the double, although a few of the latter may be recommended. The following are among the best adapted for forcing and are largely grown by American florists:

Single blue.—Grand Maitre, deep lavender-blue. Czar Peter, light blue. King of the Blues, dark blue. Leonidas, clear blue. Queen of the Blues, light blue. Regulus, porcelain-blue. Schotel, pale blue.

Double blue.—Bloksberg, porcelain-blue. Van Speyk, lilac-blue.

Single white.—Angenis Chistina, pure white. Baroness van Thuyll, pure white. Grandeur a Merveille, blush-white. La Grandesse, pure white. L'Innocence, pure white. Madame Van der Hoop, pure white. Mimi, blush-white. Paix dé l'Europe, pure white.

Double white.—La Tour d'Auvergne, pure white. Isabella, blush-white.

Single red.—De Wet, light rose. Gertrude, bright pink. Gigantea, bright rose. Lady Derby, lovely pink. La Victoire, brilliant scarlet-red. Moreno, waxy pink. Norma, delicate waxy pink. Robert Steiger, crimson.

1927. Roman hyacinth.

Double red.—Bouquet Tendre, crimson. Noble par Merite, deep rose.

Single lilac.—Sir William Mansfield, lilac-mauve.

Single yellow.—King of the Yellows, deep yellow. Yellow Hammer.

Double yellow.—Goethe. Bright yellow.

Miniature hyacinths, or "Dutch Romans," are small-sized bulbs of the ordinary Dutch hyacinths. They are excellent for growing in groups in bowls, pans or flats, planted close together and treated the same as the large hyacinths when grown in pots.

Culture in glasses.

Some of the single hyacinths may be grown very satisfactorily in water. Special glasses for the purpose can be bought from the seedsmen. They should be filled with pure water and the bulb so placed that its base barely touches the water. The glasses must then be placed in a dark closet or cellar till sufficiently long roots have developed and the main flower shoot is about 3 inches tall. This usually requires eight to ten weeks. Thereafter they may gradually be brought into the light. An airy, sunny situation and a temperature of about 60° regularly maintained will insure the best results. The glasses should be kept filled by adding water occasionally as required. A small piece of wood charcoal placed in the glass tends to keep the water pure and sweet.

1928. Roman hyacinth.

The following varieties are especially suited for glasses: Lady Derby, pink. Lord Macaulay, deep rose. Mina, pure white. L'Innocence, pure white. La Victoire, brilliant red. Grand Maitre, blue. Grand Lilas, light blue. King of the Blues, dark blue. Schotel, finest light blue. Mimi, blush-white. MacMahon, pure yellow. Moreno, deep rose. Lord Balfour, lilac tinged violet.

Roman hyacinths.

Instead of one large truss from each bulb, the Roman hyacinth produces three or four smaller but more graceful flower-spikes. The bulbs arrive in America in August, and by successive pottings they may be had in flower from November till May. They require the same forcing treatment as the larger hyacinths, but three or four bulbs may be planted in a pot. The florists use wooden flats instead of pots, setting the bulbs close together, forty or fifty in a flat. By reason of its beauty and exquisite fragrance, its earliness and easy culture, the white Roman hyacinth is the most popular of winter-blooming plants. Several millions of these bulbs are grown annually by the florists of the large cities for winter cut-flowers.

Within the last few years, large quantities of Dutch hyacinths have been planted and grown for one year in the south of France, where they ripen off several weeks earlier than in Holland. Consequently, these hyacinths can be forced in bloom two to three weeks earlier than the ordinary Holland-grown stock of the Romans.

The propagation of hyacinths.

With the exception of the Roman hyacinths (which come from the south of France), the world's supply of hyacinth bulbs is produced in Holland. The soil and climate of that country seem to be peculiarly suitable for bulb-growing, which has been one of the leading industries there for 200 years. The bulbs intended for next year's market are planted in October in carefully prepared, richly manured land, and protected over winter by a thick covering of reed or litter. The flowers are cut when in full bloom in the spring. By July the bulbs are fully ripened, and are taken out of the ground by hand, dried, cleaned and assorted into three grades of quality, according to size. Early in August they are ready for shipping. Overgrown or unshapely bulbs are reserved for propagating. As soon as these are taken out of the ground, three deep cross cuts are made with a sharp knife in the bottom of each bulb. They are then set out, bottom upward, and covered with loose soil for two or three weeks, during which time the cuts open out and the wounds are healed. They are then taken up and kept spread out on tables in storehouses till October, when they are planted out. When lifted next June, nothing of the parent bulb remains but dry skins, on the edges of which twenty to thirty offsets are fastened. These bulblets are picked off by hand and planted out in autumn, just like large bulbs. This process of planting in autumn and taking up in summer for a two months' rest is repeated for four or five years, till the bulbs have attained to marketable size. Another method of propagating is to hollow out the bottom of the bulb smoothly to a point in the center. More offsets are secured in this way, but they are smaller and take a year or two longer to reach maturity. These methods are illustrated in Figs. 1924, 1925.

New varieties are obtained from seed, but as the present leading varieties have attained a very high degree of perfection in form and in color, few seedlings show marked improvements on existing sorts. New varieties are also produced by "sporting," that is, one plant spontaneously assumes a new and different character from the remainder of the stock and from this one plant new stocks are grown. In this way the beautiful light rose variety DeWet sported from single blue Grand Maitre, while single purple Lord Balfour first appeared in a stock of the deep rose Moreno, and so on.

The tendency to produce new varieties should be restricted to distinctive forms and colors. Many of so-called new varieties recently introduced are merely slight alterations in form or color of the parent bulb, not sufficient in appearance to justify calling them new sorts, merely increasing the list of named sorts for advertising or selling purposes. J. M. Thorburn & Co.

HYÆNÁNCHE (Greek, referring to its native African use as a hyena poison). *Euphorbiàceæ.* Small tree, sometimes grown in greenhouses. Lvs. whorled or sometimes opposite, simple, entire: fls. diœcious, apetalous, in axillary clusters; sepals in staminate fls. 5–12, stamens numerous: ovules 2 in each of the 3–4 cells. The single species is **H. capénsis,** Pers. (*Toxicodéndron capénse,* Thunb. *H. globòsa,* Lamb.). HYENA POISON. A much-branched tree, 5–6 ft. high: lvs. linear to oblong, base cuneate, apex rounded, glabrous: caps. subglobose. S. Afr. It is adapted to well-drained light soil, and is prop. by cuttings in sand under glass. During its rest-period water should be given sparingly. J. B. S. NORTON.

HYBÁNTHUS (from Greek meaning *hump-backed flower*). *Violàceæ.* Species about 50, in Old and New World, mostly in tropical and subtropical parts. One species native to the E. U. S., is sometimes listed: it is an herbaceous perennial 1–2 ft. high, with mostly oblong, narrowly acuminate lvs. 3–5 in. long, and small nodding greenish fls. solitary or in pairs in many of the lf.-axils: sepals linear and equal; petals mostly nearly equal in length, connivent nearly their entire length, the lower one much larger, saccate at the base, emarginate at the broad apex; stamens with broad connectives wholly connate into an ovoid sac open only between the free tips, a rounded or 2-lobed scale-like gland adnate to the base anteriorly.

cóncolor, Spreng. (*Ionídium cóncolor,* Benth. & Hook. *Sòlea cóncolor,* Ging. *Cubèlium cóncolor,* Raf.). May, June. Moist woods and ravines, Ont. to Ga. and West. F. W. BARCLAY.

HYBRIDS are the products of crossing between species. Of late, the word hybrid has been used by most writers to comprise all crosses, whether between species or varieties. The justification of this usage is the fact that there are no hard and fast lines between varieties and species, and therefore that hybridism in the old sense is incapable of exact delimitation. The opponents to this usage, however, contend that so long as it is customary to speak of species and varieties as different classificatory categories, it is equally allowable and useful to speak of hybrids as between species and of cross-breeds as between varieties; moreover, historical custom favors this usage. Common-language terms rarely if ever express absolute or ideal truth: they grow up by custom. Whenever new ideas and discoveries render them inexact, it may be quite as well to invent new terms as to give new and technical meanings to old terms which are thoroughly established in literature. The word hybrid has always been a specific term, and it were a pity now to make it a generic one, particularly since there is a well established generic term. The generic word, both substantive and verb, is *cross.* Specific kinds of crosses are hybrids, between species; cross-breeds, between plants of the same species; half-hybrid, between a species and a variety of another species; bigener, between plants of different genera. There are technical terms to designate the various kinds and degrees of crossing. The word hybrid has now become so flexible, however, and other standards of measurement are so much in vogue, that these special terms are little used.

It was formerly held that inability to make fertile hybrids is proof that the forms are distinct species; and contrarywise, that plants which make fertile crosses are of one species. Hybridization has also been made a test of genera. These notions are now given up, for crossing and classification belong to two unlike categories of facts. Species and genera are not entities in themselves, but are mere artificial groups made by men for their convenience when writing and speaking of living things. Crossing is a biological phenomenon.

Hybrids are unusual facts in nature; that is, they are rare compared with the whole number of plants. On the other hand, cross-breeds are usual. Most flowers are so constructed as to favor cross-pollination. Cross-breeding is one of the prime means of inducing slight variations and of invigorating a type. Upon the variations which arise from crossing and other means, natural selection operates in the production of new forms. But it is significant that these new forms usually come about slowly and gradually. It is the desire of the cultivator to produce new forms quickly and of pronounced distinctness. He therefore employs crossing between unlike types, or species, hoping thereby to secure wider departures. In nature, the cross-breed is the beginning of a process of breeding: it starts off the variation. Man is often tempted to look upon the hybrid as the end. If the products of a given cross are not to his liking, he throws them away and tries again. The most expert plant-breeders, however, now hybridize to get a "break," and thenceforth depend chiefly on selection to realize their clear-cut ideals, particularly in seed-propagated plants.

To man hybrids are of no value unless they can be propagated. By seeds they usually vary immensely: it is difficult to "fix" them so that they will come true. By cuttings or layers or division, however, the character of the parent may be propagated with practical certainty: the original plant is divided, and the parts are put on the market. Nearly all commercial hybrids are of plants which are thus propagated by asexual parts: Kieffer pear, hybrid grapes, Wilson blackberry, Wild Goose plum, cannas, roses, begonias, anthuriums, fuchsias, pelargoniums, rhododendrons. Since the hybrid is variable when propagated by seeds, continued selection, or plant-breeding, must be employed to fix and establish a desirable type.

It is thus seen that hybridization rarely gives rise to dominant horticultural seed-races, but rather to an individual plant which may be disseminated by some divisional means of propagation. The seeds of hybrids—as of the modern cannas—may give rise to good varieties, and they may not; but these new varieties are, in their turn, usually propagated by means of asexual parts if they are to be kept true.

Practically there is no certainty in hybridization. Rarely can a man picture to himself an ideal variety, and then by means of hybridization produce it. He hybridizes plants which possess some of the characteristics of the desired or ideal variety, and then takes his chances. True plant-breeding sets an ideal, and then reaches it by working along certain definite lines. It seeks first to secure a variation in the desired direction: this may be secured by means of crossing, change of soil, modification of food-supply, and other changed conditions. It seeks, then, to preserve or augment the form by means of definite selection.

We are not yet able to formulate positive laws of hybridization. Every hybrid is a law unto itself. By the study of many examples of hybridization, one is able to construct an average of probabilities as to what will or what will not occur in a given case: but the given case may contradict all the probabilities without apparent cause. Hybridization is an empirical subject.

One cannot tell what species will or will not hybridize except by trying. Hundreds of species have been tried, and for them the knowledge is more or less exact. Plants hybridize most freely which are the subjects of much care and coddling: the orchids are the best examples. In these groups, hybrids are chiefly fanciers' plants, valuable often only because they are hybrids or are rare and curious. One cannot tell beforehand whether the products of any hybridization will be exact intermediates, or in what way or degree they will carry over or blend the parental characters. As a rule, the more closely akin the species, the more perfect will be the blending or amalgamation of the two. See *Breeding of Plants,* Vol. I.

The literature of hybridization is extensive but scattered. The possibilities of hybridization as a factor in plant-breeding are presented in many aspects in the "Hybrid Conference Report" of the Royal Horticultural Society, London, 1900. There are special books devoted to orchid hybrids (see *Orchids*). See an excellent paper by Swingle and Webber, "Yearbook of the United States Department of Agriculture," 1897; papers in "American Gardening," 1899, pp. 397, 413, 431; Bailey & Gilbert's "Plant-Breeding;" De Vries' "Plant-Breeding."

L. H. B.

HYDRÁNGEA (Greek, *hydor*, water, and *aggeion*, vessel; alluding to the cup-shaped fruit). *Saxifragàceæ.* Ornamental woody plants, grown chiefly for their showy white, pink or blue flowers.

Deciduous shrubs: lvs. opposite, without stipules, petioled, serrate, sometimes entire, rarely lobed: fls. perfect, in terminal panicles or corymbs, often with sterile marginal fls.; calyx-lobes and petals 4–5; stamens usually 10; ovary inferior or half-inferior; styles 2–5, short: caps. 2–5-celled, dehiscent at the base of the styles, with many minute seeds.—About 35 species in N. and S. Amer., Himalayas and Cent. and E. Asia, of which more than 20 occur in China; for a key to the Chinese species, see Rehder, Synopsis of the Chinese Hydrangeas (in Sargent, Plantæ Wilsonianæ 1:34–41).

The hydrangeas are highly ornamental mostly low shrubs, rarely vines climbing by rootlets, with medium-sized or rather large leaves and small white, bluish or pinkish flowers in corymbs or panicles, bearing usually marginal sterile flowers, with enlarged showy sepals, or in some varieties all the flowers are sterile and enlarged. *H. paniculata* is the hardiest of all, but *H. arborescens*, *H. radiata*, *H. xanthoneura* and *H. Bretschneideri* are also almost hardy North, while *H. quercifolia* and *H. petiolaris* are hardy as far north as Massachusetts, and *H. involucrata*, *H. opuloides*, *H. Sargentiana*, *H. heteromalla* and *H. Davidii*, are still more tender, and cannot be grown outdoors North.

They grow best in a rich, porous and somewhat moist soil and thrive well in partly shaded positions, but flower more freely in full sun if they only have sufficient moisture. All hydrangeas are well adapted for borders of shrubberies, and *H. paniculata* and *H. opuloides*, especially the varieties with sterile flowers, are very showy as single specimens on the lawn. In warmer climates the latter is sometimes used for ornamental hedges (see G.C. III. 24:337, 456); but it is not hardy in the North. These and also most of the other species should be pruned in fall or early spring, and the branches of the previous year cut back to one to three pairs of buds, according to the growth of the branches and the desired size of the panicles; if only slightly pruned, the panicles will be many but small. Sometimes they are cut back every year almost to the ground and produce then enormous panicles, which, however, usually need artificial support and lack the gracefulness of less severely pruned plants. *H. paniculata* var. *grandiflora* can be grown into a small standard tree; for this purpose vigorous young plants should be selected and planted in rich soil, and cut down to the base. The strongest shoot of each plant will attain by fall the height of 4 to 6 feet, if freely manured and watered during the summer; in autumn, all the weaker branches are cut off, and in colder climates the plants should be lifted and stored in a frost-proof pit or cellar, since the wood is usually not sufficiently ripened to withstand severe frost. In the following year the top of the stem is allowed to branch. The weaker basal shoots may be pegged down to make new plants. Strong-growing varieties of *H. opuloides* may be treated in the same way if standard plants are desired.

The method of winter protection of hardy hydrangeas adopted around Newport, Rhode Island (and possibly other places) may be worthy of mention. In the case of individual specimens, after the leaves have dropped in the fall, the branches are tied together and the plant covered with a box having open ends. The box is then filled with earth. When the plants are growing together in a bed or border, they may be treated in a similar way by placing boards along the side of the bed, to assist in retaining the earth that is used as a covering material. If, after the branches are tied, they are bent over somewhat, a saving of labor is effected by reason of a smaller quantity of earth being sufficient to cover them. (Montague Free.)

H. opuloides, which cannot withstand much more than 10° of frost, is in the North much grown as a pot-plant, especially the more showy varieties with large heads of sterile flowers, and is extensively used for outdoor decoration during the summer. Late in fall, when the leaves have fallen after frost, the plants are moved to a frost-proof cellar and kept rather dry until spring, when they are repotted in new soil and the growth of last year cut back to one or two pairs of buds. As a suitable soil may be recommended a mixture of loam, leaf-mold and sand, with ground bone, dried cow-manure or some other kind of manure added. During the summer a liberal supply of water should be given, also occasionally applications of liquid manure, until the flowers have developed. They may also be planted in the open ground during the summer, lifted late in fall with a large ball of earth, stored over winter in a coldframe or pit and planted out again in spring; this will not injure in any way the profusion of flowers. In certain kinds of soil the pink hortensias show a tendency to turn blue, and perhaps this can be caused by adding iron filings or alum to the soil. *H. opuloides* is also a valuable plant for forcing, and is much grown for Easter, especially the var. *otaksa*, on account of its dwarfer habit. Handsome pot-plants can be grown in one year from cuttings. In February or March cuttings are inserted in the propagating-house with slight bottom heat, and planted in small pots as soon as they are rooted. During the summer they may be easily grown in pots and plunged outdoors in coal-ashes or in any kind of porous soil, transplanted several times, and freely watered and occasionally manured; or they may be planted out in rich soil, exposed to the full sun, where water should be liberally given and now and then an application of liquid manure. Last of September they should be repotted in 8-inch pots, kept shady some days until established, and afterward exposed to the sun. After the first frosts they may be brought into a cool greenhouse. If intended to have them in flower for Easter, they should be transferred not later than the fore part of January into a warmer house, with a temperature gradually rising from 50° to 60°; the plants should be freely watered, and about once a week an application of liquid manure given until the flower-buds are developed. The flowers should be almost fully developed some time before they are desired, that they may be hardened off in a cooler house, since overforced plants are likely to collapse if exposed to sudden changes of temperature. After

1929. Summer cutting of Hydrangea paniculata.

flowering, the plants are pruned and repotted or planted out and treated as above described for cuttings, or they may be thrown away and another set of plants raised from cuttings.

H. petiolaris is a handsome climbing plant for covering walls and trunks of trees, and grows well in the shade, but flowers freely only in the full sun.

The hydrangeas are readily propagated by cuttings of half-ripened or nearly ripe wood under glass in summer (Fig. 1929); also by hardwood cuttings, layers, suckers or division of older plants. *H. quercifolia* is best propagated by suckers or by layers of growing wood put down in summer. Rarely increased by seeds, which are very small, and should be sown in fall in pans or boxes and only slightly covered with soil.

A. *Shrubs erect or spreading: stamens 10: petals expanding.*

B. *Infl. pyramidal.*

1. **quercifòlia,** Bartram. Shrub, with spreading branches, to 6 ft.: young branches densely ferrugineously tomentose: lvs. long-petioled, roundish or broadly ovate, pinnately lobed with serrate lobes, glabrous above at length, whitish tomentose beneath, 4–8 in. long: panicle 4–7 in. long; fls. pinkish white, the sterile ones turning purple; styles 2: caps. with the calyx-teeth at the apex. June. Ky. to Ala. and Fla. B.M. 975. Gng. 2:305. Gn.M. 2:66. G.C. II. 22:369. Gn. 27, p. 199. G. 27:389. G.W. 5, p. 109. M.D.G. 1913:517.

2. **paniculàta,** Sieb. Shrub or small tree, to 30 ft., with dense globose head: lvs. elliptic or ovate, acuminate, serrate, sparingly pubescent above, more densely on the veins beneath, 2–5 in.: panicle 6–12 in. long; fls. whitish, the sterile ones changing later to purplish; styles 3: caps. with the margin of the calyx about at the middle. Aug., Sept. Japan, China. S.Z. 61. F.E. 15:501; 34:387. F.R. 21:9. G.W. 2, p. 114; 12, p. 366. G.C. III. 9:553. Gn. 59, p. 181; 75, p. 548; 76, p. 5. Mn. 9:75. The following varieties are cult.: Var. **floribúnda,** Regel. Panicles large, with more and larger sterile fls. Gt. 16:530. Var. **grandiflòra,** Sieb. (var. *horténsis*, Maxim.). Fig. 1930. Almost all fls. sterile; panicles very large and showy. F.S. 16:1665, 1666. Gn. 10:37; 38, p. 569; 54, p. 376; 64, p. 407; 72, p. 560. R.H. 1873:50; 1899, pp. 130, 131. Mn. 8:119. A.G. 18:313. Gng. 3:357; 5:3. F.E. 8:214. S.H. 1:174. G.M. 39:728; 46:794. Gn.M. 2:67. A.F. 17:194, 517. C.L.A. 7:43. G.W. 8, p. 210; 15, p. 454. G.Z. 10:80. Var. **prǽcox,** Rehd. Fig. 1931. Almost like the type, but flowering about 6 weeks earlier, in the middle of July; sepals usually elliptic. G.F. 10:363 (adapted in Fig. 1931). The late-flowering typical form is sometimes called var. **tardìva,** Hort.—*H. paniculata* var. *grandiflora* is the common hydrangea of lawns. It is seen to best effect when planted close in front of heavy shrubbery. Cut back rather heavily in early spring.

1930. Hydrangea paniculata var. grandiflora.

BB. *Infl. corymbose, flat or globular.*

C. *Ovary partly superior; hence caps. ovoid, with the margin of the calyx about the middle; styles usually 3: sterile fls. present.*

D. *Fertile fls. white.*

E. *Lvs. white-tomentose below.*

3. **heteromálla,** Don (*H. vestìta*, Wall. *H. pubéscens*, Decne.). Shrub, to 10 ft.: petiole deeply grooved and margined, red; lvs. ovate, acuminate, densely setosely dentate, almost glabrous above, densely whitish-tomentose beneath, 4–8 in. long: cyme 5–8 in. broad, with bracts; sepals of sterile fls. elliptic or obovate, acute or mucronulate: caps. with the calyx above the middle. June, July. Himalayas. F.S. 4:378—79. G.C. II. 22:617. G.M. 50:859.

EE. *Lvs. villous or nearly glabrous below.*

4. **Brétschneideri,** Dipp. (*H. vestìta* var. *pubéscens*, Maxim. *H. pekinénsis*, Hort.). Fig. 1932. Shrub, to 8 ft.: last year's branchlets with chestnut-brown bark peeling off in thin flakes: petioles not margined; lvs. ovate or elliptic-ovate to oblong-ovate, acute or acuminate, serrate with short callous teeth, more or less pubescent beneath, 3–5 in. long: cymes similar to the former but smaller and denser; sepals roundish, obtuse: caps. with the calyx near the middle. July. N. China. G.F. 3:17 (adapted in Fig. 1932); 6:396. G. 27:387. Gng. 16:305. G.W. 9, p. 541. Var. **glabréscens,** Rehd. (*H. serràta*, Koehne, not DC.). Lvs. smaller, elliptic, more coarsely serrate and only sparingly pubescent.

5. **xanthoneùra,** Diels. Shrub, to 15 ft.: last year's branchlets with close chestnut-brown bark marked with conspicuous lenticels: lvs. elliptic to elliptic-oblong, abruptly acuminate, serrate, glabrous and bright green above, marked with more or less conspicuous yellow veins, light green below and glabrous or slightly pubescent on the veins, 4–7 in. long; petioles ½–1¼ in. long: corymbs rather loose, convex, 5–10 in. across; sterile fls. 1¼–2 in. across, with oval obtuse sepals. July. W. China. Var. **Wílsonii,** Rehd. Last year's branchlets grayish or pale brown: lvs. somewhat narrower, glossy above. W. China. M.D.G. 1912:26. The handsomest form of the species. Var **setchuenénsis,** Rehd. (*H. Brétschneideri* var. *setchuenénsis*, Rehd.). Last year's branchlets light brown: lvs. to 8 in. long and to 4 in. broad, villous below. W. China.—This species and its varieties have proved hardy at the Arnold Arboretum. It is very similar to the preceding species, but easily distinguished by the close bark.

DD. *Fertile fls. bluish or pink: lvs. glabrous or pubescent only on the veins below.*

6. **Dàvidii,** Franch. Shrub, to 6 ft.: young branchlets finely appressed pubescent, older light brown: lvs. elliptic-lanceolate or ovate-lanceolate, long-acuminate, cuneate at the base, sinuately serrate, yellowish green and nearly glabrous above, pubescent on the veins below, 3½–6 in. long: corymbs loose, convex, sometimes nearly paniculate, 6–8 in. across; sepals and petals lanceolate; sterile fls. about 1½ in. across, with 3 or 4 sepals: caps. with the margin of the calyx about or slightly below the middle. W. China.—Handsome species with its large loose corymbs of blue fls.; tender.

7. **opuloìdes,** Koch (*H. horténsis,* Smith. *H. Horténsia,* DC. *H. japónica,* Sieb.). Shrub, to 8 ft., almost glabrous: lvs. ovate or ovate-elliptic, acuminate or acute, coarsely serrate, 5–8 in. long: fls. in large cymes without bracts, white, bluish or pink, few or all of them sterile.—The greenhouse hydrangea. June, July, but blooming in winter under glass. A large number of varieties have been intro. from Japan and China, where this species has been extensively cult. for many centuries, and where it is native. The following are some of the best known. They may be divided into 3 groups:

(1) *Japonica group: cymes flat, with sterile and fertile fls.*

Var. **acuminàta,** Dipp. (*H. acuminàta,* Sieb. & Zucc. *H. Buérgeri,* Sieb. & Zucc.). Lvs. ovate-lanceolate, acuminate, sparingly appressed-pubescent: sterile fls. with elliptic entire sepals, usually blue. S.Z. 56, 57. Var. **Azísai,** Dipp. (*H. Azísai,* Sieb.). Lvs. elliptic-ovate, glabrous: sterile fls. with obovate sepals, long-pedicelled, overtopping the fertile ones. S.Z. 51. Var **Belzònii,** Schneid. (*H. Belzònii,* Sieb. & Zucc. *H. japónica* var. *cærùlea,* Hook. *H. japónica* var. *cæruléscens,* Regel). Of dwarfer and stouter habit: lvs. ovate or obovate, short-acuminate, glabrous, somewhat thick: sterile fls. whitish, pinkish, or bluish, with rhombic, usually entire sepals. S.Z. 55. B.M. 4253. Here belongs also var. *Imperatrice Eugenie* with pink fls. R.H. 1868:471. Var. **japónica,** Schneid. (*H. japónica,* Sieb.). Lvs. ovate to elliptic, acuminate, glabrous: sepals broadly ovate, toothed, pink. S.Z. 53. B.R. 30:61. R.H. 1874:90 (as *H. acuminata*). Var. **macrosépala,** Dipp. Differs from the former only by its larger sepals. Gt. 15:520. Var. **Màriesi,** Hort., seems also not much different, but has somewhat broader lvs., and the pink sterile fls. are very large. Gn. 54: 390. G.C. III. 23, suppl. May 28. G. 26:409. G.M. 41:347; 46:577, 578. G.W. 6, p. 557; 9, pp. 413, 414. Var. **Veìtchii,** Hort. Similar to the preceding variety, but sterile fls. pure white, 3–3½ in. across. G. 26:175. Var. **Lindleyàna,** Rehd. (*H. rosálba,* Van Houtte. *H. horténsis* var. *Lindleyàna,* Nichols.). Lvs. ovate or elliptic-ovate, acuminate, sparingly hairy: sepals dentate, ovate or broadly ovate, white and pink, or white changing to pink. F.S. 16:1649, 1650. R.H. 1866:430. Gn. 46:466. Var. **serràta,** Rehd. (*H. serràta,* DC. *H. Thúnbergii,* Sieb. & Zucc. *H. cyànea,* Hort.). Lvs. elliptic or ovate, narrowed at both ends, serrate, sparingly appressed-hairy, 1½–3 in. long: cymes small, 3–4 in. broad; fls. pinkish or bluish; sepals roundish, obtuse or emarginate. S.Z. 58. G.C. 1870:1699.

(2) *Hortensia group: cymes globose, with almost all fls. sterile.*

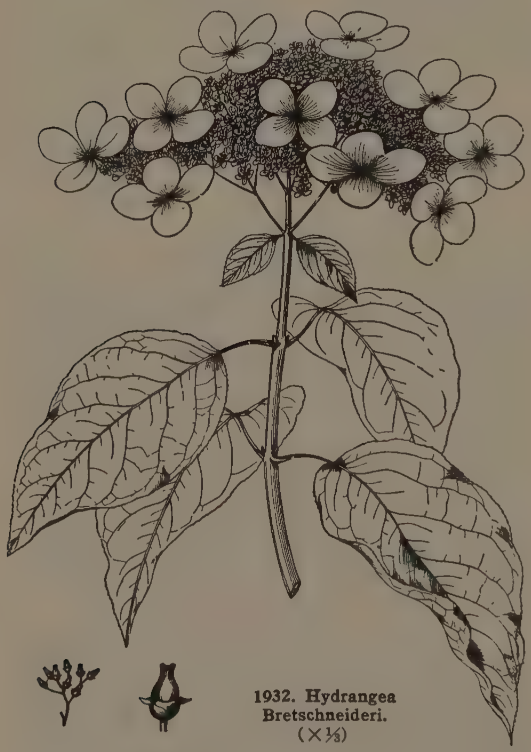
Var. **cyanóclada,** Dipp. (*H. mandshúrica,* Koehne. *H. Horténsia* var. *nìgra,* Arb. Kew. *H. nìgra,* Carr. *H. rámulis coccíneis* and *H. rámulis píctis,* Hort.). Branches dark purple or violet, often almost black: lvs. ovate-elliptic, acute: cymes large, with purple peduncles; sepals pink or bluish, obovate. A.F. 5:361. Var. **Horténsia,** Dipp. Lvs. large, elliptic, glabrous: sepals broadly ovate, entire, usually pink. This is the form which first came into cult. outside of Japan and China, and is said to have been intro. from China to England in 1790, by Joseph Banks. B.M. 438. G.C. III. 24:45; 52:251. Gn. 45, p. 12; 50, pp. 123, 256, 367; 52, p. 281. F.E. 18:277. A.G. 1900:695. Gn.M. 2:66. G. 4:223; 15:139; 20:441. Var. **plèna,** Regel. Similar to the preceding, but sepals toothed. Var. **otáksa,** Dipp. (*H. otáksa,* Sieb. & Zucc.). Fig. 1933. Dwarfer, but of vigorous growth: lvs. obovate, short-acuminate, rather thick, glabrous: sepals obovate, entire, pink or blue. S.Z. 52. F.S. 17:1732, 1733. Gn. 50: 122. R.H. 1868:450. Mn. 5, p. 105. A.G. 11:415; 19: suppl. Feb. 12; 44:415. A.F. 10:1015. F.E. 9:52, 401. Gng. 5:161; 6:7. Here belong also the following 4 forms: Var. *otáksa monstròsa,* Lambert, with very large heads. S.H. 2:517. G.W. 13, p. 43. Var. *otáksa monstròsa nàna,* Brunnemann. A very dwarf form of the preceding. M.D.G. 1909:235. Var. *ròsea,* Veitch. Lvs. smaller, more finely serrate: fls. deep rose-color or bright blue. Gt. 53:1533 (rose). R.H. 1904:544 (blue). Gn. 50:122. G.W. 7:582. Gn.W. 22:493. Var. *Thomas Hogg,* Hort. Lvs. elliptic, or ovate: heads pure white, large. One of the best as a pot-plant. It is also to be recommended for outdoor cult., as it is one of the hardiest.—Some beautiful forms mostly of hybrid origin of the Hortensia group have recently appeared in the trade, of these may be mentioned here: *Madame E. Mouillère,* white fls. with crenate close sepals. R.H. 1912, p. 62. M.D.G. 1911:41. G.C. III. 49:204. Gn. 75, p. 180. *Beauté Vendomoise,* fls. very large, with clawed and crenate sepals, fls. therefore open in the center. R.H. 1912, p. 63. *Professor D. Bois,* fls. deep rose, large, sometimes 5 in. across. R.H. 1912, p. 325. *Eclaireur,* fls. large, rose-carmine, said to be the most deeply colored form. *Mademoiselle Renée Gaillard,* fls. white with dentate sepals. M.D.G. 1911: 38, 39. *Avalanche,* fls. pure white. *Genérale Vicomtesse de Vibraye,* with very large pink fls., with entire sepals. R.B. 37:377. *Président Viger,* very floriferous, clusters large, fls. very large, with dentate sepals, bright pink. *Saarbrücken,* dwarf, with very large heads of pink fls.; sepals denticulate. M.D.G. 1910:601. G.W. 15, p. 76. For other varieties see: M.D.G. 1911:38–41, 265–273; 1912:210, 211.

1931. Hydrangea paniculata var. præcox. (×⅙)

(3) Stellata group: fls. with many narrow sepals.

Var. **stellàta,** Dipp. (*H. stellàta,* Sieb. & Zucc.). Lvs. ovate or ovate-oblong, sparingly pubescent: cymes with larger sterile and smaller fertile fls., both with many narrow-elliptic sepals. S.Z. 59. Var. **fimbriàta,** Dipp. Cymes rather dense, with almost all the fls. sterile; sepals fimbriate, white, pink toward the base. G.C. III. 23, suppl. May 28. Var. **prolífera,** Hort. (*H. stellàta* var. *prolifera,* Regel). The fertile fls. bearing 1 or few smaller ones in the center. Var. **rùbro-plèna,** Dipp. Cymes rather dense, with almost all fls. sterile, changing from pink or pale lilac to dark red.

There are also some varieties with variegated lvs., as var. **variegàta,** Hort. (*H. japónica variegàta,* Hort.), a form of var. *japonica* with the lvs. edged white (H.F. 1861:108); var. **álbo-variegàta,** Hort. (*H. japónica fol. álbo-variegàtis,* Hort.), a form of var. *Belzonii,* with the lvs. edged white (F.S. 7:696. G. 27:517); var. **trícolor,** Hort., with the lvs. variegated with white and edged yellow; var. **ròseo-marginàta,** Hort., with the lvs. spotted white and edged pink; var. **nivàlis,** Hort. (*H. Horténsia nivàlis,* Bull & Sons). Lvs. with a deep green margin and an irregular patch of creamy white in the center. G.C. III. 32:455. G.M. 47:639.



1932. Hydrangea Bretschneideri. (×⅓)

cc. *Ovary inferior, hence caps. truncate, with the calyx-teeth at the apex; styles usually 2.*

d. *Cymes without involucre at the base.*

e. *Branchlets and lvs. glabrous or lvs. villous or tomentose below: seeds not winged.*

f. *Lvs. glabrous below.*

8. **arboréscens,** Linn. (*H. urticifòlia,* Hort.). Erect shrub, 4–10 ft.: lvs. long-petioled, ovate, acute or acuminate, rounded or cordate at the base, serrate, green and glabrous on both sides or somewhat pubescent or glaucous beneath, 3–6 in. long: cymes 2–5 in. broad, with none or few sterile fls. June, July. N. J. to Iowa, south to Fla. and Mo. B.M. 437. G.W. 15, p. 612. Var. **cordàta,** Torr. & Gray, has the lvs. broadly ovate and cordate. Var. **stérilis,** Torr. & Gray. A form with all the fls. sterile; sepals broadly oval, rounded or mucronate at the apex: lvs. oval to oblong-ovate, rounded or abruptly contracted at the base. It is doubtful whether this form is still in cult. Var. **grandiflòra,** Rehd. A form of var. *cordata* with all the fls. sterile: heads 5–7 in. across; fls. ¾–1 in. across with ovate acute sepals: lvs. ovate to ovate-elliptic, cordate or rounded at the base. M.D.G. 1907:380; 1909:4; 1912:472. Gn. 75, p. 435. G.W. 13, p. 617. R.B. 33:375; 34:259. G. 31:671. F.E. 22:70; 28:359; 31:606. G.M. 50:357.—A striking plant with its showy large heads of white fls.; quite hardy.

ff. *Lvs. tomentose or densely grayish pubescent below.*

9. **cinèrea,** Small. Shrub, to 6 ft.: lvs. membranous, oval or broadly ovate to ovate-oblong, rounded or cordate at the base, serrate, densely grayish pubescent below, 2½–6 in. long: corymbs 2–5 in. across, usually with sterile fls. June, July. B.B. 2:185 (as *H. radiata*); (ed. 2) 2:231. N. C. to Tenn. and Ala. Var. **stérilis,** Rehd. All fls. sterile, in dense heads 5–7 in. across; fls. about ½in. across with oval obtuse sepals. F.E. 28:359; 30:911.

10. **radiàta,** Walt. (*H. nívea,* Michx.). Similar to the former, but lvs. leathery, densely whitish tomentose and reticulate beneath and cymes always with sterile fls. June, July. N. C. and S. C. F.E. 32:11.

ee. *Branchlets strigose or bristly and lvs. strigose or densely clothed with rough hairs: seed winged.*

f. *Base of lvs. rounded or subcordate.*

11. **Sargentiàna,** Rehd. Shrub, to 6 ft. with stout upright branches clothed with harsh hairs and stiff bristles: young growth more or less purple: lvs. ovate to ovate-oblong, shortly acuminate, crenate-serrate, dull green and hairy above, densely rough-villous below, 6–12 in. long; petioles 1½–3½ in. long: cymes nearly flat, dense, 5–6½ in. across; fertile fls. pale violet, the sterile fls. white; style 2–3. July, Aug. Cent. China. B.M. 8447. Gn. 77, p. 264. G.M. 55: suppl. p. 5, June 1.—A strikingly handsome plant with its large lvs., the dense pubescence purplish on the young growth and with its large cymes bluish violet in the center and surrounded by conspicuous white sterile fls. It is rather tender and can be grown outdoors in the S. only and demands a shady position.

12. **Rósthornii,** Diels. Shrub, to 12 ft.: branchlets strigose: lvs. roundish-ovate or ovate, occasionally ovate-oblong, acuminate, cordate at the base, unequally or doubly fimbriate-dentate, sparingly strigose above, densely grayish strigose and reticulate below, 4–9 in. long and 3–7 in. broad; petiole 1½–4 in. long: cymes 4–7 in. across; sterile fls. 1–1½ in. across, white or purplish; sepals suborbicular or oval, entire or serrate; styles 2. July. W. China.

ff. *Base of lvs. cuneate.*

13. **strigòsa,** Rehd. (*H. áspera,* Hemsl., not Don). Shrub, to 8 ft.: branchlets strigose: lvs. oblong-ovate to elliptic-lanceolate or lanceolate, acuminate, serrulate or serrate, sparingly strigose or nearly glabrous above, densely strigose below, 3–7 in. long; petiole about 1 in. long: cymes 4–6 in. across; sterile fls. white or sometimes purple, 1–1½ in. across, with broadly oval, entire or serrate sepals; styles 2. Aug. Cent. China. Var. **macrophýlla,** Rehd. (*H. áspera* var. *macrophýlla,* Hemsl.). Lvs. 8–12 in. long: cymes to 8 in. across with the sterile fls. about 2 in. broad.

dd. *Cyme inclosed before expanding by 6–8 large, deciduous bracts.*

14. **involucràta,** Sieb. Low shrub, to 5 ft.: lvs. oblong, acuminate, densely and sharply serrate, appressed-pubescent on both sides, rough to the touch,

4–8 in. long: bracts at the base of the cyme large, orbicular; smaller bracts none: fertile fls. blue or pinkish, sterile ones whitish: caps. with the calyx at the apex; styles usually 2. Aug. Japan. S.Z. 63. J.H. III. 32:102. *H. Sapphire*, intro. 1890, seems to belong here. Var. **horténsis**, Maxim. Fls. double, usually pink and often proliferous. S.Z. 64. F.S. 3:187.

AA. *Shrubs climbing by aërial rootlets: petals cap-like, cohering, falling off as a whole.*

15. **petiolàris**, Sieb. & Zucc. (*H. scándens*, Maxim., not DC. *H. volùbilis*, Hort.). Climbing to 80 ft. in Japan: lvs. long-petioled, broadly ovate-cordate to elliptic, acute or acuminate, serrate, almost glabrous, 2–4 in. long: cymes rather loose, 8–10 in. across, with rather few sterile fls.; stamens 15; styles usually 2: caps. with the calyx at the apex. July. Japan, Saghalin. B.M. 6788. S.Z. 54, 59, 2, 92. M.D.G. 1897:236, 237. S.H. 2:191, 193. Gn. 62, p. 248; 64, p. 219. G. 35:461. —A very variable species, figured and described by Sieb. & Zucc. under 3 different names. In gardens it is often met with under the name of *Schizophragma hydrangeoides*, another Japanese climber of similar habit, which, however, is easily distinguished by its sinuately dentate lvs. and its sterile fls. having only 1 large cordate sepal.

16. **anómala**, Don (*H. altíssima*, Wall.). High-climbing, glabrous: lvs. ovate to elliptic-ovate or ovate-oblong, broadly cuneate at the base, denticulate-serrate, 2–4 in. long; petioles ¾–2 in. long: cymes loose, puberulous, 4–6 in. across; stamens 10; sterile fls. few or sometimes wanting, about 1 in. across, with suborbicular sepals. July. W. China, Himalayas. Wallich, Tent. Flor. Nepal. 50.

H. áspera, Don. Shrub, to 20 ft., similar to H. strigosa: lvs. oblong-lanceolate, fimbriate-denticulate, densely villous beneath: sepals usually toothed: styles usually 3. Himalayas. Tender.—*H. canéscens*, Koch (H. arborescens × H. radiata). Very similar to H. cinerea, but the hairs smooth or nearly smooth under the microscope, in H. cinerea tuberculate. Garden origin.—*H. hírta*, Sieb. & Zucc. Shrub, to 4 ft.: lvs. broad-elliptic, coarsely incised-serrate: cymes without sterile fls. Japan. S. Z. 62. Not very decorative.—*H. lóngipes*, Franch. Allied to H. Rosthornii. Lvs. thinner, smaller, more coarsely serrate, sparingly strigose or glabrescent below; petioles 2–7 in. long. Cent. and W. China.—*H. robústa*, Hook. f. & Thoms. (H. cyanema, Nutt.). Closely related to H. Rosthornii. Spreading shrub, to 15 ft., with large ovate lvs., pubescent on both sides: sterile fls. with toothed sepals. Himalayas. B. M. 5038. Handsome in bloom, but tender.—*H. ròseo-paniculàta*, Foucard. Supposed to be a hybrid of H. paniculata and H. opuloides. Fls. rose-carmine. R. H. 1912, p. 324.—*H. villòsa*, Rehd. Allied to H. strigosa. Branchlets, petioles and cymes clothed with spreading villous hairs: lvs. strigose above, with a rough woolly tomentum below, 4–7 in. long. W. China. Var. *strigòsior*, Rehd. Branchlets and petioles with shorter and fewer or without spreading hairs: lvs. smaller.—*H. virens*, Sieb. Slender shrub, to 6 ft.: lvs. elliptic or lanceolate, coarsely serrate, 1–2½ in.: cymes rather few-fld., sterile fls. with 3 or 4 large, unequal sepals, white. Japan. S. Z. 60. A desirable shrub, with graceful and delicate fls. and with the lvs. often handsomely variegated along the veins, but tender.

ALFRED REHDER.

HYDRÁSTIS (name of doubtful meaning). *Ranunculàceæ.* Hardy herbaceous perennials, grown in a few gardens for their showy leaves and beautiful red fruit. The roots are ground when dry and used for medicine.

Stem erect, pubescent: lvs. palmately 5–7-lobed, serrate: fls. greenish white, small, solitary; sepals 3, petal-like, falling early; petals none; stamens many: carpels 2-ovuled, in fr. becoming aggregated berries. —Two species, 1 from Japan and 1 from N. Amer., the former (*H. jezoensis*, Sieb.) apparently not in cult.

Moist situations in good, rich loam with plenty of leaf-mold are required. Seeds may be sown in moist, shaded soil of a sandy nature. This is done in fall or early spring. The seeds should be covered very slightly but a mulch or covering is helpful. Plants which have grown in one place for a number of years are easily propagated by division of the roots in late fall or early spring. The commercial cultivation of goldenseal for medicinal purposes is explained in Farmers' Bulletin No. 613 (United States Department of Agriculture) by Walter Van Fleet.

canadénsis, Linn. ORANGE ROOT. GOLDENSEAL. St. 4–10 in. long, from a thick, yellow rootstock: basal lvs. 5–8 in. broad; st.-lvs. 2, lower one petioled, upper sessile and near the small fl.: fr. in ovoid raspberry-like head, the 8–12 fleshy carpels tipped with a short, curved beak. April. E. U. S., as far south as Mo. and Ga., in rich woods. B.M. 3019 (in flower); 3232 (in fruit).

K. C. DAVIS.

HYDRIASTÈLE (Greek, *water* and *column;* the tall trunks growing near springs). *Palmàceæ*, tribe *Arèceæ.* A monotypic genus containing a tropical Australian palm advertised sometimes as *Kentia Wendlandiana.* This may belong to Exorrhiza, which see. If it is a true Hydriastele, however, it is told from the kentias in foliage by the leaf-segments split at the apex instead of acuminate and not split.

1933. Hydrangea hortensis var. otaksa.

More fundamentally, Hydriastele differs in having the ovule on the side of the cell instead of at the bottom, as in Kentia. In this respect it agrees with the group of genera mentioned under Hedyscepe, but it differs from that group in having the fls. borne in 4 ranks instead of spirally. Hydriastele is a spineless palm with erect winged caudex: lvs. terminal, pinnatisect; segms. alternate, linear, split at the apex; midveins covered below with caducous scales; margins thin; rachis laterally compressed, dorsally convex; face of the petiole concave; sheath rather short: spadices with short, wide peduncles, branched from the base, the branches obtusely quadrate, long, slender, pendulous: spathes 2, complete, compressed, deciduous, the lower one ancipital: bracts and bractlets connate: fr. small, ellipsoidal, smooth or ribbed.

This distinct and excellent palm has hitherto been rare, but now that the seeds are being produced in tropical nurseries it is fast becoming popular. The seeds are round, fairly hard, and resemble those of *Archontophœnix Alexandræ.* The characteristic leaves are pinnatifid, the segments being irregular and somewhat jagged at the apex, after the fashion of a fish-tail palm or caryota. It stands the temperature of an ordinary living-room better than many other palms. For rapid growth it needs more heat than *Howea Belmoreana* and *H. Forsteriana.* In the greenhouse a temperature of 60° to 70° is most congenial. A lower temperature will not hurt it, but gives a slower and more compact growth. It loves plenty of moisture, and frequent syringing is beneficial. For potting soil, it likes rich loam, with plenty of sharp sand and good drainage. The seeds and seedlings should be treated more like the commercial areca, i.e., *Chrysalidocarpus lutescens*. It forms a single stem when only 3 feet high, and grows to a height of 20 feet or more in cultivation. It is at its best when 10 to 15 feet high. When well established and pot-bound it loves high feeding, as does *Chrysalidocarpus lutescens*. (H. A. Siebrecht.)

Wendlandiàna, H. Wendl. & Drude (*Kéntia Wendlandiàna*, F. Muell.). A tall palm in nature with the lvs. many feet long; segms. numerous, unequal, the longest 1½ ft., the upper ones confluent at the base, all denticulate at the apex. Queensland.

N. Taylor.†

1934. Hydrocleis nymphoides. (×⅔)

HYDRÍLLA (*water* plant with *whorled* lvs.). *Hydrocharitàceæ*. One aquatic plant of Cent. Eu., Asia and Austral., offered abroad as a water or aquarium subject. **H. verticillàta,** Casp. Forming large masses, leafy, submerged, diœcious: lvs. linear or oblong, serrulate or entire, 4–8 in a whorl, very short (¼–⅓in. long): sterile or male fls. solitary and short-pedicelled in a sessile spathe; sepals, petals and stamens 3: fertile or female fls. 1–2 and sessile in the spathe; sepals and petals 3; ovary extending beyond the spathe into a beak; stigmas 3: fls. very small; the male fls. detach and float.

L. H. B.

HYDRÓCHARIS (Greek, *graceful water plant*). *Hydrocharitàceæ*. Frogbit. A monotypic genus, an aquatic plant, grown in a few aquaria. It is found in ditches and ponds in Eu. and Temp. Asia. **H. Mórsus-rànæ,** Linn., has floating sts. resembling runners, and tufts of radical lvs. and submerged roots: lvs. stalked, roundish, with a heart-shaped base, rather thick, about 2 in. across: peduncles of the staminate plant bearing 2–3 fls. on long pedicels, which spring from a spathe of 2 thin bracts; petals 3, white, stamens 3–12; spathe of the pistillate fls. sessile among the lvs.; styles 6, with 2-cleft stigmas. For American frogbit, see *Limnobium*. Hydrocharis dies in the fall, but winter-buds (see similar buds of Elodea, Fig. 1391) break off and sink when the old plants die. In spring, or in the greenhouse or aquarium under genial conditions, they start early into growth, the scales bursting and a young lf. developing and then the whole rises to the surface. It is a very interesting plant. Its fine, silky roots are beautiful and attractive in the aquarium, as well as the soft, tender lvs. and delicate fls.

Wm. Tricker.

HYDRÓCLEIS (*water key*). *Butomàceæ*. Sometimes spelled *Hydrocleys*. Water plants, one of which is very useful for summer ponds and for aquaria.

Floating: lvs. broad, ovate to strap-shaped: fls. perfect, mostly large; sepals 3, coriaceous and persistent; petals 3, thin and fugacious; stamens many or numerous, the external sterile: carpels 3, rarely 4 or 6 or even 8, lance-linear, connate at base, gradually attenuate into the style.—The latest monograph (Buchenau, Engler's Pflanzenreich, hft. 16, 1903) recognizes 3 species, from Brazil. The genus is sometimes united with Limnocharis, from which it differs in having definite rather than many carpels, and the papillose introrse stigmas.

nymphoìdes, Buchen. (*H. Cómmersonii*, Rich. *H. Húmboldtii*, Endl. *Limnócharis Húmboldtii*, Rich. *L. Cómmersonii*, Spreng. *L. nymphoìdes*, Mich. *Stratiòtes nymphoìdes*, Willd. *Vespúccia Húmboldtii*, Parl.). Water-Poppy. Fig. 1934. Perennial: st. prostrate and rooting: lvs. broad-cordate-oval, thick, mostly floating: fls. and lvs. arising from bracted nodes, both long-stalked: fls. 2–2½ in. across, with 3 obovate-rounded light yellow petals: carpels 5–7, not united. Brazil, to Buenos Ayres. B.M. 3248. B.R. 1640.—A handsome plant with the yellow fls. (lasting 1 day) standing well above the water. In habit, remarkably like *Limnanthemum nymphoides*. Grows well in an aquarium or in shallow water. Continuous bloomer; not hardy to frost. The cult. of *Hydrocleis nymphoides* is of the simplest. When grown in tubs, fill them in two-thirds full of moderately rich soil, covering with sand and fill up with water. Two or 3 plants planted in the center in a short time will furnish the tub with its bright glossy green lvs. and numbers of its bright cheery yellow fls., which continue late in the season. In natural ponds, planted on the edge, the plants grow very rapidly, and spread over a large surface of water. In artificial ponds, plant in tubs or boxes and place in shallow water or stand the tub or box on some stand, allowing 6–9 in. depth of water.

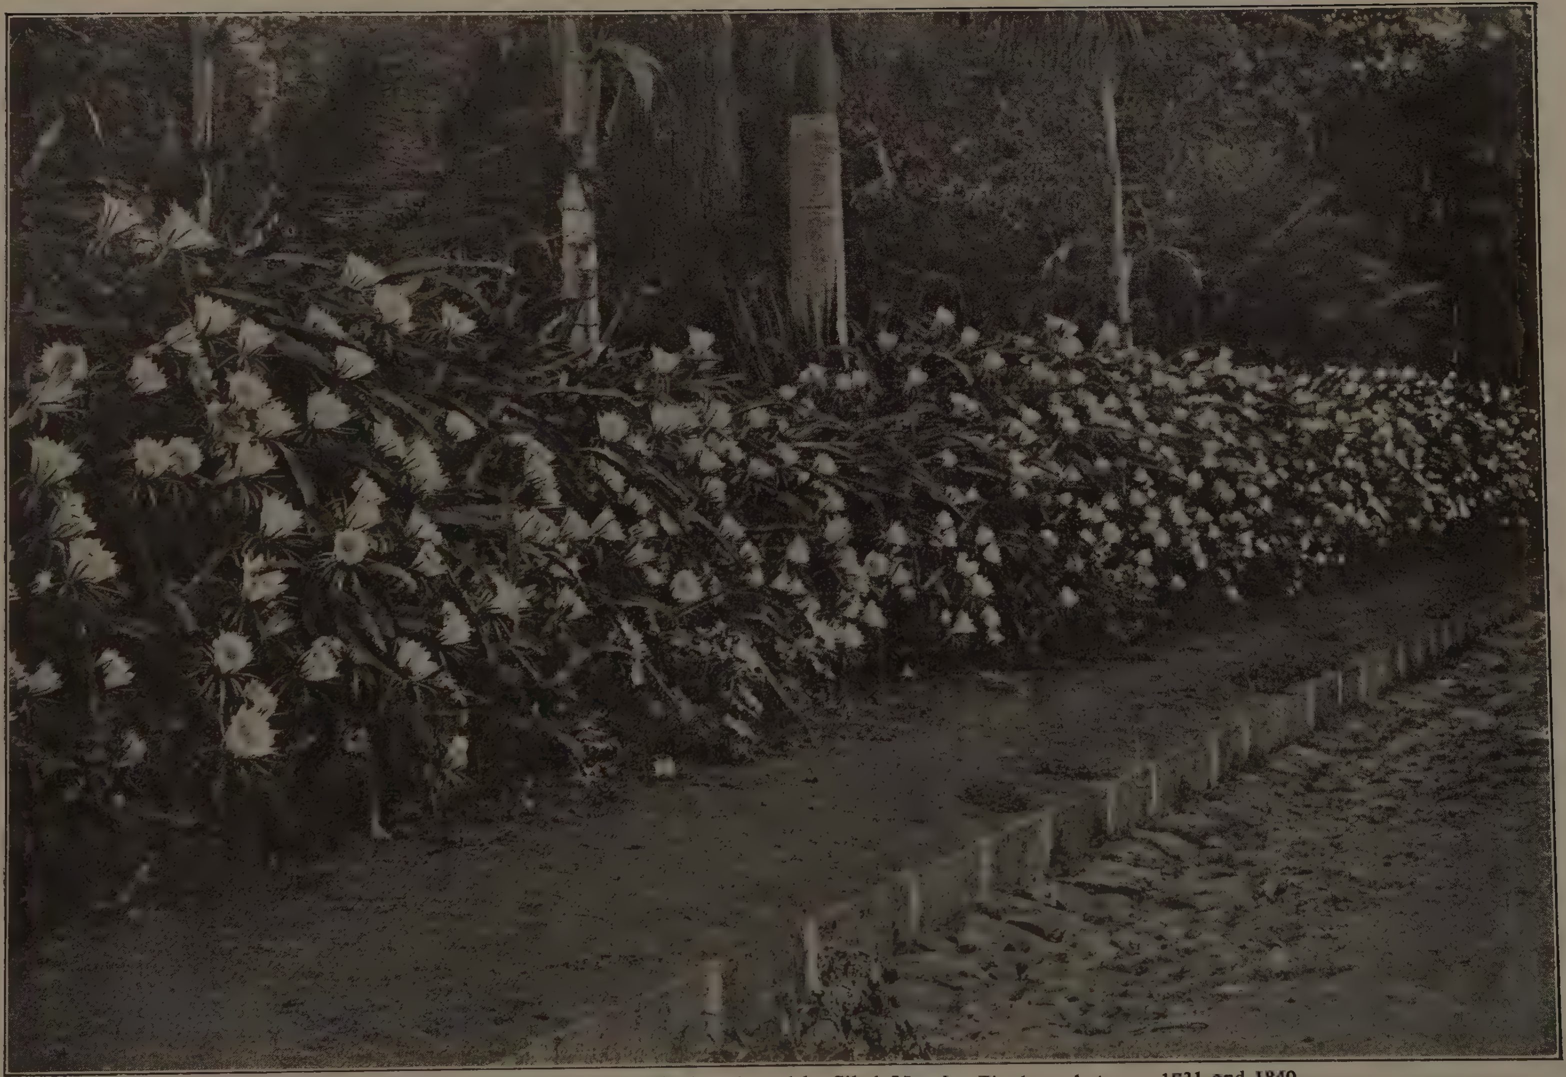
William Tricker.
L. H. B.

HYDROCÓTYLE (Greek, *water* and *cup;* the plants thrive in moist places, and the roundish leaves have a cup-like depression in the middle). *Umbelliferæ*. Water Pennywort. Slender creeping perennials of wet places, one of which is somewhat used in carpet-bedding.

Herbs, with round or reniform often peltate lvs., and scale-like stipules at the base of the petioles: fls. very small, white, in umbels or umbel-like clusters opposite the lvs., sometimes 1 umbel appearing above another; calyx-teeth minute; petals entire, concave: fr. strongly compressed.—Species about 75, widely distributed around the world, several being native in the U. S. and Canada.

1935. Hydrocotyle rotundifolia. (×⅓)

rotundifòlia, Roxbg. (*H. sibthorpioìdes*, Lem. *Sibthórpia europæa*, Hort., not Linn.). Fig. 1935. Lvs.



LVII. Hylocereus tricostatus in Hawaii. Hedge planted by Sibyl Moseley Bingham, between 1831 and 1840.

shining, ¼–1 in. across, orbicular, cordate, subentire or 7–9-lobed to the middle or lower, doubly crenate: umbel 6–8-fld.: fr. 2-ribbed. Trop. Asia and Afr.—Numerous synonyms are accounted for by the variable length of the petiole. Prostrate, rooting at the nodes.

vulgàris, Linn., offered abroad: creeping or floating, rooting at the nodes: lvs. orbicular, 1 in. or less across, crenate or slightly lobed, centrally attached, the petioles surpassing the peduncles: fls. minute, white, in 2 or 3 whorls or in a single umbel: marshes and bogs, and edges of ponds. Eu. L. H. B.†

HYDRÒLEA (probably from *water*, because of the habitat). *Hydrophyllàceæ.* Annual or perennial herbs or subshrubs, scarcely cult., of warm countries and a few in the U. S.; species perhaps a dozen: now often included with Nama (which see): branching plants, sometimes spiny: lvs. ovate or lanceolate, entire, pinnate-veined: fls. blue or white, in clusters or solitary; corolla broadly campanulate or nearly rotate, 5-cleft; stamens 5, about the length of the corolla, with filaments dilated below: fr. a globular caps. with minute seeds. Four species occur in the U. S.: *H. corymbòsa,* Ell. (*Nàma corymbòsum,* Kuntze), with clustered blue yellow-nerved fls. ⅔in. across, and oblong to oblanceolate lvs.: S. C. to Fla. *H. quadriválvis,* Walt. (*H. caroliniàna,* Michx. *Nama quadriválvis,* Kuntze), with solitary or few-clustered blue or lilac fls., and linear-elliptic lvs.: Va., south. *H. ovàta,* Nutt. (*Nama ovàtum,* Brit.), with purplish or white fls. in leafy-bracted panicles, and ovate or elliptic lvs. Swamps, Mo. to La. and Texas. *H. affinis,* Gray (*Nama affine,* Kuntze), with violet fls. in few-fld. leafy clusters, and linear-elliptic lvs. Ind. and Ill. to Miss. and Texas. L. H. B.

HYDROPHÝLLUM (Greek, *water-leaf; application* obscure). *Hydrophyllàceæ.* WATER-LEAF. A half-dozen or more American hardy herbaceous plants, mostly perennial, suitable for wild gardens and for colonizing in shady rich places.

Plants with pinnate or palmately cut foliage and cymose clusters of numerous small white, lilac, light blue, purplish or violet fls. in early summer: floral parts in 5's; calyx appendaged or not; corolla bell-shaped, the tube within bearing a linear longitudinal appendage opposite each lobe, with infolded edges, forming a nectar-bearing groove; stamens and 2 styles usually exserted: caps. 2-valved, with 1–4 nearly globular seeds.—Mostly in moist woods and copses. The perennial species are useful for planting about remote borders of shrubbery, where they take care of themselves.

A. *Calyx appendaged with a reflexed lobe at each sinus: biennial.*

appendiculàtum, Michx. Loosely branching, 1–2 ft., hirsute with long spreading hairs: root-lvs. pinnately 5–7-parted; st.-lvs. palmately 5–7-angulated-lobed: fls. violet or purple, the stamens little exserted. Vt., south and west.

AA. *Calyx not prominently appendaged (often minutely appendaged in H. canadense): perennial.*

B. *Lvs. pinnately cut.*

capitàtum, Douglas. Tufted, about 9 in. high, with fascicled fleshy roots: lvs. softly hirsute or pubescent, ovate or roundish, 5–7-parted, the divisions lobed and cleft: fls. in close clusters, on peduncle shorter than petiole, blue. Colo., west.

occidentàle, Gray. Pubescent, hirsute or sparingly hispid, 1–2 ft.: divisions of the lf. 7–15: fls. violet-purple, varying to white; peduncle longer than the petioles. Calif., Ore.

virginiànum, Linn. Glabrous or nearly so, 1–2½ ft.: lvs. pinnately divided, the 5–7 divisions ovate-lanceolate or oblong: fls. white or violet-purple, the peduncles longer than the petioles. Quebec, west and south.

BB. *Lvs. palmately cut.*

canadénse, Linn. Nearly smooth, 1–2½ ft.: lvs. 5–7-lobed, rounded: fls. mostly greenish white, sometimes purplish the peduncles usually shorter than petioles. B.R. 242. L. H. B.

HYDRÓSME (name probably refers to the wet or aquatic habitat). *Aràceæ.* By some held to be the proper genus for *Amorphophallus Rivieri* (*H. Rivieri,* Engl.); but in the latest monograph (Engler, Pflanzenreich, hft. 48, 1911) it is included in Amorphophallus, as is also Corynophallus, constituting a section of the genus. When kept distinct from Amorphophallus, the separation is largely on technical characters of the seeds.

The section Corynophallus of the genus Amorphophallus, as accepted by Engler, comprises only *Amorphophallus leonensis,* Lem. (*Corynophallus Afzelii,* Hort. *C. leonensis,* Engl. *Hydrosme leonensis,* Engl.), which is sometimes cult. in two or three forms (Vol. I, p. 276): peduncle very stout, 3–8 in. high, from an oblate tuber, bearing a pyriform erect spathe 6 in. high; tube of spathe 1¾ in. diam, white; limb concave, 3½ in. broad at about the middle, rounded at top; mouth of spathe dark purple streaked with dirty white and bearing a few roundish spots; lips of spathe black-purple, incurved: spadix expanding toward the top so that it nearly fills the spathe, brown and mottled: lf. 1, appearing after the fls., on an erect petiole 2–3 ft. high, the blade about 12 in. across and trisect; primary segms. 1- or 2-pinnatifid, the ultimate segms. narrow-linear. Sierra Leone, and adjacent regions. B.M. 7768. F.S. 2:161. G.C. 1872:1619. Var. *spectábilis,* N.E. Br. (*Corynophállus Afzèlii* var. *spectábilis,* Mast.), petiole bearing obscure linear-oblong spots. Var. *élegans,* N. E. Br. (*C. Afzèlii* var. *élegans,* Mast.), petiole green, segms. 2-pinnatisect, the ultimate segms. very narrow. Var. *latifòlia,* N. E. Br. (*C. Afzèlii* var. *latifòlia,* Mast.), petiole green, segms. pinnatisect, the ultimate segms. broader and confluent.—This variable species may be found only rarely in choice collections. L. H. B.

HYDROTÆNIA (Greek, *water* and *band;* referring to a triangular glandular bar which secretes nectar). *Iridàceæ.* Four species of tender bulbs from Mexico and Peru, more curious than beautiful, allied to Tigridia.

From Tigridia (with which the genus is sometimes united), it is distinguished by the perianth-segms. lacking a spreading blade, the perianth being campanulate; tube none; filaments united in a cylindrical column as long as the anthers; ovary clavate, 3-celled: sts. 1–3 ft., simple, or slightly branched above, bearing 1 or more lvs.: cormous.

Van Hoùttei, Baker. St. 2–3 ft. long, bearing 2–3 fls.: lvs. lanceolate, plaited, the lower 1 ft. long: spathes inflated, 2 in. long: outer segms. oblong, over 1 in. long, greenish outside, inside dark brown, much veined, yellowish at tip, very obtuse: inner segms. suborbicular, half as long, pale lilac, somewhat veined. Mex. F.S. 21:2174 (as *Tigridia Van Houttei*).—Corm said to be eaten in its native region. L. H. B.

HYLOCÈREUS (*wood* and *Cereus*). *Cactàceæ.* A high-climbing cactus, with stems three-angled or -winged, adhering to walls and trees by numerous aërial roots.

Spines small, usually inconspicuous: fls. nocturnal, usually very large, with red or greenish sepals, white or pinkish petals: fr. large, spineless, covered with numerous lf.-like bracts.—Some 16 species of this genus are known, but only 1, and that under a wrong name, is grown to any extent in this country. The species are easily grown in hothouses, especially if given a wall to climb upon. A very curious small-fld. species, *H.*

minutiflorus, has recently been described by Britton & Rose. It flowers freely in Washington and New York, but as yet has not been very widely distributed.

tricostàtus, Brit. & Rose (*Cèreus tricostàtus*, Gosselin. *C. triangulàris* of most writers, not of Haw.). Plate LVII. Vines often 20–40 ft. long, green: ribs 3, thin, crenate, with a corneous margin: spines 2–4 from each areole, short: fls. about 1 ft. long, white: fr. large, red without, white within, edible. Mex. B.M. 1884.

H. exténsus, Brit. & Rose (Cereus extensus, Salm-Dyck). Sts. creeping, perhaps also sometimes climbing, bearing aërial roots, green, rather slender, 3-sided, with obtuse angles: fls. large and handsome; sepals tipped and margined with red; petals rose-colored; style thick, longer than the stamens. This species was described by De Candolle in 1828, but it is unknown in cult. and in a wild state. A species under this name was figured in B. M. for 1844, but this may or may not be the plant described by De Candolle.—*H. napoleònis*, Brit. & Rose (Cereus napoleonis, Graham). Sts. much branched, with 3 acute angles; spines 4–5, rigid, 4–5 lines long: fls. 8 in. long; sepals yellow; petals pure white. This species is not in cult. and is not known in the wild state. It was described and figured from a plant which flowered in Edinburgh about 1836. It is occasionally reported in cult.; but all such material seems to be wrongly identified.

J. N. Rose.

HYMENÆA (Greek, *nuptial;* in allusion to the paired lfts.). *Leguminòsæ.* Ten species of evergreen unarmed trees in Trop. Amer.: lvs. alternate, with 1 pair of coriaceous lfts.: fls. in short corymbose panicles; sepals 4; petals 5, generally oblong, scarcely longer than sepals; stamens 10, distinct; ovary short-stalked with few seeds: pod oblong to obovate, thick, often nearly cylindric, woody, indehiscent. The following species is the most important of the genus and occasionally cult. in tropical collections and in greenhouses of botanic gardens for its economic interest. Prop. is by cuttings in summer under glass with bottom heat or by seeds. It yields a fragrant amber-like resin known as courbaril, or American or West Indian copal; the heavy, close-grained and hard wood is used for wheelwork, tree-nails, beams and in various machinery; the sweetish acid pulp of the pods is eaten by the Indians.

Courbaríl, Linn. Tree, to 60 ft.: lfts. 2, nearly sessile, oblong, very oblique at the base, acuminate, glabrous, about 3 in. long; petiole ½in. long: fls. short-pedicellate; petals about ¾in. long, yellow, striped purplish: pod few-seeded, 3–4 in. long. W. Indies to Brazil.

Alfred Rehder.

HYMENÁNTHERA (from the Greek for *membrane* and *anther*, in allusion to the anthers being terminated by a membrane). Syn. *Solenántha. Violàceæ.* Stiff shrubs or small trees: lvs. alternate or sometimes fascicled, entire or toothed, with small fugacious stipules: fls. small, axillary or on the naked branches below the lvs., regular, hermaphrodite or unisexual: fr. a small subglobose berry; seeds 2, rarely 3–4.—About half a dozen species from New Zeal., Austral., Tasmania and Norfolk Isls. *H. crassifòlia*, Hook. f., is offered abroad. A low, rigid, much-branched shrub 2–4 ft. high: bark white, furrowed: lvs. very thick and coriaceous, linear-spathulate, entire, sinuate or toothed: fls. small, solitary or few together, axillary: berry white or purplish, ⅙–¼in. diam. New Zeal. Gn. 75, p. 568.—A variable species. Should be grown in a warm, sunny place as a rock-garden plant. Prop. by seeds, cuttings or layers in summer. Good for amateurs on account of the early fls., March to April, and particularly the ornamental berries, which retain their characters a long time. In cold climates needs winter protecton; hardy in south of England.

L. H. B.

HYMENOCÁLLIS (*beautiful membrane*, alluding to the webbed filaments). Including *Ismène. Amaryllidàceæ.* Spider-Lily. Sea-Daffodil. Bulbous plants of the warm parts of the New World (one in Africa), cultivated for the fragrant white (in one species yellow) umbellate flowers.

Perianth salverform, with a cylindrical tube, equal linear or lanceolate segms.; stamens 6, the filaments free above but webbed and united into a cup below, the anthers narrow and versatile; ovary 3-loculed, with 2 collateral ovules in each, bearing a long slender style and very small capitate stigma: scape solid and compressed, arising from a tunicated bulb: lvs. oblong or strap-shape.—Species about 40, from N. C. and Mo. to S. Amer., 1 from W. Afr. The genus is represented in the Old World by Pancratium, which differs chiefly in having many superposed ovules in each locule.

Some of the species of Hymenocallis are winter bloomers: these should be treated essentially like crinums, being rested or kept slow in the summer. They require a warm temperature. Of such are *H. macrostephana*, *H. speciosa*, *H. caribæa.* Other species require an intermediate or conservatory temperature, and bloom in spring or summer, resting in winter. Of such are *H. calathina*, *H. Harrisiana*, *H. Macleana*, *H. rotata*, *H. littoralis.* Some of these latter or intermediate-house species are hardy in the southern states, there blooming in spring, as *H. lacera*, *H. galvestonensis*, and others. The species of hymenocallis require no special treatment (see *Bulb*), except that the same bulbs may be flowered year after year if they receive good care. Use turfy or peaty soil that will not become "sour" or soggy. Propagation is by offsets from the bulbs. See *Amaryllis*, for the general handling of this class of bulbs.

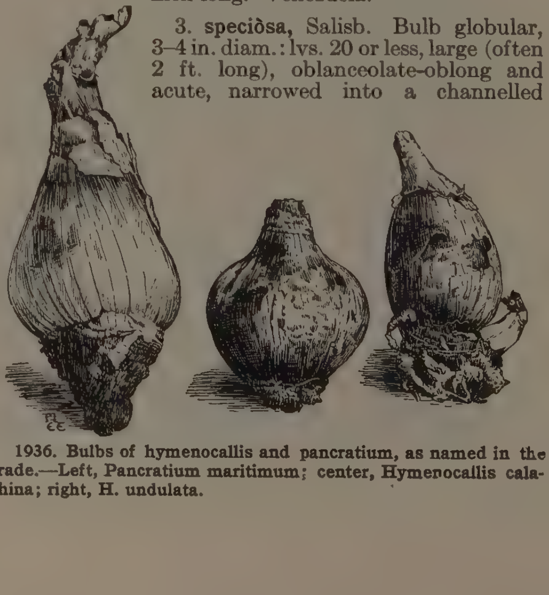
A. *Filaments long and slender beyond the small cup.*

B *Lvs. distinctly petioled.*

1. **tubiflòra**, Salisb. Bulb ovoid, about 4 in. diam., short-necked: lf.-blade about a foot long and one-third to one-half as broad at the middle, the petiole 6–12 in. long: scape 1 ft. tall; fls. many in the umbel and sessile, the valves or bracts broad and cuspidate; tube of perianth greenish, 6–8 in. long, the linear white reflexing segms. 4 in. long; cup 1 in. long, not toothed, less than half or a third the length of the free part of the filament. N. E. S. Amer. B.R. 265 (as *Pancratium guianense*, Ker).

2. **undulàta**, Herb. Fig. 1936. Bulb ovoid, 3–4 in. diam.: lvs. with an oblong blade 1 ft. long and half as wide, cross-veined: scape 2 ft. long, compressed; fls. about 10, sessile, the tube 6–7 in. long, and the segms. 3–4 in. long and linear, white, with tinged red cup an inch long. Venezuela.

3. **speciòsa**, Salisb. Bulb globular, 3–4 in. diam.: lvs. 20 or less, large (often 2 ft. long), oblanceolate-oblong and acute, narrowed into a channelled



1936. Bulbs of hymenocallis and pancratium, as named in the trade.—Left, Pancratium maritimum; center, Hymenocallis calathina; right, H. undulata.

petiole: scape mostly shorter than the foliage, glaucous; fls. 10–15, on very short pedicels, the bracts or spathe-valves 3–4 in. long; tube of perianth greenish, 3–4 in. long, the segms. often twice longer (entire fl. often 9 in. long); cup about 1½ in. long, toothed, the free parts of the filaments little longer than the cup. W. Indies. B.M. 1453. Gn. 47, p. 294. F. 1883, p. 71.—One of the best. The bulb improves with age if care is taken in growing and repotting. The lvs. are evergreen and handsome. Fls. very fragrant, and retaining their scent even when dried. Blooms in winter. This and *H. macrostephana* are the most showy species. Var. **angustifòlia,** Worsley, is a very stiff narrow-lvd. form of recent date.

BB. *Lvs. not petioled, strap-shaped.*

C. *Perianth-tube mostly above 3 in. long.*

4. **littoràlis,** Salisb. Bulb 3–4 in. diam.: lvs. about 12, 2–3 ft. long, 1½ in. broad, acute: scape 2-edged, 2 ft. or less tall; fls. 4–8 in a sessile umbel, the tube 6–7 in. long and green-tinged, the segms. linear and recurved, 4 in. long, joined to the base of the cup; the cup funnel-shape, broader and longer, toothed, the free part of the filaments about 2–3 in. long; style about equaling the stamens. Trop. Amer., widely distributed. Gn. 53, p. 57.—Long known in cult., but less showy than other species.

5. **senegámbica,** Kunth & Bouché. Lvs. somewhat curved, acute, 2 ft. long, 2 in. broad at the widest place: scape about as long as the lvs.; fls. 6–8 in a sessile umbel, the tube 5–6 in. long, segms. very narrow and 4 in. long; cup funnel-shaped, 1 in. long and somewhat broader, the free parts of the filaments 2 in. long. W. Afr.

6. **Harrisiàna,** Herb. Bulb globular, small (less than 2 in. diam.): lvs. only 3–6, a foot long and 2 in. broad, much narrowed below: scape less than 1 ft. tall, slender, glaucous; fls. 2–3 in a sessile umbel, the tube slender and 3–4 in. long, the segms. linear and 3 in. or less long; cup funnel-shaped, ¾in. long, plicate, small-toothed, the free filaments 1½ in. long and often exceeding the style. Mex. B.M. 6562.—Flowers in early summer. Hardy S.

CC. *Perianth-tube mostly under 3 in. long.*

7. **caribæ̀a,** Herb. (*Pancràtium caribæ̀um,* Linn. *P. declinàtum,* Jacq.). Bulb globular, 3–4 in. diam.: lvs. thin, 12 or more, not 2-ranked, shining, 2–3 ft. long, 2–3 in. broad at the widest place: scape sharp-angled, nearly or quite as long as the lvs.; umbel sessile, 6–12-fld.; tube 2–3 in. long, the segms. linear and somewhat exceeding it; cup 1 in. long, toothed, the free part of the filaments 1½–2 in. long. W. Indies. B.M. 826. L. B.C. 6:558.

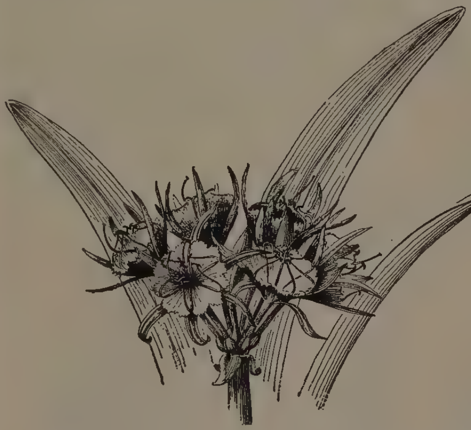
8. **galvestonénsis,** Baker. Scape 1–2 ft. long, rather shorter than the linear lvs.: umbel sessile, 4–6; perianth-tube 2–3 in. long (sometimes shorter), mostly a little shorter than the linear segms.; cup 1¼ in. or less long, funnel-shape, the edge erect, the free part of the filaments little more than ½in. long. Texas.—Intro. to cult. with the statement that it "may be planted out in gardens all over the N. like a peony and prove hardy." Spring or early summer.

9. **rotàta,** Herb. (*H. lácera,* Salisb. *Pancràtium rotàtum,* Ker). Bulb ovoid, 2 in. or less diam., with a long neck and producing stolons or runners: lvs. 6–8, linear, 1½ ft. or less long, flat above but concave toward the base: scape 2-edged, glaucous, about as long as the lvs.; umbel sessile, with 2–6 fls.; tube green, 3–4 in. long, exceeded by the linear, often recurved lobes; cup saucer-shaped or rotate, irregularly toothed, the free part of the filaments 1½ in. long. N. C. to Fla. in low places and in sandy soil. B.M. 827. L.B.C. 1:19.—Variable, particularly in the dimensions of the fl. Spring or early summer.

10. **macrostéphana,** Baker. Fig. 1937. Closely allied to *H. speciosa* and conjectured by Baker to be a hybrid of that species and *H. calathina.* Bulb with a long neck: lvs. 8–9, oblanceolate and bright green, 2–3 ft. long: fls. 6–10, large and striking because of the great cup (whence the specific name), which is 2 in. across and as much long, wavy-toothed; tube greenish, 3 in. long; segms. linear-lanceolate, a little longer than the tube. B.M. 6436.—Blooms in Feb. and March. One of the best of the spider-lilies, perhaps the best for warmhouse cult.

AA. *Filaments short and incurved (usually less than 1 in. long) beyond the large cup. (Ismene.)*

11. **Macleàna,** Nichols. (*Ismène Macleàna,* Herb.). Bulb ovoid, 2 in. diam: lvs. a foot or more long and nearly 2 in. broad, narrowing toward the base: scape 2-edged, about the length of the lvs.; fls. 2–8, with a straight tube 2 in. or less long, and linear, erect or somewhat spreading segms. as long as the tube; cup corolla-like, 1½ in. long and green-striped, fringed, the free filaments ½in. long, strongly inflexed and angled or kneed at the cup. Peru. B.M. 3675.—One of the plants known to the Peruvians as Amancæs, the subject of festivals. This and the next are intermediate house species, flowering in spring and summer.



1937. Hymenocallis macrostephana. (×⅛)

12. **calathìna,** Nichols. (*Ismène calathìna,* Herb. *Pancràtium calathìnum,* Ker). Fig. 1936. BASKET-FLOWER. Bulb long-necked: lvs. 6–8, somewhat 2-ranked, star-shaped, 2 ft. or less long: scape 2-edged, 1½ to 2 ft. tall, bearing 2–5 fls. in a sessile umbel; tube green, 3–4 in. long, much enlarging above; segms. as long as the tube, ½in. wide, lanceolate; cup corolla-like and green-striped, usually larger than in the last, with rounded fringed lobes; filaments, free for ½in., incurved but not angled. Peru, Bolivia. B.M. 2685.—One of the paler kinds.

The following names may be expected in the trade: *H. adnàta,* Herb.=H. littoralis.—*H. Amáncæs,* Nichols., is one of the Ismene group, and the only species with yellow fls. B.M. 1224. B.R. 600. Gn. 48, p. 168.—*H. amæ̀na,* Herb.=H. ovata (below).—*H. Andreàna,* Nichols. An Ismene: fl. only 1, the cup nearly or quite as long as the segms. R.H. 1884, pp. 129, 468.—*H. crassifòlia,* Herb. =H. occidentalis.—*H. Érnstii,* Worsley. Garden hybrid, H. Moritziana being one of the parents.—*H. fràgrans,* Salisb.=H. ovata (below).—*H. Moritziàna,* Kunth. Evergreen, with lvs. like eucharis: fls. white, fragrant, with greenish tubes, very slender and twice as long as the segms., the cup very short and toothed. Venezuela. G.C. III. 27: 89.—*H. occidentàlis,* Kunth. Bulbs large: lvs. evergreen, thick, strap-shaped: fls. white, 3–6, the tube 3–4 in. long; cup much narrowed below. S. C. to Mo. and south.—*H. ovàta,* Roem. Lvs. broad and petioled: fls. 6–10, the tube about 2 in. long, the linear segms. little longer; cup 1 in. long. W. Indies. B.R. 43. B.M. 1467.—*H. schizostéphana,* Worsley. Cup laciniate: fls white, 12–20 in an erect, crowded umbel, the filaments very short and winged at base. Probably Brazil.

L. H. B.

HYMENÒDIUM: *Elaphoglossum.*

HYMENOPHÝLLUM (Greek, *membrane-leaf*). *Hymenophyllàceæ.* Like all members of the family, the species are small and with lvs. of very delicate texture; the sporangia are borne in marginal sori protected by 2-lipped cup-like indusium; otherwise the species are like those of Trichomanes, the other large genus of the family.—A genus of about 240 species, nearly all of which are tropical. Culture p. 1214.

A. *Lvs. glabrous; rachis slightly winged above.*

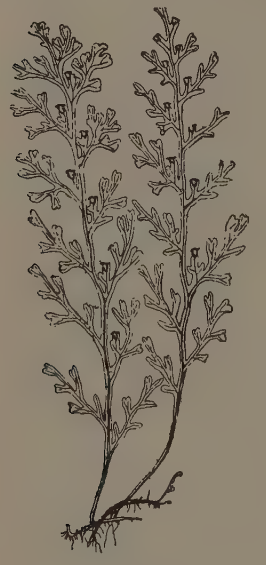
polyánthos, Swartz. Lvs. 2–8 in. long, 1–3 in. wide, tripinnatifid; sori 2–12 to a pinna: involucre small. Tropics of both hemispheres.

demíssum, Swartz. Lvs. 4–12 in. long, 3–4 in. wide, 3–4-pinnatifid; sori very numerous, 20–30 to a pinna: involucre with ovate entire valves. E. Indies to New Zeal.

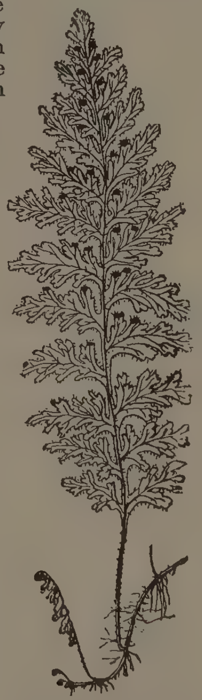
AA. *Lvs. pubescent or ciliate.*

ciliàtum, Swartz. Fig. 1938. Lf.-stalks ciliated and winged above; lf.-blades 2–6 in. long, 1–2 in. wide, tripinnatifid. the segms. ciliated: involucre roundish, the valves divided half way down and ciliated. Tropics of both hemispheres.

æruginòsum, Carm. Fig. 1939. Lf.-stalks tomentose; lf.-blades 2–3 in. long, 1 in. or less wide, tripinnatifid, the pinnæ often imbricate, the surface and margins densely pubescent: involucres small with valves divided nearly to the base, densely ciliate. Tristan d'Acunha.



1938 Hymenophyllum ciliatum. (×½)



1939. Hymenophyllum æruginosum. (Nat. size)

H. dicranótrichum, Sadeb. (H. chiloense, Hook.). A S. American species with triangular lvs. 2–4 in. long, 1 in. broad, bipinnatifid with rounded segms.; the margins and under surfaces hairy. Gn. 74, p. 228.—*H. fucoìdes,* Swartz. A common Trop. American species with oblong lvs., 6–10 in. long, 1½–2 in. broad, tripinnatifid, the rachis and mid-veins of the pinnæ winged, the ultimate segms. linear, spinulose. Gn. 74, p. 228.

L. M. Underwood.
R. C. Benedict.†

HYMENÓSPORUM (Greek, *membrane* and *seed;* referring to the winged seeds). *Pittosporàceæ.* An ornamental evergreen shrub or tree from Australia, cultivated in California for its handsome foliage and profusely produced fragrant yellow flowers. On account of its symmetrical pyramidal habit and its fast growth, it is well adapted for street planting.

Leaves large, alternate, entire, crowded toward the end of the branches: infl. a terminal loose panicle; sepals free; petals 5, with obovate blades and the long straight claws approximated into a tube; stamens 5; ovary incompletely 2-celled, cylindric, silky, with a short style: fr. a stipitate, compressed caps. with many compressed winged seeds. This monotypic genus is closely related to Pittosporum which differs chiefly in its thick, not winged seeds surrounded by a sticky substance wanting in Hymenosporum. Propagation is like that of Pittosporum by seeds or cuttings of half-ripened wood.

flàvum, F. Muell. (*Pittósporum flàvum,* Hook. f.). Shrub or tree, to 50 ft.: lvs. obovate, entire, to 9 in. long: fls. yellow, marked with red at the throat, fragrant, over 1 in. across: caps. compressed, 1 in. long and nearly as broad. B.M. 4799. R.H. 1913, p. 327.

Alfred Rehder.

HYMENÓXYS CALIFÓRNICA: *Actinolepis coronaria.*

HYOPHÓRBE (Greek, *food for swine,* referring to the fruits). *Palmàceæ,* tribe *Chamædòreæ.* Showy ornamental palms from Mauritius, often in trade collections, and well worthy wider cultivation.

Trunks unarmed, stout, either cylindric or in some species with a swelling beneath the lf.-cluster: lvs. terminal, equal, pinnatisect, the lfts. almost always opposite, and usually linear-lanceolate; margins recurved toward the base of the lft. and thickened throughout; petiole somewhat 3-angled and channelled: spadix short-stalked, many-branched, the branchlets spreading: fls. diœcious or in the different spadices sometimes monœcious, spirally arranged, pale yellow or greenish; sepals and petals 3, the latter small and broadly ovate; stamens 6: fr. somewhat inverted pear-shaped or olive-shaped.—There are only 3 or 4 species, and the genus is most closely related to Chamædorea, of horticultural palms, from which it differs in its usually diœcious fls. and in having the spadix below the lf.-cluster. I.H. 13:462, 463.

The two species in cultivation are ornamental palms, rather slow-growing and requiring much heat and moisture, and a night temperature of 65°. *H. Verschaffeltii* is much the better of the two species described below from a horticultural standpoint. Propagation is by seeds, which should be sown in a light compost or in pure peat with a bottom heat of 80°. The young seedlings are delicate and need protection from chills and over-watering.

amaricaùlis, Mart. (*Arèca speciòsa,* Hort.?). St. 60 ft. in nature, scarcely so tall in cult., with a bottle-shaped swelling near the base, usually abruptly narrowed near the lf.-cluster: petiole about a foot long, grooved and angled; lfts. 40–60 pairs, about 12–16 in. long and 2 in. broad: spadix about 12 in. long: seed elliptic, about ½in. long. Mauritius.

Verschafféltii, Wendl. (*Arèca Verschafféltii,* Hort.). Trunk 25–30 ft., about 6 in. diam., bulging about half way up: petiole about 3 in. long, slightly grooved on the upper surface and with a yellow band extending from the upper part of the lf.-sheath to the extremity of the blade, which is one of the chief horticultural attractions of the species; lfts. 30–50 pairs, about 2 ft. long and an inch wide: spadix as in the preceding, but the fls. orange: seed nearly cylindric, about ⅞in. long. Mauritius. G.W. 12, p. 207.

H. Commersoniàna, Mart. and *H. índica,* Gaertn. are both Chrysalidocarpus lutescens.

N. Taylor.†

HYOSCỲAMUS (Greek, *hog bean*). *Solanàceæ.* Henbane. A coarse, clammy, ill-smelling, wayside weed cultivated for medicinal purposes. An extract is commonly sold in drugstores.

Annual, biennial or perennial, mostly clammy pubescent: lvs. alternate, coarsely toothed, or pinnatifid, rarely entire: corolla pallid or lurid and netted-veined, funnel-shaped, with 5 unequal lobes; stamens mostly exserted, declined: caps. 2-celled, circumscissile above the middle. Henbane grows wild in Eu., W. Asia and Himalayas and is naturalized in Amer. It is found in sandy and waste places. The genus contains about 15 species, of the Old World.

nìger, Linn. Annual or biennial, 1–2½ ft. high: lvs. 3–7 in. long, the upper ones st.-clasping, irregularly lobed or pinnatifid: fls. greenish yellow, with purple veins, short-pedicelled or sessile, in leafy 1-sided spikes: caps. inclosed in the enlarging calyx.—The plant is said to be poisonous to domestic fowls but not to swine, although it is supposed the generic name has reference to harmful qualities to the latter animals. The lvs. and flowering tops are medicinal. The plant has no horticultural value. June–Sept. L. H. B.

HYOSÈRIS (*swine salad;* i.e., disagreeable or offensive). *Compósitæ.* Four species of nearly stemless herbs of S. Eu. and the Medit. region, one of which is sometimes grown as an alpine: allied to Krigia. Plant glabrous or glandular-pubescent: lvs. radical, pinnatifid: scape 1-headed, leafless, the heads yellow and homogamous; involucre cylindrical-campanulate, the inner bracts 1-rowed and equal, the outer ones few and short; receptacle plane and naked; corollas ligulate: achene glabrous. **H. fœ́tida,** Linn. (*Aposèris fœ́tida,* Less.), the species to be expected in the lists is by some authors retained in the genus Aposeris, distinguished by characters of the achene: perennial, much like Taraxacum, glabrous or somewhat pilose on veins on under side of foliage: lvs. runcinate-pinnatifid, the lobes about 10–12 pairs and somewhat triangular and sinuate-dentate: small plants in mountains of Eu. L. H. B.

HYÓSPATHE (*hog spathe:* i.e., hog palm, a vernacular name). *Palmàceæ.* Three S. American palms, little grown, with pinnatisect lvs. and unarmed reed-like sts.: fls. green, minute, the pistillate smaller than the staminate; stamens 6, and staminodia 6 in pistillate fls.: fr. small, ellipsoid or obovoid, purple. *H. élegans,* Mart., of the Amazon, one of the thatch palms, has sts. 1 in. diam. and 6 ft. high: lvs. 3–4 ft. long, at first nearly entire but becoming irregularly pinnate: fls. of both sexes borne in spikes beneath the terminal lvs. Other species sometimes referred to this genus belong to Prestoea and Pigafetta. L. H. B.

HYPÉCOUM (an old Greek name). *Papaveràceæ.* Annual herbs, sometimes grown in the flower-garden. Scapes erect, ascending or prostrate: lvs. radical and more or less rosulate, pinnately parted, the segms. pinnatifid or pinnately lobed, the floral lvs. less divided: fls. rather small, yellow or white; sepals 2, small, deciduous; petals 4, in 2 series, the outer ones often lobed, the 2 inner ones deeply 3-parted; stamens 4, opposite the petals: caps. narrow and silique-like, constricted between the seeds.—Species 15, according to the latest monograph (Fedde, in Engler's Pflanzenreich, hft. 40, 1909), in the Medit. region and east to China. They are of simple cult. under usual garden conditions. *H. procúmbens,* Linn. One foot: sts. or scapes ascending or becoming decumbent in fr.: lvs. glaucous-green, the basal ones 2-pinnatifid and the lobes very narrow and entire: fls. bright yellow, about ½in. across; outer petals somewhat 3-lobed but the side lobes very short. Medit. region to India. Variable. *H. grandiflòrum,* Benth. Six to 12 in., forking: lvs. with narrow linear segms. which are often lobed at top: fls. orange, about ½in. across, the outer petals with prominent side lobes. Medit. region to Asia Minor. L. H. B.

HYPÉRICUM (*Hypereikon,* ancient Greek name of a plant, of obscure meaning, possibly derived from *ereike,* heather, with the prefix *hypo,* beneath). *Hypericàceæ,* often united with *Guttiferæ.* St. John's-Wort. Ornamental shrubby or herbaceous plants chiefly grown for their bright yellow flowers; planted in the open; often with interesting foliage and habits.

Deciduous, or sometimes evergreen, usually low shrubs, or herbaceous perennials, rarely annual: lvs. opposite, short-petioled or sessile, entire, dotted with pellucid or opaque glands, without stipules: fls. usually in terminal cymes, less often solitary, sometimes axillary, yellow, rarely pink or purplish; sepals 5, imbricate or valvate, often unequal; petals 5, oblique, convolute in bud; stamens usually numerous, free, or connate at the base into 5 or 3 bundles, rarely as few as 3; ovary superior, with 3–5 parietal placentæ, 1–5-celled; styles 3–5, distinct or united: fr. a septicidal caps., rarely a berry; seeds usually cylindric, many, rarely few.—About 200 species in the temperate and subtropical regions of the northern hemisphere, few in the southern hemisphere.

The St. John's-worts are exceedingly variable in habit; most species in cultivation are low shrubs, either upright with ascending or spreading branches, or tufted or procumbent; the herbaceous species have often stiff upright wand-like stems or are diffuse or procumbent: the leaves are usually narrow and rather small; the yellow, rarely pink or purplish flowers appear usually in profusion during the summer in terminal clusters, less often solitary, sometimes axillary and forming leafy racemes or panicles; they vary from ⅕ inch to 3 inches in diameter; the capsular fruits are inconspicuous or even unsightly when ripe, only the fruits of the one berry-bearing species are ornamental. Most of the species are tender in the North. *H. aureum, H. prolificum, H. lobocarpum,* and other American species, also *H. calycinum* and *H. patulum* var. *Henryi,* with some protection, have proved hardy as far north as Massachusetts, and *H. Kalmianum* and *H. Ascyron* are still hardy in Canada. Others like *H. patulum, H. Hookerianum, H. Moserianum, H. chinense* can be relied upon only south of New York. *H. floribundum* is doing well in California and so will probably the other Mediterranean species.

They thrive in any good loamy soil, and also in sandy soil, if sufficiently moist; most of them prefer partly shaded situations and bloom longer if not exposed to the full sun. They are, as a rule, short-lived plants and ought to be renewed when they show signs of exhaustion. The larger kinds are well adapted for borders of shrubberies and form round rather dense bushes when standing alone, while those like *H. calycinum, H. Buckleii* and *H. adpressum* are suited for low borders or as a ground-cover, particularly *H. calycinum* which spreads rapidly by suckers. Many of the low tufted or prostrate species enumerated in the supplementary list are handsome plants for rockeries where the more tender species can be so planted as to be easily protected during the winter. Propagation is by seeds, which germinate readily, the shrubby species also by greenwood cuttings under glass in summer; the creeping kinds as *H. calycinum* and some herbaceous species also by division and suckers.

Section Roscyna.

1. **Áscyron,** Linn. (*H. pyramidàtum,* Dry.). Upright perennial, 2–6 ft. high, with tetragonal sts.: lvs. clasping, ovate-oblong or ovate-lanceolate, acutish, 2–5 in. long: cymes terminal, 3–12-fld., appearing in July; fls. 1–2½ in. diam.; sepals ovate to ovate-oblong, unequal; petals thin, narrowly obovate or oblanceolate, curiously shaped and twisted, persistent until withered; stamens in 5 clusters; styles somewhat spreading; stigmas capitate: caps. ovoid, ¾in. long. N. E. N. Amer., Cent. and E. Asia. B.B. (ed. 2) 2:529.—A somewhat coarse plant and toward fall apt to be unsightly through the lower lvs. dying and remaining. Var. **Vilmorínii,** Rehd. Fls. 3–4 in. across. Recently raised by M. L. de Vilmorin from seeds obtained from Korea. B.M. 8557.

Section Eremanthe.

2. **calycìnum,** Linn. Rose of Sharon. Aaron's Beard. Fig. 1940. A subshrub, 1 ft. or less high, with many procumbent or ascending 4-angled sts. occurring in thick tufts: lvs. ovate-oblong or oblong, obtuse, evergreen, subcoriaceous, dark green, glaucous below, 2–4 in. long: fls. large, solitary, or 2–3 together, 3 in. diam.; sepals large, obovate, spreading; stamens long and showy, in 5 clusters, with red anthers; styles shorter than the stamens, divergent: caps. ovate, 4 in. long. July–Sept. B.M. 146. G. 25:333. G.W. 1, p. 197.—A rapidly spreading plant, creeping by woody rootstalks completely covering the soil. Used as a ground-cover abroad. Not very hardy in New England, the annual killing back preventing its covering wide stretches, but not destroying its bloom each year, nor its usefulness in the herbaceous border, or in the margin of a shrubbery. May be protected, and its dark, persistent foliage preserved. Thrives in sun and moderate shade.

1940. **Hypericum calycinum.** (×¼)

3. **cérnuum,** Roxbg. (*H. oblongifòlium,* Choisy). Shrub, to 5 ft., with terete branches: lvs. sessile, narrowly elliptic to ovate-lanceolate, acutish, narrowed at the base, glaucous beneath, 1–3 in. long: fls. pale yellow, nearly white when opening, 2 in. across, long-stalked, nodding, solitary or in cymes of 3–5; sepals acute; petals obovate; stamens little shorter than petals. Himalayas.—Cult. in Calif.

Section Norysca.

4. **chinénse,** Linn. (*H. monógynum,* Willd.). Half-evergreen shrub to 2 ft., with terete branchlets: lvs. sessile, oblong, obtuse, 1½–3 in. long: fls. about 2 in. across; sepals ovate-oblong, obtuse; petals broadly obovate; stamens little shorter than petals; style slender, about ¾in. long, 5-parted at the apex. China. B.M. 334. G.C. III. 1:705.—Tender.

5. **Hookeriànum,** Wight & Arn. (*H. oblongifòlium,* Hook., not Choisy). A rather compact shrub, to 6 ft., with terete bright reddish brown branches: lvs. among the largest of the genus, 1–4 in. long, evergreen, ovate or oblong, sessile, dark blue-green above, pale and glaucous below: corymbs several-fld., of large golden yellow

fls. in profusion, 2–2½ in. diam.; sepals large, obovate; petals very large, firm, broadly obovate; stamens scarcely half as long as petals; styles recurved, longer than the stamens: caps. broad-ovate, longitudinally furrowed, ¾in. long. Aug. Himalayas. B.M. 4949. Gn. 54, p. 490. G. 3:463. This is one of the most showy species. Var. **Leschenaúltii,** Dyer (*H. triflòrum,* Blume). Of slenderer and more graceful habit: fls. 2½ in. across; sepals acute. Himalayas, Java. Gn. 23:158.

6. **pátulum,** Thunb. An evergreen spreading shrub, 1½–3 ft. high, with many smooth, purplish, arching 2-edged branches: lvs. ovate-lanceolate or ovate-oblong, acutish, 1½–2 in. long: fls. many, solitary or in cymes, large, 1½–2 in. diam., of good substance; sepals suborbicular, longer than half the petals; styles upright: caps. ovate, more or less longitudinally furrowed, ½in. long. July–Sept. Japan. B.M. 5693. J.H. III. 43:405. Gn.W. 21:95. R.H. 1875:170. Gt. 15:513. Var. **oblongifòlium,** Koehne (*H. oblongifòlium,* Wall.). Lvs. 2–4 in. long, bluish gray beneath, acutish: fls. 1¾in. across; sepals shorter than half the petals. Himalayas. Var. **urâlum,** Koehne (*H. urâlum,* Don. *H. nepalénse,* Hort.). Lvs. about 1 in. long, acute or acutish: fls. ¾–1 in. across; sepals shorter than half the petals. Himalayas. B.M. 2375. Gn. 17, p. 53. The name has no connection with the Ural Mts., but is an adaptation of the native name "urala swa." Var. **Hénryi,** Veitch. Lvs. ovate or ovate-oblong, obtuse, 2–3 in. long: fls. 2–2½ in. across; sepals ovate, acute. China. This variety is hardier than the other forms of this species and of more vigorous growth.

7. **Moseriânum,** André. Gold Flower. Hybrid raised by Moser, of France, from *H. patulum* and *H. calycinum,* generally resembling the latter but lacking its coarseness, and surpassing both parents in good qualities. A glabrous subshrub 2 ft. high, erect, with the tips of the branches pendulous: lvs. similar to those of *H. calycinum,* ovate, obtuse and mucronulate, opaque, 2 in. long, dark green above, pale below: infl. with 1–3 fls. to the stalk, which are golden yellow, 2–2¾ in. diam., blooming for some time; sepals foliaceous, unequal, oval to oblong; corolla of broad rounded petals, their color heightened by the many tufted yellow stamens with reddish anthers: caps. top-shaped. July, Aug. R.H. 1889, p. 464. Gn. 54:490. R.B. 16:97. G.C. III. 10:333.—Not hardy in New England, but successful farther south. Not good individually, but good in masses, better adapted to the herbaceous border than the shrubbery. May be used as a pot-plant. Var. **trícolor.** Variegated form of white and green edged with red. Habit like *H. patulum,* but more horizontal, the lvs. smaller and narrower: fls. one-fourth the size of those of *H. Moserianum* but similar. Less hardy. J. 8, p. 186.

Section Myriandra.

8. **lobocárpum,** Gattinger. Upright shrub, to 6 ft.: lvs. oblong-lanceolate or linear-lanceolate, obtuse or barely acute, 1½–2½ in. long: fls. profuse, ⅓–½ in. across, in many-fld., naked cymes, forming a corymbose or elongated panicle; sepals oblong, obtusish; stamens numerous; styles connivent: caps. oblong, 5-angled, furrowed, ¼in. long. Aug. Tenn., where it frequents marshes. G.F. 10:453.

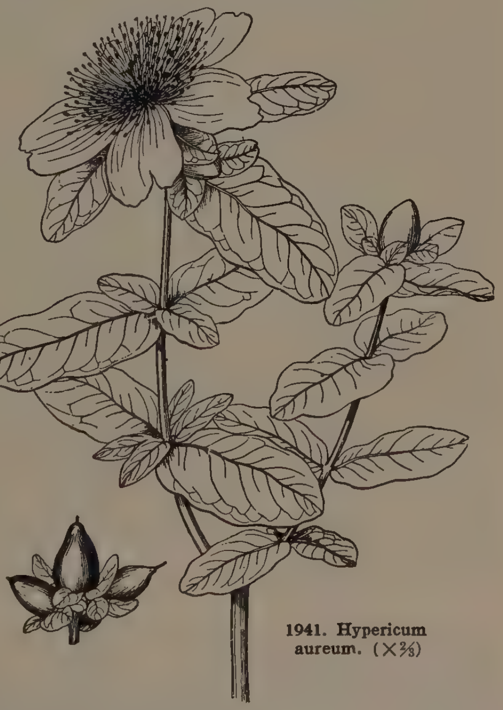
9. **Kalmiânum,** Linn. A shrub, 2–3 ft. high, with rather contorted sts.: lvs. oblong-linear, or oblanceolate, 1–2½ in. long, bluish, more or less glaucous below, crowded: fls. small, ½–1 in. diam., in 3- to several-fld. cymes; sepals foliaceous, oblong, acute; styles united below to form a beak: caps. ovoid, longitudinally furrowed. Aug. Ont. and W. N. Y. to Ill. and Wis. B.M. 8491. G.F. 3:113. Mn. 6:141.—Easily adapted to the garden, succeeding in the shade and enduring considerable dryness. Not so showy in fl. as some other species, but good because of its bright, narrow lvs. and hardiness.

10. **glomerâtum,** Small. Shrub, to 3 ft.: lvs. sessile, narrowly oblong to narrowly linear, apiculate, paler beneath, ¾–1½ in. long: fls. bright yellow, ¾–1 in. across, in dense cymes at the end of the branchlets; sepals rather foliaceous, narrowly oblong, acutish: petals cuneate-spatulate: caps. slightly lobed. Aug. N. C.

11. **densiflòrum,** Pursh (*H. prolíficum* var. *densiflòrum,* Gray). Shrub, to 6 ft.: lvs. short-petioled, linear-oblong to linear, revolute, acute, ½–2 in. long: fls. bright yellow, about ½in. across, in broad and dense, many-fld. corymbs; sepals unequal, oblong to elliptic-oblong: caps. ovoid, slightly 3-lobed. July–Sept. N. J. to Fla., Mo. and Texas. B.B. (ed. 2) 2:530. Mn. 4:97. G.F. 3:527. R.H. 1899, pp. 517, 518.

12. **galioìdes,** Lam. (*H. axillàre,* Lam., not Michx.). Shrub with slender sts. to 3 ft.: lvs. sessile, ¼–¾in. long, linear, acute, dark green, crowded: fls. yellow, ¼–½in. across, axillary, solitary or in small cymes, forming narrow leafy panicles; sepals linear or linear-spatulate; petals cuneate at the base: caps. conic, acute, furrowed, incompletely 3-celled. July–Sept. Del. to Fla., Mo. and Texas. G.F. 10:433. G.C. III. 24:301.—Forms usually a low round bush with handsome dark green foliage.

13. **prolíficum,** Linn. (*H. foliòsum,* Jacq. *Myriándra prolífica,* Spach). A stout, dense shrub, to 5 ft. high, with exfoliating light brown bark, the twigs 2-angled: lvs. narrowly oblong or oblanceolate, obtuse, 1–3 in. long, glossy, dark green, pellucid-punctate: fls. in profusion, ½–1 in. wide, in several- to many-fld. axillary cymes; sepals obovate; stamens numerous, distinct; styles united at the base: caps. large, oblong, ½in. long, not furrowed. July–Sept. Found in sandy or rocky soil, N. J. to Iowa and Ga.; one of the most commonly cult. G.F. 3:526. W.D. B. 2:88.—A strong, hardy shrub. Grows rapidly in ordinary garden soil, flowering regularly and profusely. Varies greatly in size.



1941. Hypericum aureum. (×⅔)

14. **aùreum,** Bartram (*H. prolíficum* var. *aùreum,* Koehne). Fig. 1941. Showy shrub 3 ft. high, more

woody than most species, of stiff, dense habit, top often globular like a miniature tree, with thin, exfoliating red bark, the branchlets 2-edged: lvs. ovate-oblong to oblong, mucronate, bluish, pale below, leathery, 1–3 in. long: fls. sessile, solitary in the native state, in cymes of several in cult., 1–2 in. diam., bright yellow, heightened by the golden filaments at the center; sepals lf.-like, obovate, very unequal, shorter than the thick, broad petals, which persist until withered; stamens distinct, very numerous; styles connate: caps. ovate, acuminate, red, not furrowed, nearly ½in. long. July–Aug. Affects rocky situations when wild, generally shady, where moisture is longest retained, from S. C. to Tenn., Ga. and Texas, but perfectly hardy in Mass. B.M. 8498. Gn. W. 20:934. G.F. 2:185 (adapted in Fig. 1941).—Prop. by seeds and cuttings, young plants from seed blooming the second year.

15. **nudiflòrum,** Michx. Shrub or subshrub, 1–3 ft.: branchlet 4-angled: lvs. sessile, elliptic-oblong to elliptic-lanceolate, obtuse, flat, thin, pale above and below, 1–2½ in. long: fls. light yellow, ½–¾in. across, in naked, peduncled, loose corymbs 2–5 in. broad; sepals elliptic-oblong to elliptic-oblanceolate; styles united: caps. conic-ovate, ¼in. long. July–Aug. N. C. to Fla. and Ala.

16. **Búckleii,** Curtis. Later written *Buckleyi*. Dense shrub, with slender, 4-angled sts. forming neat, rounded tufts not more than 1 ft. high: lvs. bluish, obovate to elliptic, ¼–1 in. long, rounded at the apex, gradually narrowed at the base, pale below, becoming scarlet in autumn: fls. solitary or in cymes of 3, 1 in. diam.; sepals obovate, obtuse; petals striated and strap-shaped; styles connate: caps. conic-ovoid, about ⅓in. long. June, July. Found only in the highest mountains of the Carolinas and Ga. G.F. 4:581.—Adapted to rockeries and margins of small shrubberies.

17. **adpréssum,** Bart. (*H. fastigiàtum*, Ell.). Practically a herbaceous perennial, erect from a creeping or decumbent base, growing in dense masses, ½–2 ft. tall: lvs. oblong or lanceolate, 1–2 in. long, acute, thin: fl. yellow, ½in. across in several-fld. terminal cymes; sepals lanceolate or ovate-lanceolate: caps. ovoid, slender-beaked. July, Aug. Moist places, Nantucket, Mass. to Ga. and La. B.B. (ed. 2) 2:531.—Spreads rapidly by underground stolons, suggesting occasional use as a ground-cover. Not very hardy in New England.

18. **cistifòlium,** Lam. (*H. sphærocárpum*, Michx.). Upright perennial or subshrub, with 4-angled sts., 1–3 ft. high: lvs. sessile, often slightly clasping, oblong or linear-oblong, obtuse, revolute, 1–3 in. long: fls. yellow, ½in. across, nearly sessile, in terminal, loose corymbs; sepals ovate to lanceolate: caps. globose to globose-ovoid, 1-celled. July–Sept. Ohio to Ill., Ala., and Ark. B.B. (ed. 2) 2:532.—Satisfactory in light, sandy soil. Spreads rapidly by stoloniferous roots, covering the soil and preventing washing. Not very ornamental. Half-hardy N.

Section EUHYPERICUM.

19. **perforàtum,** Linn. Herbaceous perennial, 1–2 ft., with upright, 2-edged sts.: lvs. sessile, oblong to linear, obtuse, black-dotted, ½–1 in. long: fls. bright yellow, ½–1 in. across, in terminal cymes; sepals acute; stamens in 3 fascicles: caps. ovoid, glandular. June–Sept. Eu., now commonly naturalized in fields and waste places. B.B. (ed. 2) 2:533. R.F.G. 6:343 (5177).

Section WEBBIA.

20. **floribúndum,** Dry. A subshrub, with round, glabrous sts.: lvs. lanceolate-elliptic, rounded at the base; light green; without dots, 1–1½ in. long: fls. in terminal, many-fld. panicles, 1½–2 in. diam., with dilated peduncles; sepals ovate-lanceolate, somewhat acute; stamens numerous, in 3 fascicles, petals and stamens persistent; ovary oval; styles long, divergent, with capitate stigmas. From the Canary and Madeira Isls.—Not hardy N., but in cult. in S. Calif. Grows very rapidly to the height of about 12 ft. or more, but it is usually kept lower by topping it after blooming and thus making it bloom again in about two months. Generally prop. from seeds, which are produced freely.

Section ANDROSÆMUM.

21. **hircìnum,** Linn. Glabrous subshrub of round, compact habit, 2–3 ft. high, the branches winged toward the tips: lvs. sessile, ovate-lanceolate, acute, glandular, 1–2½ in. long, deep green: fls. 1–1½ in. wide, solitary or 3-clustered; sepals lanceolate, deciduous, one-third to one-fourth the length of the lance-oblong petals, which are of a deeper yellow than in the other species; stamens very long, in 5 fascicles; styles spreading, longer than the stamens: caps. ovoid, pointed. July, Aug. W.D.B. 2:86.—Species characterized by the strong, goat-like odor of the lvs. (hence the name). Of easy cult., but requiring a dry position and winter protection. Medit. region. Var. **pùmilum,** Wats. (var. *mìnor*, Lav.). Dwarfer, with smaller lvs. and fls.; as pretty and free-blooming as the type, and, in the rock-garden, preferable. W.D.B. 2:87.

22. **elàtum,** Dry. (*H. grandifòlium*, Choisy. *H. multiflòrum*, Hort., not HBK. *Andrósæmum Webbiànum*, Spach). Shrub or subshrub, 3–4 ft. high, with slightly 2-edged branchlets: lvs. ovate-oblong, acute or obtusish, often subcordate at the base, 1½–3 in. long: fls. 1–1½ in. across, in several- to many-fld. terminal panicles; sepals ovate or ovate-lanceolate, obtuse or sometimes acutish, about ¼in. long; stamens in 5 fascicles; styles longer than ovary: caps. ovate-oblong. July. Canary Isls., Madeira. R.F.G. 6:352. W.&.B. 2:85.—*H. multiflòrum*, Hort., has been considered a hybrid between *H. elatum* and *H. Androsæmum*, but the plant cult. at the Arnold Arboretum does not show any influence of the latter species and is apparently only a form of *H. elatum* with more numerous and somewhat smaller fls.

23. **Andrósæmum,** Linn. (*Andrósæmum officinàle*, All.). SWEET AMBER. COMMON TUTSAN. A dense undershrub with erect, 2-edged sts.: lvs. ovate to ovate-oblong, 2–4 in. long, subcordate, minutely dotted, dark green, whitish below: fls. solitary or in cymes of 3–9, large, light yellow, 1 in. across; sepals ovate, ⅓–½in. long; stamens in 5 clusters, longer than the petals; ovary subglobular or oval, incompletely 3-celled; styles divergent, persistent, shorter than ovary: fr. berry-like, blackish violet, the size of a pea. June–Sept. Lives in shady, wet places, W. and S. Eu. to Persia.—Not yet proved hardy at the N. Fls. not particularly attractive, but good in fr. and foliage. All parts very aromatic.

Section ELODEA (Triadenum).

24. **virgínicum,** Linn. (*Triadènum virgínicum*, Raf. *Elodèa campanulàta*, Pursh. *Elodèa virgínica*, Nutt.). MARSH ST. JOHN'S-WORT. Smooth perennial, 1–1½ ft. high, nearly simple: lvs. numerous, oblong or oval, cordate, clasping, rounded, 1–2½ in. long: fls. ½in. diam., pink- or flesh-colored, in small, close cymes; sepals equal; petals oblong; stamens at least 9 in 3 sets; styles distinct: caps. oblong. July, Aug. In swamps, Labrador to Fla. west to Man., Neb. and La. B.B. (ed. 2) 2:537.—Useful plant for an artificial bog, and thrives well also in any fine, loamy soil in the shade or sun.

H. ægyptiacum, Linn. Dwarf shrub: lvs. crowded, elliptic, acute, ¼–⅓in. long: fls. solitary, axillary ⅓–½in. across, forming leafy racemes; styles 3. Medit. region. B.M. 6481. G.C. II. 14:503. B.R. 196.—*H. Arnoldiànum*, Rehd. (H. galioides × H. lobocarpum). Similar to H. galioides, but with a many-fld. terminal infl. and several-fld. lateral infl.: caps. 3–5-celled. Originated at the Arnold Arboretum.—*H. baleàricum*, Linn. Low upright shrub with the lvs. beneath and the twigs warty: lvs. oval, obtuse, about ⅓in. long: fls. 1½ in. across, solitary, terminal; styles 5. Medit. region.

B.M. 137.—*H. canariénse*, Linn. Allied to H. floribundum. Shrub, to 15 ft.: lvs. oblong-lanceolate, narrowed at the base, 2–3 in.: fls. 1–1⅓ in. across, in panicles; sepals ovate, acute, ciliate. L.B.C. 10:953.—*H. còris*, Linn. Procumbent subshrub, 6–8 in. high: lvs narrowly linear, revolute on the margin, about 1 in. long, in whorls of 4–6: fls. ¾in. across, in few-fld. loose cymes; styles 3. Cent. and S. Eu. B.M. 6563.—*H. cuneàtum*, Poir. Low diffuse subshrub, ½–1 ft. high: lvs. obovate, ¼–⅓in. long: fls. ¾in. across, axillary, slender-stalked, forming leafy racemes. Asia Minor. —*H. Dawsoniànum*, Rehd. (H. lobocarpum × H. prolificum). Differs from H. prolificum in the more numerous fls. and the 3–5-celled, furrowed caps. Originated at the Arnold Arboretum.—*H. dolabrifórme*, Vent. Procumbent perennial, with ascending sts. 6–20 in. high: lvs. linear-lanceolate, ½–1½ in. long: fls. 1 in. across, in terminal leafy corymbs. Ky. and Tenn. B.B. (ed. 2) 2:532.—*H. èlegans*, Steph. Upright perennial, ½–1 ft. high.: lvs. ovate-lanceolate, ¾–1 in. long: fls. ¾–1 in. across, in terminal panicles; sepals ovate-lanceolate, glandular-ciliate. Cent. Eu. to Altai Mts. R.F.G. 6:350 (5190).—*H. elòdes*, Huds.=H. helodes, Linn.—*H. empetrifòlium*, Willd. Upright shrub, to 1 ft.: lvs. linear, revolute on the margin, ½–¾in. long, in whorls of 3: fls. ½–¾in. across, in 3–5-fld. cymes forming panicles; sepals broadly oblong. S. E. Eu., Asia Minor. B.M. 6764. Gn. 30, p. 221.—*H fasciculàtum*, Lam. Allied to G. galioides. Shrub, to 6 ft.: lvs. linear, thick, ½–¾ in. long: fls. ⅓–½ in. across, in narrow panicles. N. C. to Fla. and Texas.—*H. fràgile*, Heldr. & Sart. Dwarf subshrub: lvs. ovate, imbricate, ⅙in. long, glaucescent-fls. large, in 3- to many-fld. cymes; sepals linear-lanceolate. Greece.—*H. helòdes*, Linn. Procumbent perennial, with orbicular-ovate, villous lvs. ⅓–¾in. long: fls. pale yellow, about ⅓in. across; in few-fld. terminal cymes. Eu. R.F.G. 6:342 (5182). Suitable for boggy places.—*H. inodòrum*, Willd. (H. ramosissimum, Ledeb.). Allied to H. hircinum, but without the goat-like odor. Arching shrub, with strongly 2-edged branchlets: lvs. ovate to ovate-oblong, 1½–2 in. long: fls. 1 in. across, in few-fld. dense corymbs. Caucasus.—*H. japónicum*, Thunb. Decumbent perennial, with ovate or oval 3-nerved lvs. and 4-angled sts.: fls. ¼in. across, with petals equaling the lanceolate sepals, in terminal cymes. E. Asia to Austral. Scarcely ornamental.—*H. lysimachioìdes*, Wall. Slender shrub, with slightly angular arching branchlets: lvs. ovate to ovate-oblong, acute, 1–1½ in. long: fls. 1 in. across in loose leafy cymes; sepals linear-lanceolate; styles 5. Himalayas. V.F. 25.—*H. montànum*, Linn. Perennial: lower lvs. larger, ovate, glabrous: fls. in close compact cymes, often reduced to a head. Cent. and S. Eu.—*H. napauléns*e, Choisy (H. nepalensis, Hort.). Trailing subshrub with ovate to ovate-lanceolate lvs. ½–¾in. long: fls. ⅓in. across in few-fld. loose cymes. Himalayas.—For H. nepalense, Hort., see also No. 6.—*H. nóthum*, Rehd. (H. densiflorum × H. Kalmianum). Similar to H. densiflorum, but fls. less numerous, lvs. narrower and caps. 3–5-celled, slightly furrowed. Originated at the Arnold Arboretum.—*H. nummulàrium*, Linn. Diffuse ascending subshrub: lvs. roundish, ⅓–½in. long: fls. ¾in. across, in terminal cymes; sepals glandular-ciliate. Pyrenees. R.F.G. 6:346 (5184).—*H. olýmpicum*, Linn. Upright or ascending subshrub, 1 ft.: lvs. oblong-lanceolate, grayish green, ½–1½ in. long: fls. golden yellow, 1½–2½ in. across, in terminal few-fld. corymbs; sepals large, pointed; petals oblong-obovate. S. E. Eu., Asia Minor. B.M. 1867. Gn. 31:302.—*H. opàcum*, Torr. & Gray. Allied to H. sphærocarpum. Subshrub, 1–3 ft.: lvs. oblong-lanceolate, ½–1 in. long: fls. ⅓in. across, in open corymbs; sepals obtuse: caps. ovoid. S. C. to Fla. and Miss. G.F. 5:305.—*H. orientàle*, Linn. Upright perennial, ½–1 ft.: lvs. obovate-oblong to linear-oblong, obtuse, glandular-ciliate, ½–1 in. long: fls. 1 in. across, in small terminal cymes. Asia Minor.—*H. polyphýllum*, Boiss. Perennial with ascending sts.: lvs. elliptic-linear, glaucous, ⅕–⅓ in. long: fls. 1½–2 in. across, in dense terminal cymes. Cilicia.—*H. púlchrum*, Linn. Allied to H. perforatum. Sts. terete: lvs. ovate, clasping, ⅓–½in. long: fls. ½–¾in. across, in terminal panicles; sepals glandular-ciliate. Cent. Eu. R.F.G. 6:347 (5185).—*H. ramosíssimum*, Ledeb.=H. inodorum.—*H. rèpens*, Linn. Perennial, with prostrate sts.: lvs. oblong or linear-oblong, ¼–⅓in. long: fls. golden yellow, 1 in. across in few-fld. terminal cymes. S. E. Eu., Asia Minor. S.F.G. 8:775.—*H. rèptans*, Hook. f. & Thoms. Prostrate shrub, with rooting sts.: lvs. elliptic-oblong, ¼–½in. long: fls. cup-shaped, solitary, terminal, 1¾in. across; petals broadly obovate; styles 5. Himalayas. Gn. 24, p. 267; 30, p. 221. —*H. salicifòlium*, Sieb. & Zucc. Allied to H. chinense, but distinguished by the narrower acute lvs., many-fld. corymbs and acute sepals. Japan.—*H. spléndens*, Small. Allied to H. aureum. Shrub, to 5 ft.: lvs. oblong, ¾–1 in. long: fls. pedicelled, 1½ in. across, in several- to many-fld. cymes; stamens orange-colored: caps. with 3 narrow wings Ga. Seems not yet in cult.; very desirable.—*H. tomentòsum*, Linn. Perennial with ascending sts.: lvs. ovate, woolly, ⅓–¾in. long: fls. ½–¾in. across, in many-fld. corymbs; sepals ciliate, acute. Eu. R.F.G. 6:346 (5183).—*H. túrgidum*, Small. Allied to H. sphærocarpum. Shrub, 1–2 ft.: lvs. linear-oblanceolate, ½–1 in. long: fls. 1 in. across in several-fld. cymes; sepals ovate to elliptic: caps. subglobose, broadest at the top. Ala.

ALFRED REHDER.†

HYPHÆNE (Greek, *to entwine;* referring to the fibers of the fruit). *Palmàceæ*, tribe *Borásseæ*. Fan-leaved unarmed palms of moderate or tall stature from tropical Africa and Madagascar.

Caudex robust, cylindrical, ventricose or pear-shaped, simple or forkingly branched: lvs. terminal, orbicular, palmate-flabelliform, plicate-multifid; segms. ensiform, acute or 2-fid, margins induplicate with fibers interposed; rachis short; petiole strongly biconvex or a trifle flatter above; margins minutely spiny; ligule short, rotund; sheath short, open: fls. diœcious, in relatively deep pits, on the infl., which is partly hidden by the lvs.—About 10 species from Trop. Afr. The Borassus tribe of palms consists of Borassus, Lodoicea, Latania and Hyphæne. In the first two the staminate fls. in the pits of the spadix are numerous; in the last two they are solitary. In the first and fourth there are few stamens; in the second and third the stamens are numerous.

crinìta, Gaertn. (*H. natalénsis*, Kunze). Young fronds 1 to 1½ ft. long, lanceolate, bi- or trifid at the apex, bright green, clothed on both sides with a white bloom which soon vanishes, plicate, scabrous on the margins and nerves above; petiole sheathed for 1 or 2 in., deeply channelled above, rough on the margins: frs. obovate, 2½ in. long, smooth. S. Afr.—Cult. outdoors in S. Fla. Does not look at all like Latania. It has long, thick seed-lvs., and, it is said, has withstood the cold in Fla. better than any other palm. It is extremely slow of growth, and cannot be desirable as a house plant. It is probably cult. more in northern conservatories than in the S.

H. thebàica, Mart. A showy palm with striking yellow-orange frs. is probably a Corypha. It is little cult. in N. Amer. F.S. 21:2152–3.—*H. ventricòsa*, Kirk, is a showy blue-green palm with an immense cluster of lvs. and a bulging trunk. Congo. Not in cult. in Amer. G. C. II. 21:649.

N. TAYLOR.†

HYPOCHÈRIS (old name, of doubtful origin). *Compósitæ*. Sometimes written with the digraph *æ*. Perhaps 50 herbs, of the Medit. region, N. Asia and the southern part of S. Amer., allied to Leontodon, scarcely cult. They are annual or perennial, more or less branched, yellow-fld.: lvs mostly radical: involucre campanulate, the scales marginless; receptacle with narrow bracts: achenes 10-ribbed, some or all tapering into a beak; pappus of many fine plumose bristles; heads homogamous, the florets ligulate. **H. uniflòra,** Vill. (*Achyróphorus helvéticus*, Scop. & Less.), has been offered in N. Amer.: perennial: radical lvs. oblong-lanceolate, dentate, hirsute; cauline lvs. 1–2: st. simple, 1-headed or sometimes 2–3-headed under cult.: involucre very hairy: achenes beaked. Mountains of Eu., and useful in alpine- and rock-gardening.

L. H. B.

HYPOCÝRTA (name refers to the gibbous or *curved beneath* corolla-tube). *Gesneriàceæ*. Shrubby, erect, creeping or climbing, natives of tropical America of perhaps ten species. They are little known in cultivation; require the handling of Gesneria and similar plants. *H. grácilis*, Mast.=*Codonanthe gracilis.*

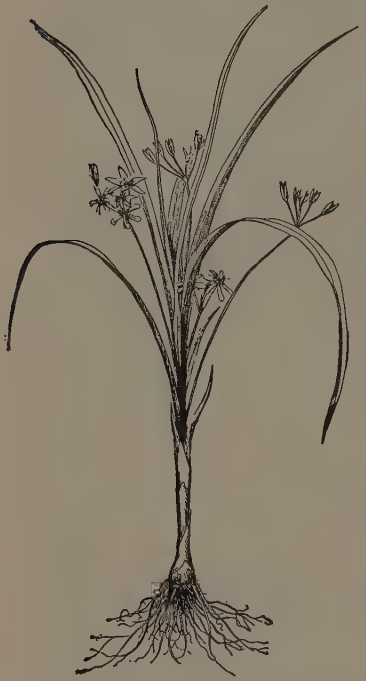
HYPÓLEPIS (Greek, *a scale underneath*). *Polypodiàceæ*. Tropical glasshouse ferns of both hemispheres rarely cult. Allied to Cheilanthes: rhizomes long and creeping, the fronds herbaceous: distinguished particularly by the marginal sori, placed in the sinuses of the lf., and covered with the membranous lf.-margin.—Ten or more species are known. (See p. 1215.)

rèpens, Presl. Lf.-stalks straw-colored, more or less prickly; lf.-blades 3–4 ft. long, quadripinnatifid; lower pinnæ 1–2 ft. long, 6–12 in. wide, ovate-acuminate; sori 2–6 to a segm. W. Indies to Brazil.—A rather coarse fern, of easy cult., with the general appearance of a cyathea. Like all strong-growing ferns, it requires a large percentage of loam. It likes shade and moisture at all times, and is readily prop. by spores, which it produces in great quantity, being often self-sown. It requires a stove or intermediate temperature.

H. califórnica, Hook. See Cheilanthes californica.—*H. meifòlia*, Baker. See Cheilanthes meifolia.

L. M. UNDERWOOD.

HYPOLÝTRUM (from the Greek for *beneath* and a *sheath;* in reference to the 2 or 3 scales found under the true scale). *Cyperàceæ*. Perennial herbs with leafy sts., often very strong and coarse: spikelets numerous and small in compound panicles that have long leafy involucral bracts; glumes imbricate around the rachis; stamens 3 or less: fr. a hard 3-angled nutlet.—Species 25 or 30, in tropical and subtropical regions of both hemispheres. Only one species seems to be in the trade. **H. Schraderiànum,** Nees, is listed abroad, apparently as a greenhouse plant, the lvs., "crowded in bold triangular tufts, green with purplish red margins, traversed on the upper surface by 2 ribs running equidistant from base to apex," giving it a striking and ornamental effect: panicle much decompound; spikelets obovate-elliptic: lvs. linear-lanceolate, 3-nerved, the margin and midnerve more or less serrulate-scabrous toward the apex, 2 ft. long and 1½ in. or less wide: culms 5–6 ft. In woods and swamps, Brazil. L. H. B.



1942. Hypoxis hirsuta.

HYPÓXIS (old Greek name, of no application to these plants). *Amaryllidàceæ.* Star-Grass. About 50 species of little herbs of temperate and tropical regions, with linear lvs., hard rootstocks or corms, perianth adnate to the ovary, and anthers not versatile: stemless: fls. few, on slender scapes. They are scarcely known in cult., although the common species of the northern states, **H. hirsùta,** Coville (*H. erécta,* Linn.), Fig. 1942, is offered by dealers in native plants. The lvs. are radical, hairy, grass-like: fls. 1–6, small, star-like, bright yellow, on scapes 4–10 in. tall. Give a half-shady place in the rockery or border. Prop. by division. Blooms in spring. Not showy, but interesting. **H. stellàta,** Linn. f., from S. Afr., is a pretty greenhouse bulb, blooming in Dec.: lvs. 4–12, glabrous, a foot or less long: peduncles sometimes forked, 1–4, bearing fls. white inside, and the outer segms. green-striped on the back: corm globose: plant variable. L. H. B.

HÝSSOPUS (ancient name; but precisely what plant was the sacred Hyssop of the Jews is uncertain). *Labiàtæ.* Hyssop. A familiar plant, cultivated for medicine and also for ornament in hardy borders.

It is considered a genus of only 1 species, the numerous synonyms being referred mostly to *H. officinalis* or to the genus Lophanthus, 2 species of which are cult. Hyssopus has entire lvs.: Lophanthus has serrate lvs. Important generic characters of Hyssopus are the 15-nerved tubular calyx, divergent stamens, upper lip of corolla 2-lobed, lower 3-lobed, stamens 4, didynamous, nutlets ovoid and smooth and somewhat 3-sided.

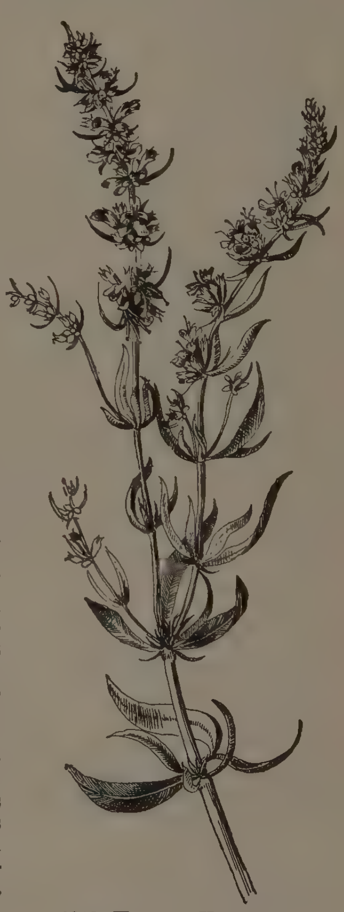
officinàlis, Linn. Fig. 1943. Sts. herbaceous from a woody base, slender, branched or not: lvs. linear to oblong, sessile or nearly so, acute at both ends or the lower ones obtuse at the apex, 1½–2 in. long. Eu. and Temp. Asia; also run wild in this country. B.M. 2299 (as *H. orientalis*). Var. **álba,** with white fls., is cult. Var. **grandiflòrus,** Hort., from Lake Baikal, has large open fls., a diffuse habit and a lax arrangement of the whorls of fls.

Hyssop is a hardy perennial subshrub, 18 inches tall. The whole plant has a strong odor and pungent, bitter taste. The green parts are used in connection with wormwood and other plants in the manufacture of absinthe, occasionally as a pot-herb, and as a flavoring for cold-salad plants. The powdered, dried flowers are similarly employed in soups. The flower-spikes are cut just as the blossoms begin to open, and are dried for use in domestic medicine as a stimulant and expectorant in the treatment of asthma, coughs and other pulmonary troubles. Hyssop is not now so highly esteemed as formerly by the medical profession.

This plant is readily propagated by seeds, cuttings and plant-division. The seed, generally employed in cold climates, is sown in early spring, either in drills 15 to 18 inches apart where the plants are to remain, or broadcast in nursery beds for transplanting, 12 inches apart in June or July. Propagation by cuttings and by divisions may be done in the autumn, but better in the spring, when the plants first start to grow. Greenwood cuttings may be started in the shade in the early summer. They need to be well watered. The soil should be a light, mellow, calcareous or sandy loam, with a warm aspect. Culture and harvesting are the same as for sage, mint and other herbs. The beds should be renewed every three or four years. M. G. Kains.

HÝSTRIX (Greek, from *hustrix,* a porcupine). *Gramíneæ.* Perennials with simple culms, flat blades and loosely fld. spikes: spikelets 2–4-fld., nearly sessile, 1–3 together at each joint of a zigzag rachis as in Elymus, widely divergent at maturity; glumes 1 or 2 short awns; lemmas rigid, tapering into a long awn.—Species 4, N. Amer. and Eurasia. *H. pátula,* Moench (*Asprélla Hýstrix,* Willd.), Bottle-brush Grass is found in E. U. S. and is sometimes used for lawn decoration and for borders. Dept. Agric., Div. Agrost. 20:168.

A. S. Hitchcock.



1943. Hyssop.—Hyssopus officinalis. (×½)

I

IBÈRIS (from *Iberia*, the ancient name of Spain, where many species occur). *Cruciferæ.* Candytuft. Small flower-garden and border plants.

Annual, biennial or perennial, sometimes half-shrubby, usually glabrous but sometimes ciliate or even hairy: lvs. alternate, entire or pinnatifid, sometimes fleshy: fls. racemose or corymbose, white or purplish, the outer ones in the dense cluster more or less radiate; sepals 4, deciduous; petals 4, the 2 outer much larger than the others; stamens 4, free, not appendaged: fr. a scale-shaped roundish or ovate pod which is margined or winged and often notched at the top, plano-compressed; seeds single in each locule, ovate, not margined.—Species 30–40, native to S. Eu., W. Asia and N. Afr., all low-growing plants. Comparatively few species are cult. The annuals are the common candytuft of gardens. The biennials are not cult. The subshrubs are flat, dwarf, compact, commonly evergreen plants, with dark green lvs., completely covered with broad, flat or elongated clusters of irregular cruciferous fls. in spring. The common white-fld. annual candytuft is *I. amara.* The common annual kinds with colored fls. are *I. umbellata.* The common perennial kind is *I. sempervirens.* The clusters of some kinds remain rather flat-topped when they run to seed, while the clusters of other kinds lengthen after flowering; these differences are made division points in the arrangement of species, following.

1944. Iberis gibraltarica. (×½)

The annuals are showy branching plants, 6 to 18 inches high, much grown in masses in beds or for edging. Florists grow them also, especially the white varieties, for cut-flowers. They are of easy cultivation, and succeed in any rich garden soil, in a place exposed to light and air. They are propagated by seeds, which may be sown at any season, in the house or open ground, but particularly in the fall when the climate permits, or as early as possible in spring, in rows 6 to 8 inches apart where the plants are to grow, the plants being thinned later to 4 inches apart in the row. The finest display is attained from autumn-sown plants, which flower from May to July. If seed is sown in autumn, the plants should be slightly protected from the sun during winter. Seeds sown early in the spring bloom from July to September. Continuous bloom may be obtained by sowing every two weeks. Good results are attained by sowing under glass and transplanting into open ground when the soil is warm. To secure the best bloom, the plants should be given much room, and never crowded. The name candytuft was given because the flowers appear in tufts and because the first introduced species, *I. umbellata,* was brought from Candia.—The subshrubby species are adapted to the front of shrubberies, where they connect taller plants with the surrounding lawn. They may appear in separate clumps, in broad masses, or may mingle with other genera in the herbaceous border. They are suited to rockeries, and hang well over walls and ledges. They are to be treated much like herbaceous perennials. They are plants of refinement, and are pleasing when close to the observer. They are useful and popular for cut-flowers, are easily forced into bloom in winter, and are adapted to pot and pan culture. They are easily propagated. The perennial iberis succeed best when let alone. Once planted and not disturbed, they soon form a dense foliage. They are the best spreading, dwarf plants with white flowers. (A. Phelps Wyman.)

A. *Infl. racemose in fr.*

B. *Annuals or biennials: sts. not woody at the base.*

C. *Lobes of the pod erect.*

1. **amàra,** Linn. Common Annual Candytuft. Plant erect, stiffish, 6–12 in., very bitter: lvs. lanceolate, toothed toward apex: fls. white, the clusters at first short but afterward elongating: pod nearly orbicular. Common weed of cult. ground in Great Britain and Cent. and S. Eu. The best form is var. **coronària,** Voss (*I. coronària,* Hort., not D. Don). Rocket Candytuft. This has larger and fuller clusters and larger fls. The taller varieties, Empress, Spiral White, and Giant Snowflake, grow 18 in. high, with solid pyramidal trusses 5–8 in. long. Dwarf forms are Tom Thumb and Little Prince. All are good bedders, and Empress is excellent for cutting. Seed may be sown at any time, but the best results with Empress are secured by sowing under glass and transplanting to the open, where plants will bloom in May and June.

2. **pectinàta,** Boiss. (*I. affinis,* Hort., not Jord.). Lvs. pectinate (i.e., divisions deeper, narrower, and farther apart): fls. white. Spain.—Advertised only as *A. affinis.* Likely to be confused with *I. odorata,* but the petals are 4 times as long as the calyx and the pods have short hairs, while in *I. odorata* the petals are 1½ times as long as the calyx and the pods glabrous.

CC. *Lobes of the pod spreading.*

3. **odoràta,** Linn. Sweet-scented or Fragrant Candytuft. Annual, 6–12 in.: lvs. linear, wider toward the top, toothed, ciliate toward base: fls. white, fragrant. Greece, Syria.—Frequently confused with *I. pinnata.* Said to be better and more fragrant in poor soil.

4. **pinnàta,** Linn. Annual or biennial, with oblong-linear pinnatifid or pinnatisect lvs., the segms. being very narrow: 12 in. or less: fls. white, fragrant; infl. only slightly elongated in fr. and therefore sometimes described as corymbose. Spain, S. France, Italy.—Said to be often sold as *I. odorata.*

BB. *Perennials: sts. woody at the base.*

C. *While in flower, racemose.*

5. **sempérvirens,** Linn. Perennial, to 1 ft., branching, somewhat shrubby: lvs. oblong, obtuse, narrowed at base, glabrous: fls. white, in elongating racemes. S. Eu. Gng. 2:145 (fine habit sketch). F.R. 1:75 (poor). G.W. 8, p. 373. Var. **plèna,** a double form, is cult., but is less desirable. Var. **ròsea** and var. **fòliis variegàtis,** are sold abroad. Var. **supérba,** or Perfection, is said to be one of the best forms.—This is the commonest, hardiest and most permanent of the perennial kinds. When the rarer and tenderer kinds are winter-killed, *I. sempervirens* is likely to spread out and surround the labels of other kinds. This probably explains why some of the most reliable dealers have sold this plant under other names, particularly *I. gibraltarica.*

CC. *While in flower, corymbose.*

D. *Margin of lvs. entire.*

6. **saxátilis,** Linn. Perennial, dwarf, evergreen, 6 in. or less, with ascending sts.: lvs. linear, entire and somewhat fleshy, mostly ciliate: fls. white, corymbose. S. Eu. Var. **corifòlia,** Sims (*I. corifòlia,* Sweet). Lvs. glabrous: fls. white. B.M. 1642, although this picture was doubtfully referred by Baker to *I. Garrexiana.* G.M. 46:289.

1945. Iberis Tenoreana var. petræa.

7. **Garrexiàna,** All., not Scop. Lvs. oblong, narrow at the base, glabrous: fls. rather small, white, the racemes much elongating. Piedmont, Pyrenees. Referred by some to *I. sempervirens.* Intermediate between *I. sempervirens* and *I. saxatilis,* having the habit of the latter. It is sometimes described as *I. sempervirens* var. *Garrexiana.* Gn. 62, p. 393. G.M. 48:211.

DD. *Margin of lvs. toothed toward apex.*

8. **gibraltárica,** Linn. Fig. 1944. Perennial, evergreen, diffuse, 12–20 in.: lvs. wedge-shaped, obtuse, subciliate: outer fls. pink, inner ones white. Spain, Morocco. B.M. 124. G.C. III. 46:158. Gn. 10:288; 76, p. 69. G. 27:446. R.H. 1870:330. Gn. 24, p. 549, same as R. H. 1885, p. 446.—This is considered by some as the most striking and showy of the perennial kinds. It grows higher and more erect, with larger clusters and larger fls., but is less hardy than the others. This is much sought after, and the stock in the nurseries is often not true to name. Var. **hýbrida,** is advertised, the fls. white shading to lilac.

AA. *Infl. corymbose in fr.*

B. *Annuals: sts. not woody at the base.*

9. **umbellàta,** Linn. COMMON ANNUAL CANDYTUFT. Upright, 6–15 in.: lvs. lanceolate, acuminate, lower ones serrate, upper ones entire: fls. in the wild typically purplish, rarely white, in umbels terminating all the main sts.: pods acutely 2-lobed. Italy, Crete, Spain. B.M. 106.—This is the common hardy annual candytuft with colored fls., the colors being more numerous and better fixed than in any other species. Trade names are vars. **carmínea, cárnea, lilácina** and **Dúnnettii** (*I. Dúnnettii,* Hort.), the last being dark purple. Vars. **ròsea, purpùrea** and **álba** are advertised abroad, also vars. **nàna, pùmila** and **hýbrida.** Tall and dwarf forms of all the colors are procurable.

BB. *Perennials: sts. woody at the base.*

C. *Lvs. ciliate, crenate.*

10. **Tenoreàna,** DC. Perennial, somewhat shrubby at base, ascending, about 6 in. high: lower lvs. obovate, narrowed at base; upper lvs. oblong-linear: fls. purplish or whitish, the clusters flattish and not elongating: pods notched at apex. Naples. B.M. 2783. L.B.C. 18:1721. G. 34:119.—According to Baker (G.C. 1868: 711), this is the only perennial kind that is decidedly hairy. DeCandolle says the lvs. are puberulous. Var. **petræa,** Nichols. (*I. petræa,* Jord.). Fig. 1945. A good rock-garden form, with fls. white tinged red in center.

CC. *Lvs. not ciliate, entire or subdentate.*

11. **Prùitii,** Tineo. Perennial, 6 in., woody at base: lvs. glabrous, obovate-spatulate, entire or subdentate: fls. white, in compact clusters: pods merely notched at apex; seed not margined, the radicle descending; septum of pod simple. Sicily.

12. **semperflòrens,** Linn. Perennial, evergreen, 1–2 ft.: lvs. wedge-shaped or spatulate, obtuse, entire, glabrous, somewhat fleshy: fls. large, pure white, fragrant: pods scarcely notched at apex; seed somewhat margined, the radicle horizontal; septum of pod nearly double. Sicily and perhaps Persia. Var. **plèna,** a double variety. Var. **fòliis variegàtis** said to be cult. abroad.

I. cordifòlia is an error for I. corifolia.—*I. correæfòlia,* Hort., is a common trade name abroad, which is usually spelled, I. corræfolia in American catalogues. There is no genus Corra, and Correa is an Australian plant of the Rutaceæ. Specimens should therefore be compared with I. saxatilis var. corifolia. Mottet's description, however, would place this plant directly after I. Garrexiana in the key, being distinguished from I. Garrexiana by the fls. becoming purplish instead of always remaining white. Mottet says that I. correæfolia, Hort., is a hybrid, with spatulate, entire, obtuse lvs.—*I hyacinthiflòra,* Hort., is an annual candytuft with milk-white fls. in elongated panicles. It is said to be a first-quality cut-fl. for summer bloom.—*I. jucúnda,* Schott & Kotschy=Æthionema coridifolium.—*I. Lagascàna,* DC. Annual, 1 ft.: lvs. oblong-spatulate, toothed at apex: fls. pure white, in close corymbs: pods 2-lobed. Spain.—*I. lilácina* of trade catalogues is presumably a lilac-fld. variety of I. umbellata.—*I. nàna hýbrida,* Hort., is not I. nana, All., a distinct botanical species, but a trade name of mixed dwarf varieties of some common annual kind, presumably I. umbellata.

WILHELM MILLER.
L. H. B.†

IBÍDIUM (named from the fancied resemblance of the anther to the beak of an ibis). *Orchidàceæ.* By some authors used to supplant the generic name Spiranthes (which see), but the latter name is retained by the "nomina conservanda" of the Vienna code. Under Ibidium, the nomenclature becomes:

I. coloratum, House (*Spiranthes colorata,* N.E. Br.);

I. cernuum, House (*Spiranthes cernua,* Rich.);

I. Romanzoffianum, House (*Spiranthes Romanzoffiana,* Cham.);

I. plantagineum, House (*Neottia plantaginea,* Raf. *Neottia lucida,* H. H. Eaton. *Spiranthes latifolia,* Torr. *S. lucida,* Ames);

I. præcox, House (*Spiranthes præcox,* Wats.);

I. Beckii, House (*Spiranthes Beckii,* Lindl. *S. simplex,* Gray. *S. Grayi,* Ames);

I. gracile, House (*Neottia gracilis,* Bigel. *Spiranthes gracilis,* Beck);

I. vernale, House (*Spiranthes vernalis,* Engelm. & Gray). Lvs. oblong-lanceolate to linear-lanceolate, tapering to both ends, ¼in. wide or less, mostly basal, the lower ones usually withering before flowering time: scape densely pubescent above; floral-bracts longer than the ovaries, with hyaline margins; raceme slender, 1-ranked, 1–3 in. long; fls. ⅓in. long, yellowish, lip ovate to ovate-oblong, pubescent beneath. Mass. to Fla., Ill. and Kans.

H. D. HOUSE.

ICACÒREA: *Ardisia.*

IDÈSIA (Yobrants Ides, Dutch traveler in China). *Flacourtiàceæ.* Ornamental tree grown for its handsome large foliage and also for the attractive orange-red berries.

Deciduous: lvs. alternate, long-petioled, 3–5-nerved at the base, crenate-serrate; stipules small, caducous: fls. diœcious, in large terminal panicles; sepals 5 (3–6); petals wanting; stamens, numerous, with villous filaments; ovary 1-celled, with 3–6 spreading styles: fr. a many-seeded berry.—One species in S. Japan and Cent. and W. China.

This is a handsome tree with close grayish white bark and spreading branches forming a low broad head; the rather large lustrous leaves are borne on long reddish stalks; the flowers are not showy, but the orange-red berries, borne in pendulous racemes sometimes 10 inches long, are very conspicuous, particularly after the leaves have fallen. The plants raised from seeds recently introduced from Central China have proved hardy at the Arnold Arboretum, at least in favorable positions, while the Japanese plant introduced about fifty years ago is not hardy north of Philadelphia; otherwise there is no difference between the Japanese and the Chinese plant. The tree grows quite rapidly while young and does not seem particular as to the soil. Propagation is by seeds, which germinate readily, and by greenwood and root-cuttings.

polycárpa, Maxim. (*Polycárpa Maximowiczii,* Hort.). Tree, to 50 ft.: lvs. usually cordate-ovate, rarely oblong-ovate, acuminate, remotely crenate-serrate, deep green above, glaucous below, glabrous, 5–10 in. long; petiole 4–6 in. long: fls. greenish yellow, fragrant, in pendulous panicles 4–10 in. long; staminate fls. over ½in. across, pistillate ⅓in. June; fr. in Sept.–Nov. B.M. 6794. Gn. 12, p. 532; 13, p. 99. R.H. 1872, pp. 174, 175; 1888, pp. 463–5. F. 1874, pp. 64, 65. F.S.R. 2, p. 189. J.H.S. 27:410. L.I. 11. S.I.F. 1:76. Gt. 39, p. 40 (habit). F.E. 24:853. G.C. III. 39:13. Var. **vestita,** Diels. Lvs. densely pubescent or tomentose below. W. China. Tender. Var. **críspa,** Carr. Lvs. irregularly incised and curled. R.H. 1878, p. 254; 1888, p. 463. Gn. 15, p. 471. Var. **fòliis variegàtis,** Hort. Lvs. variegated with sulfur-yellow and gray.

Alfred Rehder.

ÌLEX (the ancient Latin name of *Quercus Ilex*). Including *Prìnos* and *Othèra. Aquifoliàceæ* (or *Ilicìneæ*). Holly. Ornamental woody plants, grown for their handsome foliage and the attractive mostly red berries.

Evergreen or deciduous trees or shrubs: lvs. alternate, petioled, with small, caducous stipules, sometimes spiny: fls. diœcious, usually in rather few-fld. axillary cymes; calyx-lobes, petals and stamens usually 4, sometimes more; ovary superior; style very short: fr. a berry-like drupe, with 2–8 bony 1-seeded stones.—About 275 species in N. and S. Amer., Trop. and Temp. Asia, and few in Afr., Austral. and Eu. Monograph by Loesener in Nov. Act. Leop.-Carol. Acad. 71, pt. 1 (1901). For a horticultural monograph, see Dallimore, Holly, Yew and Box, pp. 1–149 (1909), with many illustrations.

The hollies have medium-sized, simple leaves, small, inconspicuous, whitish flowers in axillary clusters or solitary, and black, red or sometimes yellow berries, remaining on the branches often until the following spring. Of the evergreen species, only *I. glabra* and *I. opaca* are hardy North, and also *I. crenata* in somewhat sheltered positions. *I. Aquifolium, I. Pernyi,* and *I. cornuta* are more tender, but stand many degrees of frost if sheltered, while most of the others can be grown only in the South. Of the deciduous species, *I. decidua, I. monticola, I. lævigata* and *I. verticillata* are hardy North; also *I. serrata* and some other Japanese species are hardy or nearly so. The hollies, especially those with scarlet or red berries, are highly ornamental, and the berried branches of *I. opaca* and *I. Aquifolium* are in great demand for Christmas decoration. Also *I. lævigata* and *I. verticillata,* the prettiest in fruit of the deciduous kinds, are sometimes sold for this purpose. The deciduous species are mostly shrubs, while many of the evergreen species grow into small or medium-sized trees, and *I. opaca* is the tallest of the broad-leaved evergreens which are hardy North and thrives even on extremely poor soil, and has good color also; the evergreens *I. crenata,* and *I. glabra* always remain shrubby. *I. Aquifolium* is a favorite evergreen in English gardens, and numerous varieties are there in cultivation; it also grows well on the Pacific coast from British Columbia to California. It stands severe pruning well, and can be clipped and trained into almost every shape; it also makes fine hedges, but its slow growth is a disadvantage. As the chief value of the deciduous species is in the ornamental fruits, and the hollies are diœcious, care should be taken to choose in planting mostly pistillate plants and a few staminate ones and to give the former the most prominent place. The light, close-grained and tough wood of some of the arborescent species is much valued for turnery-work, engraving and cabinent-making. The leaves of some tropical species, as *I. paraguariensis* and *I. conocarpa,* yield a kind of tea known as Yerba de Maté, or Paraguay tea, which is much used in South America.

The hollies grow best in rich, well-drained soil, and the evergreen ones in partly shaded situations, but *I. lævigata, I. verticillata* and also *I. serrata* prefer moist places, and grow even in swamps. Most of the species grow slowly, and are not easily transplanted when older. The best time for moving the evergreen species is the early fall, when the young wood has almost ripened, or in the spring just before the plants start into new growth. The leaves should be stripped on *I. opaca* and *I. Aquifolium* when transplanted, particularly if at all exposed—or at least nearly all. This is absolutely necessary to insure success. Wild hollies may be handled this way with success, particularly if cut back as well. Propagation is by seeds, which do not germinate until the second year, and are therefore stratified and treated like those of the slow-growing hawthorns. The young seedlings should be transplanted after the second year. The evergreen species may be increased by cuttings of ripened wood under glass, especially the shrubby ones; they are also sometimes grafted or budded on seedlings of *I. Aquifolium* or *I. opaca.*

A. *Foliage evergreen (Nos. 1–47).*

B. *Lvs. with coarse, spiny teeth, rarely entire.*

C. *Fls. in axillary clusters on branches of the previous year.*

D. *Frs. and fls. stalked.*

E. *Shape of lvs. oval or ovate to lanceolate.*

1. **Aquifòlium,** Linn. English Holly. Fig. 1946. Tree, to 40 ft., with short, spreading branches, forming an oblong or pyramidal head, in cult. often shrubby, glabrous: lvs. short-petioled, usually ovate or oblong-ovate, waved and with strong, spiny teeth, shining, 1½–3 in. long: fr. scarlet, globular, shining. May, June. S. and Cent. Eu., W. Asia, China. Gng. 4:83. H.W. 3, p. 51.—A very variable species. A full account of the numerous varieties cult. in England is given by T. Moore in G.C. II. 2, pp. 432, 519, 687, 750, 812; 4, pp. 687, 741; 5, pp. 43, 365, 437, 624; 6, pp. 232, 389, 616, where 153 varieties are described and many of them figured. Some of the most important and most distinct are described below. *Osmanthus Aquifolium,* Sieb. & Zucc., an oleaceous shrub, which may readily be known by its opposite lvs., is occasionally supplied by dealers as a variety of *Ilex Aquifolium.*

1946. Ilex Aquifolium. (×⅓)

(a) *Varieties with foliage green.*

(b) *Lvs. spiny-toothed.*

(c) *Size of lvs. large, about 2–4 in. long.*

2. Var. **alteclarénsis,** Loud. Lvs. oval, large, thin and rather plain, with numerous teeth. G.C. III. 34:322. G.M. 54:321. 3. Var. **Hódginsonii,** Waterer. Lvs. roundish ovate, dark green, 2¾–3¾ in. long, with distant and nearly equal spines. G.C. III. 34:322. 4. Var. **latifòlia,** Loud. Lvs. oval, to 3½ in. long, with rather few, divaricate teeth. G.C. II. 2:433. 5. Var. **platyphýllos,** Goepp. Lvs. broadly ovate, to 3½ in. long, with divaricate spines, thick, deep green. 6. Var. **prínceps,** Moore. Lvs. broadly ovate, to 4½ in. long, with strong, regular spines, dark green, with prominent veins below. G.C. II. 13:45. 7. Var. **Wílsonii,** Hort. Lvs. oval, with numerous well-developed spines in the same plane, dark green, with distinct veins, up to 5 in. long: fr. large. G.C. III. 30:117. Gn. 69:205. In this group belong also, var. *conspícua,* Moore (G.C. II. 13:45); var. *Múndyi,* Hort. (Gn. 65, p. 394); var. *nóbilis,* Lawson (G.C. II. 2:432. Gn. 63, p. 423); var. *Shépherdii,* Waterer (Gn. 65, p. 394).—The varieties of this group are probably mostly hybrids between *I. Aquifolium* and *I. perado.* A geographical variety is 8, var. **chinénsis,** Loes. Lvs. ovate-oblong to oblong-lanceolate, spiny-dentate: fls. smaller. Cent. China.

(cc) *Size of lvs. small, 1–2 in. long.*

9. Var. **handsworthénsis,** Fisher. Lvs. ovate-lanceolate, with numerous, moderately divaricate spines, projected toward the apex, glossy green. G.C. II. 2:519; III. 30:118, 131. 10. Var. **hastàta,** Smith. Lvs. ovate-lanceolate, halbert-shaped; spines large, usually only 2–4 on each side at the base, the upper half usually entire. G.C. II. 2:687. 11. Var. **microphýlla,** Fisher. Lvs. ovate-lanceolate, about 1 in. long, shining green, with small, equal plane spines. G.C. II. 2:751. A very small-lvd. form, but var. **lineàta,** Waterer, is still smaller, and has the smallest lvs. of all. 12. Var. **myrtifòlia,** Waterer. Lvs. ovate-lanceolate, 1–1½ in. long, moderately spiny, rarely entire. G.C. II. 2:687. G.M. 31:652. 13. Var. **serratifòlia,** Loud. Lvs. ovate-lanceolate, stiff, with numerous small spiny teeth. G.C. II. 2:687. 14. Var. **fèrox,** Ait. (*I. echinàta,* Mill.). Lvs. of medium size, with strong teeth and numerous small spines on the upper convex surface. A very distinct variety, known as hedgehog holly.

(bb) *Lvs. all or most of them without spines.*

15. Var. **heterophýlla,** Ait. Lvs. oval or elliptic-ovate, about 2½ in. long, sometimes twisted near the apex, entire or with few spiny teeth. G.C. II. 2:519. 16. Var. **laurifòlia,** Loud. Lvs. ovate to elliptic-lanceolate, 2–3 in. long, usually quite entire. G.C. III. 34:314. Gn. 63, pp. 378, 423, 424. 17. Var. **marginàta,** Loud. Lvs. broadly ovate, sometimes twisted near the apex, with thickened entire margin. G.C. II. 2:813. 18. Var. **scótica,** Hort. Lvs. oval-obovate, blunt and rounded at the apex, rarely pointed, 1½–2 in. long, with thickened, wavy entire margin. G.C. II. 2:813. 19. Var. **recúrva,** Loud. (var. *críspa,* Lawson; var. *tortuòsa,* Waterer). Lvs. oval and spirally twisted, with revolute margin, entire or with few spines, about 2 in. long: of dense habit. G.M. 31:654; 36:764. G.C. II. 2:813. 20. Var. **camelliæfòlia,** Fisher (var. *magnífica,* Hort.; var. *laurifòlia longifòlia,* Hort.). Lvs. elliptic or oblong, acuminate, dark olive-green, very glossy, entire or with a few spines near the apex. G.C. II. 2:813. Gn. 65, p. 220. G.M. 31:783. Gt. 55:1551, 4.

(aa) *Varieties with foliage variegated.*

(b) *Lvs. spiny-toothed.*

21. Var. **álbo-marginàta,** Loud. (var. *argénteo-marginàta,* Hort.; var. *argéntea,* Hort.). Lvs. broadly ovate, to 2½ in. long, with numerous irregular spines, dark green, the disk mottled with grayish green, with rather narrow silvery margin. Gn. 64, p. 301. G.M. 48:84. 22. Var. **álbo-pícta,** Loud. (var. *argénteo-mèdio-pícta,* Hort.). Lvs. ovate, with divaricate spines, dark green, with a whitish center and a narrow, irregular, silvery margin. G.C. II. 4:687. 23. Var. **aùreo-maculàta,** Hort. Lvs. oblong-oval, 2½ in. long, with distant triangular, somewhat divaricate spines, with a large creamy-white blotch in the center, outer part of the margin dark green, inner part mottled pale gray. G.M. 31:654. 24. Var. **aùreo-regìna,** Hort. (var. *aùrea-marginàta* and var. *latifòlia marginàta,* Hort.). Lvs. broadly ovate, to 3 in. long, with strongly divaricate spines, mottled with gray and green, with a broad, continuous golden yellow margin. G.C. II. 5:44. G.M. 54:322. 25. Var. **aùreo-pícta latifòlia,** Hort. Lvs. ovate or broadly ovate, 2 in. or more long, with a large, branching, deep yellow blotch in the middle, and with an irregular, deep glossy green margin. G.C. II. 5:624. 26. Var. **fèrox argéntea,** Loud. Like var. *ferox,* but the margin and the surface spines creamy white. G.C. II. 5:44. 27. Var. **fèrox aùrea,** Loud., is like the former, but with yellow spines and margin. G. C. II. 6:616.

(bb) *Lvs. spineless or mostly so.*

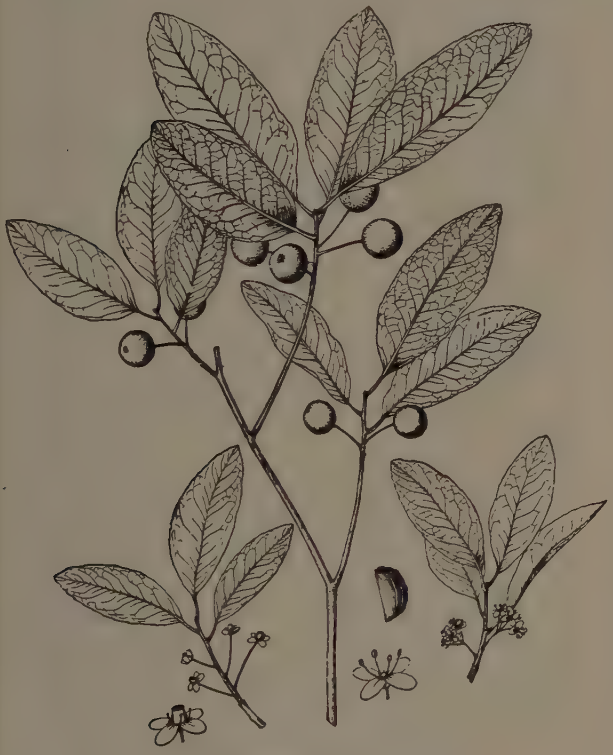
28. Var. **heterophýlla aùreo-pícta,** Hort. Lvs. ovate, flat, sometimes with few spines, about 2½ in. long, marked in the middle with a broad feathery blotch of bright yellow. G.C. II. 6:389. 29. Var. **scótica aùrea,** Hort. Lvs. obovate, blunt, slightly wavy, about 1½in. long, dark, mottled green, with a broad golden margin: of dwarf habit. 30. Var. **Wateriàna,** Hort. Lvs. oblong or ovate, with a few spines, or entire and plain and obtuse, about 2 in. long, mottled with gray and yellowish green and edged with a broad, irregular golden band. G.C. II. 6:233.

1947. Ilex opaca. (×⅓)

There are also some other varieties in cultivation, as 31, var. **frùctu lùteo,** Lawson, with yellow, and 32, var. **frùctu aurantìaco,** Paul, with orange berries; 33, var. **péndula,** Waterer, with pendulous branches (Gn.

62, p. 129. G.M. 48:81); and 34, var. **pyramidàlis,** Hort., with ascending branches, forming a narrow, oblong head.

35. **peràdo,** Ait. (*I. maderénsis,* Lam.). Shrub or tree, to 20 ft.: lvs. ovate, obovate or oval to oblong-lanceolate, spiny-dentate, or dentate-serrate with short spines, sometimes entire, spiny-pointed, or sometimes obtuse or even emarginate, glossy above, reticulate below, 2–4 or sometimes to 6 in. long, the blade decurrent into the margined petiole deeply channelled above: fr. dark red or nearly black, ½in. across. Madera, Canary Isls., and Azores. L.B.C. 6:549. B.M. 4079. G.C. III. 34:317. Gn. 69:205. G.M. 48:150. Var. **platyphýlla,** Loes. (*I. platyphýlla,* Webb. & Berth.). Lvs. ovate, rarely oblong, 4–8 in. long, in the staminate plant smaller, entire or spiny dentate-serrate with irregular short teeth. Var. **variegàta,** Hort. (*I. maderénsis variegàta,* Hort.). Lvs. 2½–3 in. long, with rather evenly arranged spiny teeth, with a golden blotch mixed with pale green in the center.



1948. Ilex Amelanchier (×½). No. 50.

EE. *Shape of lvs. quadrangular-oblong, 3-pointed at the apex.*

36. **cornùta,** Lindl. Shrubby, with short spreading branches, glabrous: lvs. quadrangular-oblong, with 3 strong spines of nearly equal size at the dilated apex, and with 1–2 strong spines on each side of the truncate base, but rounded and spineless at the base on older plants, dark glossy green above, 1½–3 in. long: fr. scarlet, clustered, short-pedicelled. June, July. N. China. G.C. 1850:311. F.S. 7, p. 216; 9:895. B.M. 5059. I.H. 1:10.

DD. *Frs. and fls. sessile or nearly so.*

37. **Pérnyi,** Franch. Shrub, to 10 ft.: branchlets densely and minutely pubescent: lvs. crowded, short-petioled, rhombic- or quadrangular-ovate, with 1–3 rigid spines on each side, the upper pair the largest, but shorter than the terminal spiny point, dark green and lustrous above, ¾–1 in. long: fls. in dense sessile clusters: fr. bright red, about ⅓in. across. May; fr. in Aug. Cent. China. H.I. 16:1539. G.C. III. 45:75. J.H.S. 34:220 (fig. 110). G.M. 51:714. R.B. 35:24. M.D.G. 1909:145.—A handsome evergreen of very compact habit. Var. **Veìtchii,** Rehd. (*I. Veìtchii,* Veitch). Lvs. truncate at the base, larger, 1½–2 in. long, with 4–5 rigid spines on each side.

38. **dipyrèna,** Wall. Tree, to 40 ft.: branchlets glabrous: lvs. short-petioled, elliptic-ovate to ovate-oblong, broadly cuneate or nearly rounded at the base, short and spiny-acuminate, remotely spiny-serrate with flat, not wavy margin, rarely entire, dark green and lustrous above, pale below, 2–4 in. long; petiole about ⅙in. long: fls. in axillary dense clusters, nearly sessile: fr. ovoid, red, lustrous, nearly ⅓in. long, with usually 2 stones. Himalayas. G.M. 54:339. Var. **paucispinòsa,** Loes. Lvs. oval to ovate-oblong, with 3–5 spreading strong spines on each side. Cent. China.

CC. *Fls. in 1- to few-fld. axillary, solitary cymes, on this year's growth.*

39. **opàca,** Ait. (*I. quercifòlia,* Meerb.). American Holly. Fig. 1947. Tree, with spreading short branches, sometimes to 50 ft., forming a narrow, pyramidal head, glabrous: lvs. oval or elliptic-lanceolate, with large remote spiny teeth, rarely entire, dull green above, yellowish green beneath, 2–4 in. long: fr. dull scarlet, usually solitary, globose. June. Mass. to Fla., west to Mo. and Texas. Em. 385. S.S. 1:45. Gng. 4:276, 277. F.E. 16:444, pl. 63; 20:402, pl. 14. Gn.M. 2:19; 4:237. V. 3:86; 12:79, 80.—Hardier than *I. Aquifolium,* but less handsome. Var. **xanthocárpa,** Rehd. Frs. yellow.

BB. *Lvs. serrate, crenate or entire.*

C. *Fr. red or yellow; nutlet ribbed on the back. Tender.*

D. *Margin of lvs. entire.*

40. **ìntegra,** Thunb. (*Othèra japónica,* Thunb. *Ilex Othèra,* Spreng.). Evergreen shrub or tree, to 40 ft., glabrous: lvs. slender-petioled, oval to elliptic-oblong or oblong-obovate, rarely oblanceolate, narrowed at the base, at the apex contracted into a short obtuse point, entire, very rarely with a few teeth, indistinctly veined, 2–3½ in. long; petiole ⅓–¾in. long: fls. on stalks ⅕–⅓in. long, in axillary fascicles on branches of the previous year: fr. red, globose or ovoid, ⅓–½in. long. Feb.–April; fr. in Aug.–Oct. Japan. S.I.F. 1:60. —Variable in the size and shape of the lvs. and in the length of the pedicels; one of the forms is cult. in the S. as *Othera japonica.*

DD. *Margin of lvs. crenate or serrate.*

E. *Lvs. longer than 3 in.*

F. *Apex of lvs. acuminate or acute.*

41. **latifòlia,** Thunb. Tree, sometimes to 60 ft., glabrous: lvs. oval to oblong-lanceolate or obovate-oblong, acuminate, serrate, glossy green above, 3–7 in. long; petiole about ½in. long: fr. red, ⅓in. across, short-stalked, in dense clusters. June. Japan. B.M. 5597. S.I.F. 1:62.—One of the most beautiful hollies.

42. **Fárgesii,** Franch. Shrub, to 15 ft., glabrous: lvs. oblong-lanceolate to oblanceolate, narrowly cuneate at the base, long-acuminate, denticulate-serrate usually only above the middle, dull green above, 3–5 in. long; petiole slender, about ½in. long: fls. short-stalked in dense axillary clusters on branchlets of the previous year: berries red, ¼–⅓in. across, on stalks about ¼in. long. May, June: fr. in Sept. Cent. China. Var. **megalophýlla,** Loes. Lvs. to 6 in. long and 1½ in. broad.

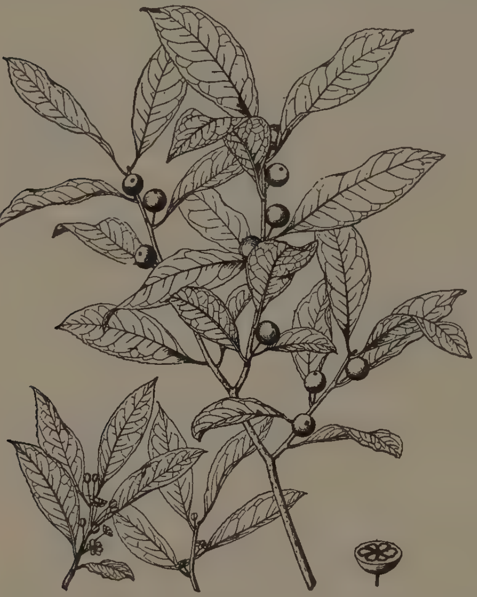
FF. *Apex of lvs. obtuse.*

43. **paraguariénsis,** St. Hil. (*I. paraguénsis,* Don). Shrub or small tree, to 20 ft.: branchlets glabrous or puberulous: lvs. obovate to obovate-oblong

or elliptic-oblong, narrowed at the base, obtuse or short and obtusely acuminate, crenate-serrate, glabrous or pubescent below, 3–5, rarely to 10 in. long: fls. axillary, fascicled or in stalked cymes: fr. globose or ovoid, ⅕–¼in. across, red or reddish brown. Brazil. B.M. 3992. J.F. 3, p. 69.

EE. *Lvs. shorter than 3 in.*

44. **Cassìne,** Linn. (*I. Dahoòn,* Walt.). DAHOON. Shrub or small tree, to 30 ft.: lvs. obovate to oblong-linear, acute or obtuse and mucronulate, entire or sharply serrate above the middle, usually pubescent beneath when young, 2–3 in. long: fr. globose, small, dull red, rarely yellow, on this year's growth. April, May. N. C. to Fla., west to La. S.S. 1:46. Var. **angustifòlia,** Ait. Lvs. linear-oblong to linear, 2–3 in. long. Var. **myrtifòlia,** Chapm. Lvs. linear-oblong, 1–2 in. long: fr. usually solitary. S.S. 1:45.—Cassine or cassena is the name in the language of the Timucua Indians for an exhilarating beverage prepared from the lvs. of the following plant which had been confused with this species; the name seems to have been borrowed from the Muscogee word *ássi,* leaves, modified by a prefix.



1949. Ilex lævigata (×½). No. 51.

45. **vomitòria,** Ait. (*I. Cassìne,* Walt., not Linn. *I. caroliniàna,* Loes.). CASSENA. YAUPON. Shrub, rarely tree, to 25 ft., with spreading branches: lvs. oval or oblong, obtuse, crenate, glabrous, ½–1, rarely to 2 in. long: fls. clustered on branches of the previous year: fr. scarlet, globose, small. April. Va. to Fla., west to Ark. and Texas. S.S. 1:48. C.L.A. 13:498.

CC. *Fr. black; nutlets smooth: pistillate fls. usually solitary, on this year's growth.*

46. **crenàta,** Thunb. (*I. Fórtunei,* Hort.). Much-branched shrub, rarely small tree to 20 ft.: lvs. oval, obovate or oblong-lanceolate, crenately serrate, glabrous, ½–1½ in. long: fls. 4-merous: fr. ¼in. across, solitary, short-stalked. May, June; fr. in Oct. Japan. Gng. 6:165. F.E. 30:1161. G.M. 46:208. Gn. 64, p. 413. Gn.M. 4:237. Var. **microphýlla,** Maxim. Lvs. ⅓–½in. long, elliptic or elliptic-oblong. This variety is somewhat hardier than the type. Var. **longifòlia,** Hort. Lvs. elliptic-oblong to lanceolate. Var. **lùteo-variegàta,** Regel (var. *aùreo-variegàta,* Hort.). Lvs. spotted yellow, obovate. M.D.G. 1913:53.

47. **glàbra,** Gray (*Prìnos glàber,* Linn.). INKBERRY. WINTERBERRY. Much-branched upright shrub, to 8 ft.: lvs. obovate to oblanceolate, obtuse, with few obtuse teeth toward the apex, glabrous, 1–2 in. long: fls. 5–8-merous. June. Mass. to Fla., west to Miss. L.B.C. 5:450.

AA. *Foliage deciduous: fr. red.* (*Prinos.*)

B. *Frs. mostly and lvs. partly fascicled on short spurs: nutlets ribbed on the back.*

48. **decídua,** Walt. (*Prìnos decíduus,* DC.). Shrub or small tree, to 30 ft., with light gray, spreading branches: lvs. cuneate-oblong or obovate, usually obtuse, crenately serrate, dark green, and with impressed veins above, pale and pubescent beneath, 1½–3 in. long: fr. globose, orange or orange-scarlet, ⅓in. across. May. Va. to Fla., west to Texas. S.S. 1:49. G.C. II. 14:689.

49. **montícola,** Gray (*I. dùbia,* Brit. Stern. & Pogg.). Tree, to 40 ft., with slender branches, forming a narrow pyramidal head or spreading shrub: lvs. oval or oval-lanceolate, acute or acuminate, sharply serrate, pubescent only along the veins beneath, 2–6 in. long: fr. red, globular-ovoid, over ⅓ in. across. May. N. Y. to S. C., west to Ala. S.S. 1:50. Var. **móllis,** Brit. (*I. móllis,* Gray). Lvs. broadly ovate, soft-pubescent when young, glabrous above at length. Var. **macrópoda,** Rehd. (*I. dùbia* var. *macrópoda,* Loes. *I. macrópoda,* Miq.). Lvs. ovate or oval, pubescent below. Japan, Cent. China. S.I.F. 1:59.

BB. *Frs. and lvs. not fascicled: frs. axillary.*

C. *Stalks of fr. ⅓in. long, nutlets ribbed on back.*

50. **Amelánchier,** Curtis. Fig. 1948. Deciduous shrub to 6 ft.: lvs. oblong, subacute, serrate, pubescent, 1½–3 in. long: staminate fls. several on a common peduncle: fr. dull red, large; nutlets strongly 3-ribbed on back. Va. to La. G.F. 2:41 (adapted in Fig. 1948).—Hardy.

CC. *Stalks of fr. ¼in. or shorter; nutlets smooth.*

D. *Fls. 6–9-merous.*

51. **lævigàta,** Gray (*Prìnos lævigàtus,* Pursh). WINTERBERRY. Fig. 1949. Low shrub, of upright habit: lvs. lanceolate, acute, finely or crenately serrate, rather thick, glabrous or nearly so, 1½–2½ in. long, turning clear yellow in fall: staminate fls. on long and slender stalks: fr. depressed-globose, bright orange-red, over ¼in. across. May, June; fr. in Sept. Maine to Pa. and Va. G.F. 4:221 (adapted in Fig. 1949). Gt. 55:1551, 3. Var. **Hérveyi,** Rob. Frs. bright yellow.

52. **verticillàta,** Gray (*Prìnos verticillàtus,* Linn.). BLACK ALDER. WINTERBERRY. Fig. 1950. Shrub, with spreading branches: lvs. obovate to oblanceolate or lanceolate, acuminate or acute, serrate or doubly serrate, usually pubescent beneath, 1½–3 in. long, turning black after frost: all fls. short-stalked: fr. bright red, about ¼in. across. June, July: fr. in Oct. Canada to Fla., west to Wis. and Mo. Em. 388. F.E. 24:779. Var. **tenuifòlia,** Torr. (*I. bronxénsis,* Brit.). Lvs. obovate, glabrous or pubescent, thin: fls. and frs. larger. B.B. (ed. 2) 3:489. Var. **chrysocàrpa,** Rob. Frs. bright yellow. Also *I. fastigiàta,* Bicknell, from Nantucket, differing in its fastigiate habit and in the narrower lanceolate or oblong-lanceolate lvs., is probably only a variety of this species.—Very variable in shape and texture of lvs. One of the best hardy shrubs with ornamental frs. remaining on the branches until midwinter, and are rarely eaten by birds.

DD. *Fls. 4–5-merous.*

53. **serràta,** Thunb. (*I. Siebóldii,* Miq.). Slender shrub, to 15 ft., similar to the former but smaller in every part: lvs. elliptic or ovate, acute or acuminate, finely serrate, pubescent beneath, 1–2 in. long: fls. 4–5-merous: fr. bright red, small ⅙–⅕in. across. June;

fr. in Oct. Japan. S.T.S. 1:15. S.I.F. 1:61. Var. **argùtidens,** Rehd. (*I. argùtidens*, Miq.). Lvs. glabrous beneath, short-petioled, teeth more remote and less fine: fls. usually 4-merous. Var. **xanthocárpa,** Hort. Frs. yellow.

I. ambígua, Chapm. Deciduous large shrub, allied to I. monticola. Lvs. usually almost glabrous, remotely serrate, 1–2 in. long. N. C. to Fla., west to Ark. and Texas.—*I. Brandegeeàna*, Loes. Evergreen tree to 40 ft.: branchlets pubescent: lvs. elliptic-lanceolate, remotely serrate or almost entire, pubescent, 2–3½ in. long: fls. 5-merous. Low. Calif. G.F. 7:416 (by error named I. californica.)—*I. califórnica*, Brandegee. Evergreen large shrub, to 12 ft., glabrous: lvs. elliptic to oblong-elliptic, obtuse, remotely and crenately serrulate, 2–5 in. long: fr. black, small. Low. Calif. G.F. 7:415 (by error named I. triflora).—*I. canariénsis*, Poir. Evergreen tree, to 20 ft., glabrous: lvs. ovate to ovate-oblong, obtuse, entire, 2–4 in. long: fr. usually solitary, on this year's growth. Canaries.—*I. conocárpa*, Reiss. Evergreen shrub, to 6 ft.: lvs. oblong-lanceolate, acuminate, serrulate, glabrous, 3–5 in. long: fls. in short, dense spikes: fr. ovoid-conic. Brazil. B.M. 7310.—*I. corállina*, Franch. Evergreen shrub: lvs. ovate-oblong, acuminate, spiny-serrate or nearly crenate-serrate, 2–3 in. long: frs. small, red, nearly sessile, in dense clusters. W. China.—*I. coriàcea*, Chapm. (I. lucida, Torr. & Gray). Allied to I. glabra, but taller: lvs. broader and longer, to 3 in., acute or acuminate. N. C. to Fla., west to La.—*I. Franchetiàna*, Loes. Evergreen shrub, to 12 ft., glabrous: lvs. elliptic-obovate to lanceolate-oblong or oblanceolate, acuminate, denticulate, 2½–4 in. long: fr. bright red on short stalks, in dense clusters. W. China. — *I. geniculàta*, Maxim. Deciduous shrub, glabrous: lvs. ovate to elliptic-ovate, acuminate, sharply serrate, 1½–2 in. long: fr. scarlet, solitary, drooping on filiform peduncles ¾–1½ in. long. Japan. Very graceful shrub; has proved hardy at the Arnold Arboretum.—*I. gongónha*, Mart.=Villaresia mucronata. — *I. insígnis*, Hook. f. Evergreen small tree: lvs. elliptic-lanceolate, 6–9 in. long, spiny-toothed, often almost entire on older plants: fr. large, globose. Himalayas. G. C. II. 14:297. G. M. 31:475.—*I. lóngipes*, Chapm. Deciduous shrub, allied to I. decidua: lvs. elliptic-lanceolate, crenately serrate, almost glabrous: fr. globose, slender-pedicelled. N. C. to Ga., west to La. G. F. 3:345.—*I. macrocárpa*, Oliver. Deciduous tree, to 30 ft., glabrous: lvs. elliptic or elliptic-ovate to oblong-lanceolate, finely serrate, 3–4½ in. long: frs. black, solitary, ½–¾in. across, on peduncles ½–1¼ in. long. Cent. China. H. I. 18:1787.—*I. microcárpa*, Lindl.=I. rotunda, Thunb.—*I. Óldhamii*, Miq.=I. purpurea, Thunb.—*I. pedunculòsa*, Miq. Evergreen small tree, glabrous: lvs. slender-petioled, elliptic-ovate to ovate-oblong, abruptly short-acuminate, entire or sparingly serrulate, 1½–3 in. long: fr. red, usually solitary on slender pedicels 1½–2 in. long. Japan. S. I. F. 1:61. Var. *continentàlis*, Loes. Lvs. generally larger, thicker: sepals ciliate. Cent. China.—*I. purpùrea*, Thunb. (I. Oldhamii, Miq.). Evergreen tree, glabrous: lvs. elliptic-ovate to oblong-lanceolate, crenate-serrulate, 2–3 in. long.: fr. red, ⅓in. across, pedicelled, usually 2–5 on a common peduncle about ⅓in. long. Japan, Cent. China. S. I. F. 1:62.—*I. rotúnda*, Thunb. (I. microcarpa, Lindl.). Evergreen shrub or tree, to 40 ft.: lvs. oblong or elliptic, acute, pointed, quite entire: fr. small, red, in peduncled clusters. Japan. G. C. 1850:311. F.S. 7, p. 216. S. I. F. 1:60.—*I. rugòsa*, F. Schmidt. Evergreen low spreading shrub, sometimes prostrate, glabrous: lvs. oblong-lanceolate to lanceolate, remotely crenate-serrate, rugose above, ¾–2 in. long: fr. usually solitary, scarlet. Japan, Saghalin. — *I. szechwanénsis*, Loes. Evergreen shrub, to 12 ft., glabrous: lvs. short-petioled, ovate- to elliptic-oblong, serrulate, 1–2½ in. long.: fr. black, solitary, on stalks about ¼in. long. Cent. China.—*I. triflòra*, Brandegee=I. Brandegeeana. —*I. yunnanénsis*, Franch. Evergreen shrub, to 10 ft.: branchlets villous: lvs. short-stalked, ovate to ovate-oblong, crenate-serrate or serrulate, pubescent below, at least on the midrib, ¾–1½ in. long: fr. red, solitary, stalked. W. China.

ALFRED REHDER.

ILLÍCIUM (Latin for *allurement;* probably in reference to the agreeable odor). *Magnoliàceæ.* Small trees or shrubs, one of which is sometimes planted far South.

Aromatic glabrous plants, with thick short-petioled entire evergreen lvs.: fls. perfect, small, solitary or in 3's in the axils of lvs. or bud-scales, nodding or inclined, yellow or purplish; sepals 3–6; petals many, imbricated in 3 or more rows or series; stamens 10 to many, with thick filaments: carpels usually many, forming a ring of almost woody pods.—Species about a score, mostly oriental (India, China, Philippines), and 2 in the S. U. S.

One of the illiciums furnishes the star or Chinese anise, which is the small star-shaped cluster of fruits. The odor and flavor strongly resemble anise. It is much used in oriental countries in cookery, and is exported to some extent and is said to be used in flavoring certain French wines. This product comes from China. It has been supposed to be the product of *I. anisatum* of Linnæus, but that plant is a Japanese tree and it contains a poison. In the American trade are the names *I. anisatum* and *I. religiosum.* It now transpires that these names belong to the same plant, and that the star anise is produced by another species. This other species, or the true star anise, was first accurately described and figured (as *I. verum*, Hook. f.) in B.M. 7005 (1888), where the confusion of two or three centuries is elucidated. There is probably only one east Asian illicium in the trade in North America, as follows:

anisàtum, Linn. (*I. religiòsum*, Sieb. & Zucc.). Small tree: lvs. alternate, elliptic, short-petioled, somewhat acuminate: fls. mostly solitary, sessile or nearly so, yellowish, not fragrant, with many very narrow petals, and 20–30 stamens. Japan. B.M. 3965.—Grown far S. About as hardy as camellia. There is a form with variegated lvs.

1950. Ilex verticillata (×½). No. 52.

Two native illiciums growing in the S. are: *I. floridànum*, Ellis. Shrub, 6–10 ft.: lvs. oblong-lanceolate, 4-in. or more long: petals 20–30, very narrow, dark crimson or purple. Fla. to La. B.M. 439. Gn. 36, p. 151. J.H. III. 30:365; 52:168. H.U. 5, p. 136.—*I. parviflòrum*, Michx. Lvs. elliptic or lanceolate, mostly under 4 in. long: petals very small (¼in. long), 6–12, yellowish: less tall. Ga. and Fla.—A species appearing in European horticultural literature in recent years is *I. laurifòlium*, Hort. It is described as a handsome evergreen shrub: lvs. short-stalked, oval, acute: fls. yellowish white, in many-fld. terminal cymes. Of uncertain origin. R.H. 1901, p. 17.—*I. vèrum*, Hook, f. The true star anise: 9 ft.: lvs. elliptic to oblanceolate: fls. red, globose, the petals about 10. China.

L. H. B.

IMANTOPHÝLLUM: *Clivia.*

IMBRICÀRIA: *Mimusops.*

IMMORTELLES: *Everlastings.*

IMPÀTIENS (from the Latin; having reference to the pods, which, when ripe, on slight pressure burst open, scattering the seed). *Balsaminàceæ.* TOUCH-ME-NOT. Flower-garden and greenhouse subjects, grown for the odd and ornamental blossoms.

Tender, succulent annual or perennial herbs, often with very fleshy sts. and simple lvs. usually alternate (sometimes opposite) and the upper ones often in whorls: peduncles axillary, with 1–6 or more very irregular fls. of various colors; sepals 3 (seldom 5), the posterior one taking on a spur-like shape, the 2 lateral ones short, green; petals 2 or 3, the one at the back commonly very broad and erect, sometimes keeled or winged, the lateral ones more or less 2-lobed or auricled; stamens 5, the filaments appendaged and the scales connivent over the stigma: fr. a 5-valved pod, which, when ripe, bursts when pinched, scattering the seeds.—Species probably 500, widely distributed about the world, largely in mountainous regions in warm-temperate and tropical countries. The genus has been greatly enlarged in recent years, with explorations in Afr. and other regions. It abounds in species that will probably have horticultural value, although relatively few are now in cult. outside botanical collections. The garden balsam (*I. Balsamina*) is a general favorite in the annual flower-garden. *I. Sultani* is common in greenhouses, and latterly *I. Holstii*, *I. Oliveri*, and a few others are sometimes seen. This beautiful genus has not been much developed horticulturally. Great numbers of species, hybrids and interesting forms may be expected to appear in cult. in the future. The genus has immense possibilities for productive horticultural work. The common touch-me-not of Great Britain and other parts of Eu. is *I. Noli-tangere* (sometimes written *I. Noli-me-tangere*), an erect smooth branching annual, 2 ft. or less high, with large showy yellow fls. spotted with orange, on slender axillary peduncles. It has been reported as an escape in N. Amer. The N. American *I. biflora* is naturalized in England.

The cultivation of impatiens is mostly simple and easy. The seeds are large and germinate readily (see *Balsam*). The indoor species grow well and readily from either cuttings or seeds. Some of them also do well when grown as tender annuals in the open ground, although likely to suffer in dry weather and to bleach in bright sun. The remarks under *I. Oliveri*, *I. Sultani*, *I. Holstii*, *I. Hawkeri*, *I. platypetala*, *I. flaccida*, and *I. Hookeriana* indicate the treatment for the greenhouse kinds.

1951. Impatiens pallida.—One of the native jewel-weeds. (×½)

A. *Species of the U. S. and Canada, seldom grown in wild gardens, and frequently found about the borders of damp cult. grounds.*

1. **biflòra**, Walt. (*I. fúlva*, Nutt.). SPOTTED TOUCH-ME-NOT. JEWEL-WEED. Annual, with orange-colored fls. much spotted with reddish brown. spur strongly inflexed, about half as long as posterior sepal: lvs. ovate or oval, petioled and coarsely toothed: usually 2–3 ft. Moist, shady places. July–Oct. Nova Scotia to Alaska, Ore., Mo. and Fla.—Has been offered by dealers in native plants. **I. Nórtonii**, Rydb., of W. Mo. and Kans., differs from *I. biflora* in having larger and relatively longer and narrower saccate sepal which tapers gradually into a shorter spur.

2. **pállida**, Nutt. (*I. aùrea*, S. Wats.). PALE TOUCH-ME-NOT. JEWEL-WEED. Fig. 1951. With *I. biflora* the representatives of the family in the indigenous flora of the U. S. Larger than *I. biflora;* otherwise similar to it, with pale yellow fls. sparingly dotted with brownish red; spur short, notched, and less than one-third the length of the posterior sepal. Moist, shady places. July–Sept. Que. to Ore., Kans. and Ga.—Annual. Perhaps procurable from dealers in native plants.

AA. *Species of familiar flower-gardens: annuals.*

3. **Balsámina**, Linn. GARDEN BALSAM. Figs. 450–453, Vol. I. Annual, erect and branching, pubescent or nearly glabrous: lvs. either narrowly or broadly lanceolate and acuminate, deeply serrate, the petiole glandular: fls. large, rose-colored; standard orbicular and retuse; wings or side petals very broad, with the lateral lobe rounded and the terminal sessile and large; lip small and cone-like; spur variable, incurved: caps. large, tomentose. Trop. and Subtrop. India, Malaya, China.—Very variable in its wide range. Hooker recognizes 6 wild botanical varieties: Var. *vulgàris*, Hook. f. (*Balsámina horténsis*, DC.). Tall: lvs. broadly lanceolate: fls. large, with short spur. Var. *coccínea*, Hook. f. (*Balsámina coccínea*, DC.). Lvs. narrow-lanceolate: fls. of medium size, the spur long and slender. B.M. 1256. Var. *arcuàta*, Hook. f. Diffusely branched: lvs. small and narrow: fls. small, the spur long, slender and arcuate. Var. *macrántha*, Hook. f. Four inches high: lvs. ovate-lanceolate: fls. large, with short spur. Var. *micrántha*, Hook. f. Small, simple: lvs. small, ovate-lanceolate: fls. small, with long and slender spur. Var. *ròsea*, Hook. f. (*I. ròsea*, Lindl.). Tall: lvs. linear-lanceolate: fls. rather small, with lip saccate and spur short and incurved. B.R. 27:27.—*I. Balsamina* now runs into many forms, through long cult. and breeding. See *Balsam.*

AAA. *Species of many countries, mostly of indoor cult., but sometimes grown in the open.*

B. *Lvs. linear: annual.*

4. **oppositifòlia**, Linn. Annual of free-branching habit, very floriferous, erect: lvs. long-narrow-linear, mostly nearly sessile, remotely serrate: fls. about 1 in. diam., rosy red, purplish or pink, on glabrous pedicels; sepals linear, acuminate; wings with broad-obovate terminal lobe and small lateral lobe; lip conical, produced into a short and stout incurved spur. India. G.C. III. 42:102. G.M. 51:321.

BB. *Lvs. ovate to lanceolate: probably all perennial.*

C. *Peduncles axillary, 1-fld. or sometimes 2-fld.*

D. *Spur of fl. much enlarged or swollen at base.*

5. **grandiflòra,** Hemsl. Stout, branching, glabrous: lvs. alternate, stalked, 3–6 in. long, ovate-lanceolate and sinuate-crenate, puckered or blistered above between the nerves, glandular on lower part of blade and on petiole: fls. solitary, to 3 in. across, bright rose-red with crimson stripes on the wing-lobes; sepals 2, green, orbicular-ovate; standard orbicular, erect, short-spurred below the tip; lip 1¾ in. long, swollen, white netted with purple, abruptly narrowed into an incurved spur 1 in. or more long; wings very large, the terminal lobe obovate and the basal orbicular. Madagascar. B.M. 7826. G.C. III. 29:111.

1952. Impatiens Sultani. (×½)

6. **Óliveri,** Wright. Glabrous, reaching 4–8 ft., erect, the sts. pale green: lvs. 4–8 at a node, oblanceolate, acute or acuminate, to 8 in. long, dentate-ciliate: fls. 2¼ in. across, pale lilac or rose-colored, almost white beneath, on 1-fld. peduncles about 2½ in. long; lateral sepals ovate and acuminate, much shorter than the petals; lip ovate, funnel-shaped, with abrupt reflexed mucro; spur 1¾ in. long, curved, slender; standard nearly orbicular, recurved and apiculate at apex; wings deeply 2-lobed, the terminal lobe obovate and the lateral obcordate: fr. oblong. Trop. E. Afr., 6,000–8,000 ft. altitude. B.M. 7960. G.C. III. 40:292. Gn. 66, p. 266. G. 27:288, 405. G.W. 11, p. 1. R.H. 1908:180. A.F. 29:155. Gng. 16:3.—An excellent greenhouse subject and also useful in the open border. It makes a very showy plant when given cool greenhouse treatment, producing a bush 10 ft. through. Prop. readily either by seeds or cuttings, the former being produced freely.

DD. *Spur very slender throughout.*

7. **Sultáni,** Hook. f. Fig. 1952. From 12–24 in. high, with stout st. and branches, rather succulent and green, glabrous: lvs. elliptical or lanceolate and narrowed into a petiole about 1 in. long; lower lvs. alternate, upper ones almost whorled: peduncles axillary; fls. rich scarlet in the original form; petals flat; standard obovate-orbicular and retuse; lip less than half length of petals, suddenly narrowed into a slender upwardly curved long spur. Hybrids and sports have given shades from pink to almost purple, and a white variety also exists. spur is very long and thin. Zanzibar. B.M. 6643. Gn. 23, p. 331. G. 14:283. V. 7:325, 326. S.H. 2:280. I.H. 30:488; 42, p. 140. R.H. 1884:12.—Increased by seeds; also by cuttings, which root readily. A greenhouse plant; it also does well as a house plant, blooming almost continuously. Var. **Epíscopi,** Hort. A perpetual flowering variety with purple-carmine fls. marked brilliant rose.—*I. Sultani* was named by Hooker "in honor of that distinguished potentate, the Sultan of Zanzibar, to whose enlightened and philanthropic rule eastern Africa owes so much." See No. 13.

8. **Hòlstii,** Engler & Warb. Very like *I. Sultani.* Fleshy herb or subshrub, nearly glabrous, 2–3 ft.: the branches striped red: lvs. alternate, long-petioled, oval or ovate to lanceolate, acute, crenate and with a bristle between the teeth: fls. 1 or sometimes 2 on the peduncle, pure scarlet, 1¾ in. across, flat; sepals 3, the lateral small and scale-like; spur slender, 1½ in. long; standard broadly obcordate; lateral petals deeply divided into 2 obovate-spatulate lobes. E. Trop. Afr., 2,500–5,000 ft. B.M. 8029. G.C. III. 38:14. Gn. 72, p. 337; 74, p. 17. G.M. 48:413; 56:46. J.H. III. 51:65. R.H. 1906:136. G.W. 15, p. 356 (as var. *nana amabilis*).—Of better constitution under cult. than *I. Sultani,* having quicker and more vigorous growth, and larger and brighter fls. It is useful either as a pot-plant indoors or for growing in the open; for the latter purpose, seeds may be started early in spring and plants will bloom from early summer till frost. Var. **Liegnítzia,** Grign., is a compact condensed form, with color more clear and brilliant than the type, blooming freely throughout the year; excellent for pot cult. R.H. 1909, p. 279.

9. **Petersiàna,** Rehd. Very like *I. Holstii,* but all the parts red or bronzy rather than green, sts. pubescent, petioles longer: lvs. longer and elliptic rather than oval, peduncles and pedicels longer, fls. carmine-red rather than scarlet and the petals entire, caps. small and purple. W. Trop. Afr. M.D.G. 1905:390 (descr.) R.H. 1910:452.

1953. Impatiens flaccida. (×¼)

10. **Háwkeri,** Bull. A bushy, soft-wooded plant, 2 ft. or less high, with well-branched sts. of a dull red color; lvs. opposite or in whorls of 3, ovate, acuminate, serrate, dark green, pale beneath: peduncles axillary, long and slender; fls. rounded in outline, about 3 in. diam., deep carmine, with a white eye; standard round-obovate, retuse; spur to nearly 3 in. long, slender and slightly curved. South Sea Isls. Intro. about 1886. B.M. 8247. G.C. II. 25:761. I.H. 34:2. Gn.W. 5:213. G.W. 14, p. 126. G.Z. 31, p. 122.—A greenhouse plant, needing an intermediate temperature. Plants from early spring cuttings bloom all summer and into autumn.

11. **platypétala,** Lindl. (*I. pulchérrima,* Dalzell). Sts. strong, succulent, branched and usually reddish purple: lvs. whorled, lanceolate or oval, serrate, hairy beneath: peduncles axillary, shorter than the lvs.; fls. large, rose-colored; spur sickle-shaped, rather thin and petals transversely obcordate. Summer. Java. R.H. 1847:221. B.R. 32:68.—Needs a moderate to warm temperature and may be used as a house-plant or in protected and warm situations outdoors. Prop. by cuttings, and during growth should be treated like gloxinias. Var. Lucie or Lucy belongs here.

12. **fláccida,** Arn. (*I. latifòlia,* Hook., not Linn.). Fig. 1953. Slender but erect, somewhat branched, glabrous, 6–18 in.: lvs. stalked, ovate or lanceolate, crenate, 2–5 in. long, the petiole with or without glands: fls. rose-purple, 1½ in. or less in diam., mostly solitary; sepals ovate; standard broad, 2-lobed, spurred; wings broad, 2-lobed, variable; lip boat-shaped, with a long slender curved spur about 1½ in. long and sometimes parted to the middle: caps. glabrous, ½in. long. India. B.M. 5276, 5625.—Thrives under the treatment given *I. Sultani.* There is a white-fld. form (var. *álba*).

cc. *Peduncles with 3–6 or more fls., often more or less clustered or terminal.*

13. **Hookeriàna,** Arn. (*I. biglandulòsa,* Moon. *I. Sultáni álba,* Hort.). A very succulent much-branched plant, growing to a height of 3 ft.: lvs. long-petioled, ovate-lanceolate, toothed: peduncles axillary in the upper lvs.; fls. large, white, spotted with purple on the large lower petals; spur bent horn-shaped, and longer than the fls. Blooms in fall. Ceylon. B.M. 4704. J.F. 14:391.—It is a perennial, requires a moderate temperature and does not bloom until well developed. Prop. by cuttings. One of the best species in cult.

14. **Róylei,** Walp. (*I. glandulígera,* Royle). Fig. 1954. A rather coarse garden annual, with strong st., succulent and much-branched: lower lvs. opposite; upper lvs. usually in 3's and whorled, all ovate or ovate-lanceolate, naked, 4 in. long, sharply serrate; basal serrations and the petiole glandular: peduncles axillary, with 3 or more fls. and very numerous toward top of plant; fls. large, dark purple; spur very short. Aug., Sept. India, in the Temp. W. Himalaya region, 6,000–8,000 ft. altitude. B.M. 4020. B.R. 26:22. J.F. 4:427.—Grown from seed, needing but little care, and useful in groups. In its native country it grows 4–10 ft. high. Variable. Var. *moschàta,* Hook. (*I. moschàta,* Edgew.), has lvs. alternate and whorled, coarsely serrate and less glandular. Var. *cándida,* Hook. (*I. cándida,* Lindl.), has uppermost lvs. opposite or whorled, and fls. white spotted crimson. J.F. 4:416. Var. *macrochìla,* Hook. (*I. macrochìla,* Lindl.), has upper lvs. alternate; terminal lobes of the wings half-oval (as if one side wanting) and falcate. B.R. 26:8.

15. **Bálfourii,** Hook. f. Glabrous, slenderly branching, 2–3 ft.: lvs. 3–5 in. long, short-stalked, ovate-lanceolate and very long-acuminate, with many minute recurved teeth, glandless: fls. loosely racemose at the top of the st. on very slender pedicels, large, rose and yellow; sepals 2, nearly orbicular, small; standard orbicular, reflexed, white suffused rose; the keel red; wings 1¼ in. long, pale yellow on basal lobe and bright rose on the hatchet-shaped terminal lobe; lip to 1¼ in. long, gradually narrowed into a horn-like somewhat incurved obtuse spur: caps. erect, narrow, to 1½ in. long, red on the angles. W. Himalayas. B.M. 7878.

I. auricoma, Baill. Perennial, 6–24 in.: lvs. alternate, lanceolate, acuminate, crenate and with bristles: fls. golden yellow streaked red within; lateral petals connate; spur short, curved, 2-parted: sts. and midrib reddish. Comoro Isls., Mozambique. B.M. 7381.—*I. chrysántha,* Hook. f. Annual, glabrous: lvs. alternate, lance-ovate, serrate: fls. several on a peduncle, golden-yellow; spur short and incurved. India. B.M. 7786.—*I. comorénsis,* Baker. Lvs. elliptic-lanceolate, acute and crenate: fls. large, bright carmine with 2-parted white spur. Comoro Isls.—*I. comoricoma,* Hort. (I. comorensis × I. auricoma).—*I. cuspidàta,* Wight & Arn. Shrubby, glabrous, farinaceous: lvs. alternate or uppermost opposite, lanceolate or oblong-lanceolate, serrulate: fls. solitary, 1 in. across, very pale red; spur slender. India. Var. *arthrética,* Hook. f., has the lower nodes much thickened. B.M. 7844.—*I. fálcifer,* Hook. f. Annual, more or less decumbent: lvs. alternate, sessile or stalked, ovate to ovate-lanceolate, serrate: fls. solitary and short-pedicelled, ringent, golden yellow spotted blood-red; spur slender, to 1½ in. long. India. B.M. 7923.—*I. Hérzogii,* Schum. Stout branching herb the branches 4-angled: lvs. opposite and whorled, ovate to ovate-lanceolate: fls. solitary or clustered, about 2 in. across, cinnabar; spur to nearly 3 in. long, very slender, incurved. New Guinea. B.M. 8396. R.H. 1913:12.—*I. Hólstani,* Hort. (I. Holstii × I. Sultani).—*I. kewénsis,* Hort. (I. platypetala × I. Herzogii) —*I. Mariánæ,* Reichb. Annual: lvs. cuneate-oblong and acute, serrate with lighter areas between veins: fls. light purple, cymose; standard with a projection below the tip; lip with slender hooked spur. India. G.W. 14, p. 127.—*I. psittacina,* Hook. f. Annual, leafy and much branched: lvs. alternate, ovate, acuminate, serrate: fls. solitary, oddly colored, 2 sepals green, standard pale rose, wings suffused and streaked red, lip white with irregular dash of carmine; spur short and hooked. Burma. B.M. 7809.—*I. Thómsonii,* Hook. f. Annual, erect, 8–12 in.: lvs. alternate, ovate-lanceolate, serrate: fls. several on a peduncle, ¾in. long, pale rose; spur slender, incurved. India. B.M. 7795.

L. H. B.†

1954. Impatiens Roylei. (×⅓)

IMPERÀTA SACCHARIFLÒRA: *Miscanthus.*

IMPERATÒRIA: *Peucedanum.*

INCARVÍLLEA (after Incarville, the French Jesuit missionary to China, correspondent of Jussieu in 1743). *Bignoniàceæ.* Showy herbs, annual, biennial, or perennial, planted in the open.

Closely allied to Amphicome, and the fls. of both have the same general appearance, but in Incarvillea the calyx-lobes are awl-shaped, while in Amphicome the calyx is truncate or shortly dentate; also the seeds of Incarvillea have an entire hyaline wing, while in Amphicome the seeds have a wing that is cut into long thin strips or hairs. The two genera form a small but remarkable group, characterized by their caps. opening by the ventral suture only. Calyx campanulate, 5-lobed; corolla-tube elongated, enlarging; limb somewhat 2-lipped, the lobes 5, spreading and broad; stamens 4, included, didynamous; disk annular or ring-like; ovary 2-loculed: fr. a narrow more or less curved caps. with many seeds: plant erect, branching or simple: lvs. alternate, 2–3-pinnate or simple, with narrow segms.: fls. large, in terminal clusters, red to yellow.—Species about a dozen, Turkestan, Thibet, China. The general experience seems to be that these plants need rather more winter protection than most hardy herbaceous perennials. A light, sandy loam, well enriched and deeply worked, suits them well, and they like a sheltered position in a rather warm, sunny place. Prop. by division or seed.

A. *Lf.-segms. toothed or crenate.*

Delavàyi, Bur. & Franch. Fig. 1955. Lvs. few, radical; lfts. 4–5 in. long, not quite opposite: stamens included. B.M. 7462. Gn. 54:430; 60, p. 229; 72, p. 421. G. 23:157. Gn.W. 15:713. G.W. 15, p. 409. R.H. 1893:544. J.H. III. 30:449. Gt. 43:1398. Mn. 3, p. 26. G.C. III. 26:123. G.M. 38:306.—*I. Delavayi* is a hardy plant with handsome pinnate foliage, each lf. being 1 ft. long, with as many as 15–20 dentate segms.: scape 1–2 ft. high, bearing 2–12 large trumpet-shaped rosy purple fls., each 2–3 in. long and as much wide. These fls. are probably equal in decorative value to many of the bignonias cherished in greenhouses. In size and beauty they rank with those of catalpa, bignonia and tecoma, of the same family. The tube is yellow inside and out, and the 2 upper lobes are smaller than the 3 lower ones.

lùtea, Bur. & Franch. Two to 4 ft.: lvs. mostly radical, 8–15 in. long, pinnate, long-petioled; lfts. broad-lanceolate, crenate: scapes stout and stiff, bearing a few bracts and 6–20 yellow, somewhat pendulous fls., with limb 2 in. across and paler yellow than the tube. S. W. China, 10,000–12,000 ft. altitude. G.C. III. 50, suppl. Aug. 19 (1911).

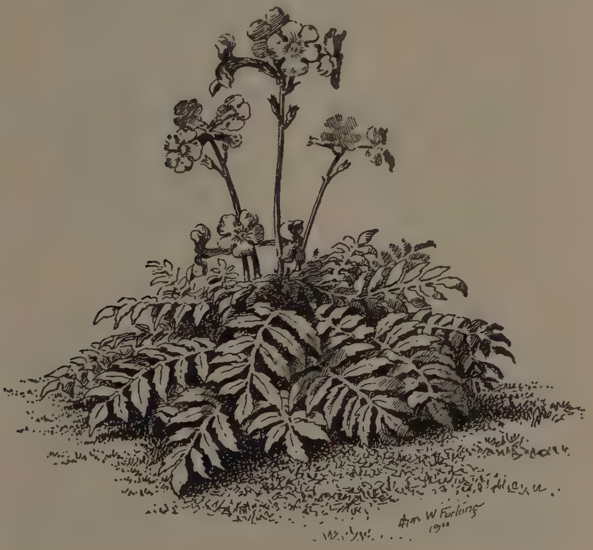
AA. *Lf.-segms. parted or dissected.*

variábilis, Batalin. Subshrub: lvs. 2- or 3-pinnate; segms. parted or dissected, their lobes entire or slightly lobed: fls. as many as 10, pale rose. Gt. 47, p. 222.—A strong-growing, bushy plant covered with fls. each 1 in. or more across, from May to Oct.: seedlings bloom the first year.

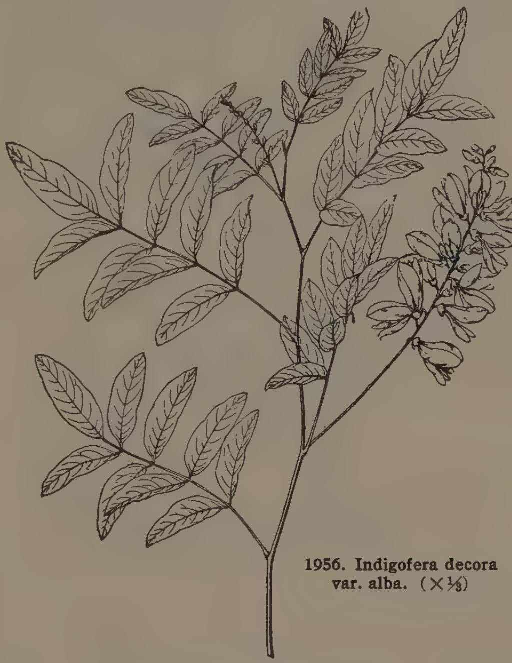
AAA. *Lf.-segms. often entire or nearly so.*

Ólgæ, Regel (*I. Koòpmannii,* W. Lauche). Subshrub, 2–3 ft. high: lvs. 2–4 in. long; segms. linear-oblong or lanceolate, narrower than in *I. Delavayi,* especially at the base, entire or with a few distant teeth toward the tip: fls. pale pink, veiny; tube 1½ in. long; limb about 1 in. across, the 5 lobes nearly equal. B.M. 6593 (throat not yellow). G.C. II. 19:89. Gn. 28, p. 653.—The hardiest species.

grandiflòra, Bur. & Franch. Differs from *I. Delavayi* in its shorter lvs., more rounded lfts., segms. ovate or broader, short scapes bearing only 1 or 2 fls. as large as those of *I. Delavayi,* but with narrower calyx-lobes and longer corolla-lobes, the color deep rose-red. Dried specimens show about a dozen scapes on a plant. China. Gn. 56:22. J.H. III. 46:357. G. 27:349; 35:145. G.M. 46:219. Var. **brévipes,** Sprague (*I. Bonvalòtii,* Hort., not Bur. & Franch.), is offered abroad: "large brilliant crimson fls., habit of *I. Delavayi:*" pedicels much shorter than the peduncle. Yunnan, China.



1955. Incarvillea Delavayi.



1956. Indigofera decora var. alba. (×⅓)

compácta, Maxim. Handsome hardy perennial, glabrous or somewhat pubescent: st. short, becoming 1 ft. or more high: lvs. fleshy or thick, mostly radical, pinnatisect; segms. subcordate-ovate, all more or less decurrent, entire or nearly so: fls. at first congested near the crown, but becoming elevated, purple, the corolla 2–2½ in. long and the limb 1½ in. across; corolla-tube dilated, the limb broad and with roundish lobes; calyx-teeth deltoid, acuminate. N. W. China. Gt. 49:1479.

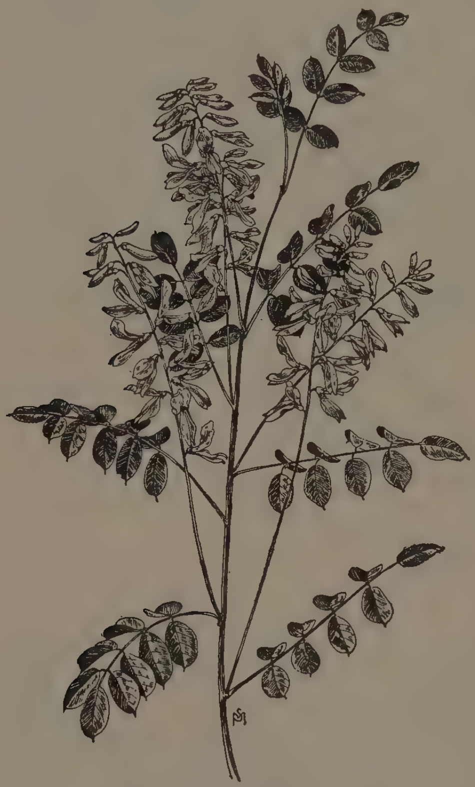
INDIGO: *Indigofera.* **False Indigo:** *Baptisia* and *Amorpha.*

INDIGÓFERA (*indigo-bearing*). *Leguminòsæ.* INDIGO. Shrubs and perennial herbs sometimes grown for ornament, and some species cultivated in various parts of the world for indigo.

Plants of differing habit, more or less silky-hairy: lvs. odd-pinnate (rarely digitate), or sometimes simple (1-foliolate): fls. usually small, in axillary racemes or spikes, in color ranging from purple to rose and white, papilionaceous; standard mostly roundish, often persisting for some time; keel with a spur or swelling on either side; stamens 10, monadelphous, or 9 and 1: pod various, usually with thin partitions between the seeds.—The species are probably 300, in tropical regions of the world, and extending to the Cape region of S. Afr. Several species are native to the U. S.

Indigo is mostly the product of *I. tinctoria,* of Asia, but it is also made from the West Indian species, *I. Anil*. These species were early introduced into the southern states for indigo-making, and the product was once manufactured to a considerable extent. The plant was introduced into South Carolina in 1742 from the West Indies. When it was found that commercial indigo could be produced, the British Government offered a bounty. In 1775, the production was more than one million pounds of indigo. The war for independence checked the industry, and thereafter the rising importance of the cotton crop, amongst other things, drove it to the wall. But as late as the middle of the last century, indigo continued to be made in remote places. Plants still persist in some places as escapes from cultivation. *I. tinctoria* is perennial, but is grown from seeds, which give from two to four cuttings of herbage the first year. The indigo is not contained in the plant, but the dye is a product of manufacture from a glucoside indican which is contained in the herbage, and which is obtained as an extract. Indigo seed is offered by seedsmen. Other species, even of other genera, also yield indigo. Very much of the indigo of commerce is now manufactured synthetically from coal-tar.



1957. Indigofera Kirilowii. (×⅜)

In North America, several species of Indigofera are occasionally grown as ornamental subjects. In the North, they are mostly greenhouse subjects. Propagated by seeds or cuttings, chiefly the latter. Recent introductions are *I. amblyantha* and *I. Kirilowii*, excellent species and hardy at the Arnold Arboretum.

A. *Raceme longer than the lf.*

decòra, Lindl. Weak-growing or even half-climbing shrub, the branches slender and red-tinged: lfts. in 6–8 pairs, broad-lanceolate, usually drooping, sharp-pointed: racemes long, with showy rose-pink fls. about 1 in. long; standard oblong, nearly or quite obtuse, with a heart-like mark near the base; wings linear-lanceolate or spatulate, ciliate. China. B.R. 32:22. B.M. 5063. G.M. 31:591. P.M. 16:290.—Regarded as a greenhouse plant and cult. in the open far S. Var. **álba** (Fig. 1956), with white fls., is a hardy herbaceous or half-shrubby plant at the Arnold Arboretum, Boston. G.F. 7, pp. 266, 376; fig. 61, p. 375 (adapted in Fig. 1956).

macróstachys, Vent. Shrubby, the sts. terete and appressed-pubescent: lfts. 8–10 pairs, oval-oblong, obtuse but mucronate, pubescent: racemes longer than the lvs., many-fld.; fls. rose. China. V.F. 53.

caroliniàna, Walt. Tall and branching, 6–7 ft.: lfts. 4–8 pairs, oblong, oval or oblanceolate, mucronate, with slender petiolules: fls. small, many, yellowish brown and with short-acute calyx-teeth: legume oblong, 2-seeded, less than ½in. long.—Perennial, in the pine-barrens from N. C. south.

Kirilòwii, Maxim. Fig. 1957. A beautiful species of recent intro., with fls. as large as those of *Robinia Pseudacacia*, bright rose-color: lvs. petioled: subshrub, 3–4 ft., soon glabrous, the branches slightly angular and bark soon striate: lf.-blade to 5 in. long, the stalk to 1⅛ in.; lfts. about 7–9, usually opposite, elliptic or rounded-elliptic, obtuse and mucronate, to 1¼ in. long and 1 in. wide, both surfaces bearing white hairs attached by their centers: racemes axillary, longer than the lvs., the peduncle about twice as long as the petiole; corolla glabrous nearly throughout when in bud; standard oblong-elliptic, ⅔in. long and half as wide, ciliate; keel acuminate, ciliate, as long as standard; anthers prominently apiculate. N. China, Korea. B.M. 8580. M.D.G. 1912:271.—Prop. by division, suckers and cuttings; appears not to seed in cult.

AA. *Raceme mostly shorter than, or not exceeding, the lf.*

amblyántha, Craib. Upright shrub, 3–6 ft.: young branchlets angled, whitish from appressed hairs: lvs. petioled, 4–6 in. long; lfts. usually opposite, oval to elliptic-oblong, broadly cuneate at the base, rounded and mucronate at the apex, bright green above, glaucescent beneath, appressed-pubescent on both sides, ½–1½ in. long: fls. in axillary slender racemes with the peduncle 2½–4 in. long, very numerous, pink, small, ¼in. long; petals narrow, of nearly equal length; standard spatulate-obovate, upright, incurved at the apex; calyx appressed-pubescent; ovary densely whitish pubescent: pod linear, with both sutures thickened, pubescent, 1½–2 in. long. July–Oct. Cent. China.—A handsome shrub with its numerous dense racemes of small pink flowers blooming all summer and autumn. Hardy at Arnold Arboretum. Prop. by cuttings, and by seeds which are freely produced.

austràlis, Willd. (*I. angulàta*, Lindl. *I. sylvática*, Sieb.). A very variable species, known by its glabrous aspect, short or nearly obsolete teeth of the calyx and the pod glabrous when young. Erect shrub: lfts. 9–17, varying from oblong to almost orbicular, ¾in. or less long, obtuse or retuse: fls. red and mostly showy, the racemes sometimes fully as long as the lvs.; standard truncate at the base with a very short claw: pod nearly or quite straight, terete. Austral. B.M. 3000. B.R. 386; 991. L.B.C. 2:149.

tinctòria, Linn. INDIGO. Fig. 1958. Shrub, 4–6 ft., with silvery branches: lfts. 7–15, thin, rather large, obovate-oblong, pubescent beneath: fls. small, reddish yellow, in short racemes, the pedicels finally recurved; calyx pubescent, the lobes subulate: pod nearly straight, somewhat knotty, 8–12-seeded, about ¾ or 1 in. long. S. Asia.—Long cult. and widely distributed. Runs wild S. Indigo was known to the Egyptians.

Ánil, Linn. WEST INDIAN INDIGO. Fig. 1958. Much like the last, but fls. smaller, and pods curved and not knotty, and about ½in. long. W. Indies, but now runs wild in the southern states. B.M. 6506.

Gerardiàna, Wall. (*I. Dosùa,* Hort., not Hamilt.). Low much-branched shrub with silvery canescent branchlets: lvs. 1–2 in. long, with thickish opposite pale white bristly lfts. to ½ in. long and oblanceolate-oblong and 9–17 in number: fls. pale red, canescent outside, the peduncled racemes 12–20-fld.: pod to 2 in. long, nearly cylindrical. India. B.R. 28:57.

I. caudàta, Dunn. Shrubby, 3–8 ft., with a coppery pubescence on young growths: fls. white, about ⅓in. long, in very long tail-like racemes that droop at the end. China.—*I. hebepétala,* Benth. Branching shrub, lightly pubescent when young: lvs. 4–7 in. long; lfts. 4–8 pairs, oblong, about 2 in. long: fls. small, reddish, in short axillary racemes. Himalayas. B.M. 8208.—*I. reticulàta,* Franch. Similar to I. Kirilowii, but dwarfer: lvs. dark shining green: fls. clear white. China, Korea. The plant in cult. may be I. reticulata, Koehne.

L. H. B.

ÍNGA (a West Indian name). *Leguminòsæ.* Tropical trees and shrubs, with acacia-like foliage and clusters of showy red stamens.

Spineless: lvs. abruptly pinnate, usually with glands between the large lfts.: fls. not papilionaceous, in heads, spikes, racemes or umbels, mostly 5-merous; stamens ∞, monadelphous, exserted beyond the small tubular or campanulate corolla: pod narrow, often thickened at the sutures, completely or partially indehiscent.—Species upward of 150, in W. Indies and S. Amer.

A. *Lfts. hairy beneath.*

affinis, DC. Lvs. simply pinnate; lfts. in 4 pairs, ovate, acuminate, pubescent above, somewhat shining and villous below, one side smaller than the other, 3 in. long, 1½ in. wide; petioles, branches, peduncles and fls. velvety tomentose, a gland between each pair of lvs.: spikes solitary or in pairs; corollas villous. Trop Amer.

1958. Indigofera Anil. (Nearly natural size.) The single pod is I. tinctora. (×½)

AA. *Lfts. not hairy.*

Feuillei, DC. Foliage handsome; lvs. simply pinnate; lfts. in 3–4 pairs, oval-oblong, acute at both ends, glabrous: pods 1–2 ft. long, linear, flat, glabrous, white inside. Peru.—The sweet, edible pulp of the pods is much prized by the Peruvians, who call it pacay. It has ripened its pods in Calif.

I. anómala, Hort.=Dichrostachys nutans.—*I. dúlcis,* Willd.=Pithecolobium.—*I. guadalupénsis,* Desv.=Pithecolobium.

Wilhelm Miller.
L. H. B.†

INGENHOÙZIA (Dr. John Ingenhousz, 1730–1799, famous vegetable physiologist). *Malvàceæ.* A sub-shrubby plant of S. Ariz. and Mex., intro. recently in S. Calif. for ornament. Allied to Gossypium: involucel of 3 triangular-lanceolate entire bracts; calyx saucer-shaped; stigma obscurely 3-lobed: fr. a globular leathery 3-celled and 3-valved caps.; seeds 5–8 in each cell or locule, puberulent. **I. tríloba,** DC. Perennial, 4–10 ft., glabrous: lvs. 3-parted or 5-parted, or the uppermost entire and lanceolate, the lvs. and branches black-dotted: fls. on axillary peduncles, or somewhat corymbose above; petals 1 in. long, pure white turning to rose, dark-dotted. Generic name variously spelled.

INOBÚLBON (in reference to fibrillose bulbs). *Orchidàceæ.* Pseudobulbs short, few-jointed, annulate, fibrillose, few-lvd.: fls. in racemes or panicles; sepals and petals equal, the lateral sepals not forming a mentum; lip 3-lobed, the lateral lobes small, the middle lobe large, with a thick fleshy callus 3-parted disk; column short, footless.—Species 2, New Caledonia.

muníficum, Kränzl. (*Dendròbium muricàtum* var. *muníficum,* Finet). Pseudobulbs about 3 in. long, 1½ in. thick, 2-lvd.: lvs. up to 8 in. long: panicle of few branches, somewhat nodding; sepals and petals greenish, brown-spotted; lip marked with reddish purple and yellow. B.M. 8371.

INSPECTION OF HORTICULTURAL MERCHANDISE.—To guard against the introduction of insect pests and plant diseases, governments have instituted inspection service at ports of entry and for interstate commerce. The regulations may be federal, or state or provincial.

The plant-quarantine act.

A federal plant-quarantine act was enacted by Congress August 20, 1912. This act authorizes the Secretary of Agriculture to regulate the importation of nursery stock and other plants and plant-products, and to establish and maintain quarantine districts for plant-diseases and insect pests within the United States, and also to exclude by quarantine diseased plants or plant-products from foreign countries or to provide such regulations governing the entry of such materials as will insure safety.

The first general attempt to secure national legislation of this nature resulted from the introduction of the San José scale into the eastern United States and its threatened general distribution on nursery stock. To meet this emergency, a convention was called in Washington in 1897, composed of the delegates from horticultural societies, nurserymen's associations, state agricultural boards, agricultural colleges and experiment stations—a large and representative body of men. After full discussion a bill was drafted, the primary object of which was the control of domestic nursery stock, but which provided also for the inspection of foreign nursery stock. While this measure received the endorsement of the convention, and was submitted to Congress, the different interests were not fully agreed as to the desirability of all its features, and it was not heartily pushed and was ultimately dropped with the idea of replacing it by a more suitable bill.

During succeeding years, a number of bills covering the same general subject were introduced at the different sessions of Congress, and some of these were reported favorably from the Committee on Agriculture, but the opposition of importing nurserymen prevented any of these measures ever reaching a very advanced stage. In the meantime, various conferences were held between the entomologists of the different states and horticultural inspectors and the principal nurserymen's associations, without, however, coming to any agreement as to suitable legislation. Finally, in 1908, the promoters of this legislation having become thoroughly discouraged, the project was definitely abandoned,—the San José scale in the meantime having been carried on nursery stock into practically every state in the Union.

The effort which eventually resulted in the enactment of the present law was due to the discovery, in 1909, of the introduction of enormous quantities of brown-tail moth nests full of hibernating larvæ on seedling fruit stock, chiefly from northern France and Belgium. With these were occasional egg-masses of the gipsy-moth. During the years 1909 and 1910, stock infested with thousands of larval nests was sent to no less than twenty-two different states, covering the country from the Atlantic seaboard to the Rocky Mountains. So far as possible, this stock was followed up by state and federal inspectors and the infesting insects destroyed.

This new danger led the writer in 1909 to draft a national quarantine and inspection bill relating particularly to imported nursery stock, and other plants and plant-products offered for entry from foreign countries, but providing also means for quarantining new pests locally established within the United States. This bill promptly passed the House, but was objected to by nurserymen, and was withdrawn with the idea of revising it so as to meet in a satisfactory way these objections. There followed many attempts to draft a measure which would give reasonable protection and be at the same time satisfactory to the nursery interests, and many different bills were introduced in Congress from time to time, all based on the original bill just referred to. Securing desirable legislation of this kind—against a small but organized opposition—is a slow process, and the effort instituted in January, 1909, did not reach fruition until August, 1912. The passage of the act was finally much aided by the hearty coöperation of Californian interests, due to the discovery that the Mediterranean fruit-fly had become thoroughly established in Hawaii and was likely at any time to be carried by Hawaiian fruits to California, and thus jeopardize the vast fruit development of that state.

The bill as passed is a compromise measure, and divides responsibility between the federal government and the state authorities. It, furthermore, gives no control over the interstate movement of domestic nursery stock, except as to areas and plants specifically quarantined.

The scope of this act has been given in an opening paragraph. The system of control of imported nursery stock and a description of the several foreign and domestic plant quarantines and restrictive orders follow.

Control of nursery stock importations.

For the purposes of this act, nursery stock offered for entry into the United States falls into two classes, namely:

1. That coming from countries having an official inspection and certification system, and
2. From countries which have no system of inspection or certification.

Nursery stock from the first class of countries, arrives with some assurance of freedom, or at least the responsibility for its condition fixed on some known foreign official.

Nursery stock from the second class of countries arrives with no information as to its probable freedom from infestation by insects or diseases.

Commercial importations are permitted only from the countries belonging to the first category, and from countries belonging to the second category importations are limited by regulation and permitted only for experimental or scientific purposes. Mail importations are not permitted except of field, vegetable, and flower seeds.

The following countries have provided for inspection and certification of export plants and plant-products in conformity with the regulations under the plant-quarantine act: Australia, Barbados, Belgium, Bermuda, British Guiana, Canada, Cuba, Denmark, England, France, Germany, Guatemala, Holland, Ireland, Japan, Leeward Islands, Antigua, St. Christopher-Nevis, Dominica, Montserrat, Virgin Islands, Grand Duchy of Luxemburg, New Zealand, Scotland, Union of South Africa, Straits Settlements, Switzerland, Trinidad, Wales, Windward Islands, Granada, St. Lucia, and St. Vincent; and these include most of the countries which have hitherto maintained any considerable commerical trade in nursery stock with the United States. Any other country may obtain the benefits of commercial exportation by providing for the proper inspection and certification of exported stock. The Italian government has indicated that the Province of Padua will certify export nursery stock, and a national law has been passed with the object of ultimately meeting for the country as a whole the requirements of the plant-quarantine act.

The federal act has very greatly stimulated those foreign countries which have considerable commercial trade in plants with the United States to do better work of inspection and to provide suitable legislation and officers to meet the requirements of the act.

The United States is no longer a dumping-ground for any sort of infested and diseased stock. Brown-tail moth and gipsy-moth infestation has practically ceased, insect infestation by any important pest is rare, and the general condition of the stock has been very much improved.

In general explanation of the federal powers in relation to the importation of nursery stock, it may be said that these powers relate (1) to the issuance of permits for the importation of nursery stock, (2) the provision for foreign inspection and certification as a condition of entry, and (3) the distribution to the several state inspectors of exact information in regard to the origin, arrival, and destination of the imported stock.

To the several states is left the entire responsibility for the inspection at destination of commercial importations of nursery stock, and, if this inspection is not done by state inspectors, there is nothing in the federal law to make good this neglect. Most of the states have made fairly adequate provision for such inspection, and this inspection, as shown by the pests intercepted and destroyed, has been of tremendous value.

Foreign plant quarantines.

Under the provisions of Section 7 of the plant-quarantine act, the following foreign plant-quarantines have been established:

White pine blister-rust.—This is Quarantine No. 1, promulgated September 16, 1912, and amended and superseded by Quarantine No. 7, promulgated May 21, 1913. This quarantine was drawn to prevent the introduction into the United States of the white pine blister-rust, and forbids the importation into the United States from each and every country of Europe and Asia of all five-leafed pines.

Potato wart.—This is Quarantine No. 3, promulgated September 20, 1912, to prevent the introduction into the United States of the disease known as "potato wart," "potato canker," "black scab," and the like, and forbids the importation into the United States from the countries of Newfoundland, the islands of St. Pierre and Miquelon, Great Britain and Ireland, Germany, and Austria-Hungary, of the common or Irish potato (*Solanum tuberosum*).

Mexican fruit-fly.—This is Quarantine No. 5, and was promulgated January 15, 1913, to prevent the introduction into the United States from Mexico of the insect known as the Mexican fruit-fly (*Trypeta ludens*), and forbids the importation into the United States from the Republic of Mexico of the following fruits: oranges, sweet limes, mangoes, *Achras Sapota*, peaches, guavas, and plums. It was amended February 8, 1913, to include, in addition to the above fruits, the grapefruit and its horticultural varieties.

Pink boll-worm of cotton.—This is Quarantine No. 8, promulgated May 28, 1913, to prevent the introduction into the United Sates of the pink boll-worm of cotton, and forbids the importation into the United States of cotton-seed of all species and varieties and cotton-seed hulls from any foreign locality and country, excepting only the locality of the Imperial Valley in the state of Lower California in Mexico. The importation from the region specified in Mexico is governed by regulations. By later amendments this quarantine was lifted and cotton-seed and seed-cotton were permitted to be entered, under regulations, from the Mexican states of Neuvo Leon, Tamaulipas, Coahuila, Durango, and Chihuahua.

Potato quarantine.—This is Quarantine No. 11, promulgated December 22, 1913, to prevent the introduction into the United States of the disease known as powdery scab (*Spongospora subterranea*), and forbids the importation into the United States from the Dominion of Canada, Newfoundland, the islands of St. Pierre and Miquelon, Great Britain, Ireland and Continental Europe, of the common or Irish potato (*Solanum tuberosum*), until such time as it shall have been ascertained to the satisfaction of the Secretary of Agriculture that the country or locality from which potatoes are offered for import is free from powdery scab and other injurious potato diseases. Amendments 1 and 2, February 20; 3, March 12; and 5, November 30, 1914, eliminate Belgium, Denmark, and the Netherlands, and the Dominion of Canada, from the provisions of this quarantine and make it possible to import potatoes under regulation from these countries. The importation under regulation is also now permitted from Bermuda, Santo Domingo, and the states of Chihuahua and Sonora, Mexico. Amendment 4 to this quarantine, promulgated June 25, 1914, eliminates the territory of Porto Rico from its provisions.

Avocado seed quarantine.—This is Quarantine No. 12, promulgated February 27, 1914, to prevent the introduction into the United States of the avocado weevil (*Heilipus lauri*), and forbids the importation into the United States of the seeds of the avocado or alligator pear from Mexico and the countries of Central America.

Sugar-cane quarantine.—This is Quarantine No. 15, promulgated June 6, 1914, to prevent the introduction into the United States of injurious insects and fungous diseases of the sugar-cane, and forbids the importation into the United States, from all foreign countries of living canes of sugar-cane, or cuttings or parts thereof. This quarantine does not apply to Hawaii and Porto Rico.

These foreign quarantine orders are absolute prohibitions of the entry of the goods covered, and are enforced through the active coöperation of the customs service of the Treasury Department.

Domestic plant quarantines.

Under the provisions of section 8 of the plant-quarantine act the following domestic plant-quarantines have been established:

Mediterranean fruit-fly.—This is Quarantine No. 2, promulgated September 18, 1912, to protect the United States from the entry of the Mediterranean fruit-fly, now thoroughly established in the Hawaiian Islands. This quarantine prohibits the shipment of any of the fruits and vegetables specified in the notice of quarantine into or through any other state, territory, or district of the United States.

Gipsy-moth and brown-tail moth.—This is Quarantine No. 4, promulgated November 5, 1912, and revised and amended as Quarantine No. 10, June 24, 1913, and as Quarantine No. 17, July 3, 1914. This quarantine describes and quarantines the districts in New England infested by the two moths named, and makes regulations governing the movement in interstate commerce of plants and plant-products which may be infested from the areas quarantined.

Date-palm scale insects.—This is Quarantine No. 6, promulgated March 1, 1913, to prevent the further distribution in the United States of two important date-palm scale insects. It quarantines certain counties in California, Arizona and Texas, and makes regulations governing the interstate movement of date palms originating within the areas quarantined.

Pink boll-worm of cotton.—This is Quarantine No. 9, promulgated June 24, 1913, and applies to the territory of Hawaii. It has the same object as the foreign quarantine on the same subject, described above. It prevents the movement from the territory of Hawaii into or through any other state, territory or district of the United States of all cotton-seed and cotton-seed hulls.

Mediterranean fruit-fly and melon-fly.—This is Quarantine No. 2, promulgated September 18, 1913, and revised and amended as Quarantine No. 13, promulgated March 23, 1914, to protect the United States from the entry of the Mediterranean fruit-fly (*Ceratitis capitata*) and the melon-fly (*Dacus cucurbitæ*), now thoroughly established in the Hawaiian Islands. This quarantine prohibits the shipment of any of the fruits, nuts and vegetables specified in the notice of quarantine into or through any other state, territory or district of the United States, in accordance with the regulations prescribed under this quarantine. This quarantine became effective May 1, 1914.

Powdery scab of potatoes.—This is Quarantine No. 14, promulgated April 25, 1914, to prevent the further distribution in the United States of the dangerous potato disease known as powdery scab (*Spongospora subterranea*), which exists in certain parts of the state of Maine. This quarantine became effective August 1, 1914.

Sugar-cane quarantine.—This is Quarantine No. 16, promulgated June 6, 1914, to prevent the further distribution in the United States of certain injurious insects and fungous diseases of the sugar-cane existing in the territories of Hawaii and Porto Rico, and forbids the movement from the territories named into or through any other state, territory or district of the United States of living canes of sugar-cane, or cuttings or parts thereof.

Most of the domestic quarantines provide for the movement of the quarantined articles under a system of inspection and certification. The very considerable work of inspection and certification necessitated, particularly in the case of the moth quarantine in New England and the Mediterranean fruit-fly quarantine in Hawaii, is done under federal authority, in coöperation with state and insular officers, who are made for that purpose collaborators of the Department of Agriculture.

Regulatory orders.

Under the authority given by section 5 of the plant-quarantine act, orders placing restrictions on the importation of potatoes and avocados have been promulgated.

The order restricting the admission of all foreign potatoes not under quarantine was issued December 22, 1913, and regulations governing the entry of potatoes under this order into the United States were issued December 30, 1913. This order specifies that potatoes may be imported only from countries which are free from injurious potato diseases and insect pests and under permit and prior foreign inspection and certification. All such imported potatoes are subject to a second inspection by a federal inspector on their arrival in this country.

The order governing the admission of the avocado or alligator pear under restriction was issued February 27, 1914. These two orders are supplemental to the quarantine orders described above in relation to the potato and to avocada seed.

The federal horticultural board.

The act provides (section 12) that for the purpose of carrying out its provisions there shall be appointed by the Secretary of Agriculture from existing bureaus and offices in the Department of Agriculture, including the Bureau of Entomology, the Bureau of Plant Industry, and the Forest Service, a Federal Horticultural Board consisting of five members, of whom not more than two shall be appointed from any one bureau or office, and who shall serve without additional compensation.

State legislation.

The state of California for the last twenty years has enforced a quarantine at the port of San Francisco, and has had quarantine and other control legislation which has furnished protection to the state of untold value, and to a less degree to the remainder of the United States. A few other states have had minor plant-legislation, but the San José scale outbreak in the East in the early nineties, already referred to, was the inciting cause of plant-legislation in nearly every state of the Union. This legislation, chiefly in relation to domestic nursery stock, lacks uniformity, and thus entails unnecessary difficulty to dealers in nursery and other plant stock. An effort has been under way for several years to devise, for general adoption, a uniform nursery and plant act, and it seems now possible that uniform legislation may eventually be secured. A bill has been drafted by J. G. Sanders, State Entomologist of Wisconsin, as Chairman of a Committee on Uniform State Legislation of the American Association of Horticultural Inspectors, and this bill has been approved by this association, representing the different states and by the National Nurserymen's Association. It will probably be many years, however, before it is generally substituted for present state legislation on this subject.

Space at disposal does not permit of a full analysis of the plant legislation of the different states. This legislation has been well summarized in Circular No. 103 of the Department of Agriculture of the state of New York. Shippers of nursery stock should first inquire as to legislation, which may vary from year to year, of any state to which goods are to be sent. Many of the states also require the taking out of licenses, and in some states imported nursery stock must be reëxamined by local state inspectors before it can be liberated.

Plant legislation in Canada.

The Canadian legislation to control the entry of injurious insect pests and plant-diseases has much the same history as the similar legislation in the United States and the same inciting causes. The San José scale excitement in the United States led in 1898 to the passage by Canada of the San José Scale Act which prohibited the importation of nursery stock from all countries in which this scale insect occurred. Later (1901) this prohibition was removed and nursery stock from countries in which the scale occurred was allowed to enter, subject to fumigation with hydrocyanic-acid gas,—the ports of entry and the time of the year when such entry could be made being limited. In 1909 brown-tail moth nests were found on shipments of nursery stock to Canada and this led to the enactment of the "Destructive Insect and Pest Act" of May, 1910. This act provides either for the prohibition of entry, fumigation on entry, or inspection subsequent to entry, of nursery stock, and gives other conditions governing the introduction of living plants. The act has been amended by additional regulations from time to time, particularly in relation to the chestnut-bark disease, the Mediterranean fruit-fly, potato diseases, and forest products from New England.

Canadian provincial legislation.

In addition to the legislation of the Dominion of Canada against insect pests and plant-diseases, several of the provincial governments have enacted similar laws. With the exception, however, of the provinces of British Columbia and Nova Scotia, the provincial governments restrict their attention to the control of pests within their territories. The provinces of British Columbia and Nova Scotia, however, inspect and fumigate, if necessary, nursery stock and fruit imported into these provinces. Nova Scotia fumigates and inspects stock coming from other parts of Canada only. As in the case of the United States, there is coöperation between the inspection service of the Dominion and provincial governments. The full text of the Canadian Dominion and provincial laws in relation to this subject may be obtained from the Dominion Department of Agriculture, Ottawa.

C. L. MARLATT.

Quarantine laws.

State quarantine laws are now in a transition stage. For two or three years there has been active propaganda for uniform state legislation looking to the control of destructive insects and plant diseases. The statutory requirements in the different states are so unlike as to cause much annoyance, and state departments of agriculture or other bodies issue circulars explaining these different requirements for the guidance of nurserymen and others. The bill drafted by the Sanders Committee, already mentioned, has been practically completed, and now awaits enactment. At the request of the Federal Horticultural Board, the Solicitor of the United States Department of Agriculture has drawn a bill for enactment by the different states, to constitute a general plant act rather than a nursery-stock act. Several states are now proposing to enact this draft.

Even in view of the tentative character of much of the legislation, it seems to be well to reprint here a few of the standard or most important statutes. The Canadian law is the simplest and most direct. It embodies in a few words the power to control the entry of plants from foreign countries and also to control the plants within the Dominion. Under the federal and state constitutions in the United States, such a brief and simple law seems to be impossible. There are here printed, the Canadian law; the United States law; and the laws of New York and California.

The ideal law is probably one that confers broad powers, and then leaves the details to regulation so that necessary minor changes may be made as circumstances arise. There must naturally be considerable discretion conferred on competent officers or authorities in dealing with such subjects as quarantine of insects and plant diseases.

Under the federal quarantine act of the United States, some twenty quarantines have now been laid and several of these have required rather elaborate regulations, and modifying orders and amendments have been issued; these matters cannot, of course, be entered here.

Some of the leading sections in the Sanders' bill, now proposed for legislation in the different states, are reprinted on pages 1653 and 1654. This bill is likely to become of much importance in inspection legislation.

The Destructive Insect and Pest Act of Canada (May 4, 1910).

1. This Act may be cited as *The Destructive Insect and Pest Act.*

2. In this Act, unless the context otherwise requires, 'the Minister' means 'the Minister of Agriculture.'

3. The Governor in Council may make such regulations as are deemed expedient to prevent the introduction or admission into Canada, or the spreading therein, of any insect, pest or disease destructive to vegetation.

4. Such regulations may provide,—

(*a*) for the prohibition generally, or from any particular country or place, of the introduction or admission into Canada of any vegetable or other matter likely to introduce any such insect, pest or disease;

(*b*) the terms or conditions upon, and the places at which any such vegetable or other matter may be introduced or admitted into Canada;

(*c*) for the treatment and manner of treatment to be given to any vegetation, vegetable matter or premises in order to prevent the spreading of any such insect, pest or disease, and may prescribe whether such treatment shall be given by the owner or by a person appointed for such purpose;

(*d*) for the destruction of any crop, tree, bush or other vegetation or vegetable matter or containers thereof infested or suspected to be infested with any such insect, pest or disease;

(*e*) for the granting of compensation for any such crop, tree, bush or other vegetation or containers thereof so destroyed, such compensation not to exceed two-thirds of the value of the matter destroyed and to be granted only by the Governor in Council upon the recommendation of the Minister;

(*f*) for the prohibition of the sale of any vegetable matter infected with any such insect, pest or disease;

(*g*) that the occupier of the premises on which is discovered any such insect, pest or disease shall forthwith notify the Minister and shall also send specimens of such insect, pest or disease;

(*h*) for the confiscation of any vegetable matter and the container thereof, if any, in respect of which a breach of this Act, or any regulation made thereunder, is committed, and generally for any other purpose which may be deemed expedient for carrying out this Act, whether such other regulations are of the kind enumerated in this section or not.

5. The Minister may appoint inspectors and other officers for carrying out this Act and the regulations made thereunder.

(2) Such appointments, if not confirmed by the Governor in Council within thirty days of the date thereof, shall lapse and cease to be valid.

6. Any inspector or other officer so appointed may enter any place or premises in which he has reason to believe there exists any such insect, pest or disease, and may take specimens thereof and also of any vegetable matter infested or suspected of being infested therewith.

7. The Minister, upon the report of any inspector setting forth a reasonable belief of the existence of any such insect, pest or disease in any area defined in such report, may prohibit the removal from such area or the movement therein of any vegetation, vegetable or other matter which, in his opinion, is likely to result in the spread of such insect, pest or disease.

8. Every person who contravenes any provision of this Act, or any regulation made thereunder, shall be liable, upon summary conviction, to a fine not exceeding one hundred dollars, or to imprisonment for a term not exceeding six months, or to both fine and imprisonment. Any vegetable or other matter imported or brought into Canada contrary to this Act, or to any regulation made thereunder, shall be forfeited to the Crown.

9. Every order in council and regulation made under this Act shall be published in "The Canada Gazette," and shall be laid, by the Minister, before Parliament within fifteen days after the commencement of the then next session.

The United States Plant Quarantine.

AN ACT To regulate the importation of nursery stock and other plants and plant products; to enable the Secretary of Agriculture to establish and maintain quarantine districts for plant diseases and insect pests; to permit and regulate the movement of fruits, plants, and vegetables therefrom, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That it shall be unlawful for any person to import or offer for entry into the United States any nursery stock unless and until a permit shall have been issued therefor by the Secretary of Agriculture, under such conditions and regulations as the said Secretary of Agriculture may prescribe, and unless such nursery stock shall be accompanied by a certificate of inspection, in manner and form as required by the Secretary of Agriculture, of the proper official of the country from which the importation is made, to the effect that the stock has been thoroughly inspected and is believed to be free from injurious plant diseases and insect pests: *Provided,* That the Secretary of Agriculture shall issue the permit for any particular importation of nursery stock when the conditions and regulations as prescribed in this act shall have been complied with: *Provided further,* That nursery stock may be imported for experimental or scientific purposes by the Department of Agriculture upon such conditions and under such regulations as the said Secretary of Agriculture may prescribe: *And provided further,* That nursery stock imported from countries where no official system of inspection for such stock is maintained may be admitted upon such conditions and under such regulations as the Secretary of Agriculture may prescribe.

Sec. 2. That it shall be the duty of the Secretary of the Treasury promptly to notify the Secretary of Agriculture of the arrival of any nursery stock at port of entry; that the person receiving such stock at port of entry shall, immediately upon entry and before such stock is delivered for shipment or removed from the port of entry, advise the Secretary of Agriculture or, at his direction, the proper State, Territorial, or District official of the State or Territory or the District to which such nursery stock is destined, or both, as the Secretary of Agriculture may elect, of the name and address of the consignee, the nature and quantity of the stock it is proposed to ship, and the country and locality where the same was grown. That no person shall ship or offer for shipment from one State or Territory or District of the United States into any other State or Territory or District, any nursery stock imported into the United States without notifying the Secretary of Agriculture or, at his direction, the proper State, Territorial, or District official of the State or Territory or District to which such nursery stock is destined, or both, as the Secretary of Agriculture may elect, immediately upon the delivery of the said stock for shipment, of the name and address of the consignee, of the nature and quantity of stock it is proposed to ship, and the country and locality where the same was grown, unless and until such imported stock has been inspected by the proper official of a State, Territory, or District of the United States.

Sec. 3. That no person shall import or offer for entry into the United States any nursery stock unless the case, box, package, crate, bale, or bundle thereof shall be plainly and correctly marked to show the general nature and quantity of the contents, the country and locality where the same was grown, the name and address of the shipper, owner, or person shipping or forwarding the same, and the name and address of the consignee.

Sec. 4. That no person shall ship or deliver for shipment from one State or Territory or District of the United States into any other State or Territory or District any such imported nursery stock the case, box, package, crate, bale, or bundle whereof is not plainly marked so as to show the general nature and quantity of the contents, the name and address of the consignee, and the country and locality where such stock was grown, unless and until such imported stock has been inspected by the proper official of a State, Territory, or District of the United States.

Sec. 5. That whenever the Secretary of Agriculture shall determine that the unrestricted importation of any plants, fruits, vegetables, roots, bulbs, seeds, or other plant products not included by the term "nursery stock" as defined in section six of this act may result in the entry into the United States or any of its Territories or Districts of injurious plant diseases or insect pests, he shall promulgate his determination, specifying the class of plants and plant products the importation of which shall be restricted and the country and locality, where they are grown, and thereafter, and until such promulgation is withdrawn, such plants and plant products imported or offered for import into the United States or any of its Territories or Districts shall be subject to all the provisions of the foregoing sections of this act: *Provided,* That before the Secretary of Agriculture shall promulgate his determination that the unrestricted importation of any plants, fruits, vegetables, roots, bulbs, seeds or other plant products not included by the term "nursery stock" as defined in section six of this act may result in the entry into the United States or any of its Territories or Districts of injurious plant diseases or insect pests he shall, after due notice, give a public hearing, under such rules and regulations as he shall prescribe, at which hearing any interested party may appear and be heard, either in person or by attorney.

Sec. 6. That for the purpose of this act the term "nursery stock" shall include all field-grown florists' stock, trees, shrubs, vines, cuttings, grafts, scions, buds, fruit pits and other seeds of fruit and ornamental trees or shrubs and other plants and plant products for propagation, except field, vegetable, and flower seeds, bedding plants, and other herbaceous plants, bulbs, and roots.

Sec. 7. That whenever, in order to prevent the introduction into the United States of any tree, plant, or fruit disease or of any injurious insect, new to or not theretofore widely prevalent or distributed within and throughout the United States, the Secretary of Agriculture shall determine that it is necessary to forbid the importation into the United States of any class of nursery stock or of any other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products from a country or locality where such disease or insect infestation exists, he shall promulgate such determination, specifying the country and locality and the class of nursery stock or other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products which, in his opinion, should be excluded. Following the promulgation of such determination by the Secretary of Agriculture, and until the withdrawal of the said promulgation by him, the importation of the class of nursery stock or of other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products specified in the said promulgation from the country and locality therein named, regardless of the use for which the same is intended, is hereby prohibited; and until the withdrawal of the said promulgation by the Secretary of Agriculture, and notwithstanding that such class of nursery stock, or other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products be accompanied by a certificate of inspection from the country of importation, no person shall import or offer for entry into the United States from any country or locality specified in such promulgation, any of the class of nursery stock or of other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products named therein, regardless of the use for which the same is intended: *Provided,* That before the Secretary of Agriculture shall promulgate his determination that it is necessary to forbid the importation into the United States of the articles named in this section he shall, after due notice to interested parties, give a public hearing, under such rules and regulations as he shall prescribe, at which hearing any interested party may appear and be heard, either in person or by attorney: *Provided further*, That the quarantine provisions of this section, as applying to the white-pine blister rust, potato wart, and the Mediterranean fruit fly, shall become and be effective upon the passage of this act: *Provided further*, That hereafter any class of nursery stock or of any other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products of which the importation may be forbidden from any country or locality under the provisions of section seven of the Plant Quarantine Act approved August twentieth, nineteen hundred and twelve (Thirty-seventh Statutes, page three hundred and fifteen), may be imported for experimental or scientific purposes by the Department of Agriculture upon such conditions and under such regulations as the said Secretary of Agriculture may prescribe.

SEC. 8. That the Secretary of Agriculture is authorized and directed to quarantine any State, Territory, or District of the United States, or any portion thereof, when he shall determine the fact that a dangerous plant disease or insect infestation, new to or not theretofore widely prevalent or distributed within and throughout the United States, exists in such State or Territory or District; and the Secretary of Agriculture is directed to give notice of the establishment of such quarantine to common carriers doing business in or through such quarantined area, and shall publish in such newspapers in the quarantined area as he shall select notice of the establishment of quarantine. That no person shall ship or offer for shipment to any common carrier, nor shall any common carrier receive for transportation or transport, nor shall any person carry or transport from any quarantined State or Territory or District of the United States, or from any quarantined portion thereof, into or through any other State or Territory or District, any class of nursery stock or any other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products specified in the notice of quarantine except as hereinafter provided. That it shall be unlawful to move or allow to be moved any class of nursery stock or any other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products specified in the notice of quarantine hereinbefore provided, and regardless of the use for which the same is intended, from any quarantined State or Territory or District of the United States, or quarantined portion thereof, into or through any other State of Territory or District, in manner or method or under conditions other than those prescribed by the Secretary of Agriculture. That it shall be the duty of the Secretary of Agriculture to make and promulgate rules and regulations which shall permit and govern the inspection, disinfection, certification, and method and manner of delivery and shipment of the class of nursery stock or of any other class of plants, fruits, vegetables, roots, bulbs, seeds, or other plant products specified in the notice of quarantine hereinbefore provided, and regardless of the use for which the same is intended, from a quarantined State or Territory or District of the United States, or quarantined portion thereof, into or through any other State or Territory or District; and the Secretary of Agriculture shall give notice of such rules and regulations as hereinbefore provided in this section for the notice of the establishment of quarantine: *Provided*, That before the Secretary of Agriculture shall promulgate his determination that it is necessary to quarantine any State, Territory, or District of the United States, or portion thereof, under the authority given in this section, he shall, after due notice to interested parties, give a public hearing under such rules and regulations as he shall prescribe, at which hearing any interested party may appear and be heard, either in person or by attorney.

SEC. 9. That the Secretary of Agriculture shall make and promulgate such rules and regulations as may be necessary for carrying out the purposes of this act.

SEC. 10. That any person who shall violate any of the provisions of this act, or who shall forge, counterfeit, alter, deface, or destroy any certificate provided for in this act or in the regulations of the Secretary of Agriculture, shall be deemed guilty of a misdemeanor and shall, upon conviction thereof, be punished by a fine not exceeding $500 or by imprisonment not exceeding one year, or both such fine and imprisonment, in the discretion of the court: *Provided*, That no common carrier shall be deemed to have violated the provisions of any of the foregoing sections of this act on proof that such carrier did not knowingly receive for transportation or transport nursery stock or other plants or plant products as such from one State, Territory, or District of the United States into or through any other State, Territory, or District; and it shall be the duty of the United States attorneys diligently to prosecute any violations of this act which are brought to their attention by the Secretary of Agriculture or which come to their notice by other means.

SEC. 11. That the word "person" as used in this act shall be construed to import both the plural and the singular, as the case demands, and shall include corporations, companies, societies, and associations. When construing and enforcing the provisions of this act, the act, omission, or failure of any officer, agent, or other person acting for or employed by any corporation, company, society, or association, within the scope of his employment or office, shall in every case be also deemed to be the act, omission, or failure of such corporation, company, society, or association as well as that of the person.

SEC. 12. That for the purpose of carrying out the provisions of this act there shall be appointed by the Secretary of Agriculture from existing bureaus and offices in the Department of Agriculture, including the Bureau of Entomology, the Bureau of Plant Industry, and the Forest Service, a Federal Horticultural Board consisting of five members, of whom not more than two shall be appointed from any one bureau or office, and who shall serve without additional compensation.

SEC. 13. That there is hereby appropriated, out of the moneys in the Treasury not otherwise appropriated, to be expended as the Secretary of Agriculture may direct, for the purposes and objects of this act, the sum of $25,000.

SEC. 14. That this act shall become and be effective from and after the first day of October, nineteen hundred and twelve, except as herein otherwise provided.

THE NEW YORK LAW TO REGULATE THE SALE OF FRUIT-BEARING TREES (April 15, 1914).

Section 1. The title of article eleven of chapter nine of the laws of nineteen hundred and nine, entitled "An act in relation to agriculture, constituting chapter one of the consolidated laws," is hereby amended to read as follows:

Apples; pears; peaches; quinces; fruit-bearing trees.

§ 2. Such chapter is hereby amended by adding at the end of article eleven three new sections to be sections two hundred and sixty-three, two hundred and sixty-four and two hundred and sixty-five, to read, respectively, as follows:

§ 263. *Sale of fruit-bearing trees.* Every person, firm or corporation selling fruit-bearing trees shipped from any point in the state of New York must have attached to each car, box, bale or package a copy of a certificate of inspection issued by the state department of agriculture and signed by the commissioner of agriculture, valid to the first day of September next following the date of issuance thereof. There shall also be attached to each bundle or package of such fruit-bearing trees a label specifying the name of variety of trees contained therein. In case such bundle or package shall contain trees of different kinds or varieties there must be attached to each tree therein a like label.

§ 264. *Damages accruing from sale of trees.* Nothing contained in section two hundred and sixty-three or any other section of this chapter shall be construed to deprive a purchaser of any fruit-bearing tree of his remedy at law in a civil action to recover damages sustained by reason of such trees proving untrue to name as specified on the label. Such damages may be recovered in a civil action by the purchaser of such fruit-bearing trees or by his personal representative or assignee at any time prior to the third bearing year, provided the purchaser notifies the seller as soon as he has reason to believe that such trees are not true to name. In any action to recover damages suffered by the purchaser by reason of any fruit tree or trees not being of the name or variety under which they were tagged and sold, the seller shall have the burden of proof in establishing that any contract not in writing or any provision of any such contract exempting the seller from liability or limiting his liability was fully understood and agreed to by the purchaser. In every case of a sale of fruit-bearing trees in lots of twenty-five or more, when by written contract, the seller must at once furnish the purchaser a copy of such contract upon the face of which shall be plainly printed the following: "In any action to recover damages suffered by the purchaser by reason of any fruit tree or trees not being of the name or variety under which they were tagged and sold, the seller shall have the burden of proof in establishing that any contract not in writing or any provision of any such contract exempting the seller from liability or limiting his liability was fully understood and agreed to by the purchaser." The seller must also accompany the shipment of such trees with an itemized list of the same, which lists shall also give the name of the county and state where the trees covered by it were grown, the age of the trees, and the name and address of the person for whom the trees were grown, if requested by letter or in writing on the contract by the purchaser at the time of purchase. Within five days after the receipt by the purchaser of the trees and the list thereof the purchaser shall compare and notify the seller of any discrepancy between the list and the labels on such trees.

§ 265. *Agent to carry certificate of authority.* Any person, firm or corporation acting as agent for another in the sale of fruit-bearing trees in this state shall carry with him, at all times when engaged in selling trees, a certificate in writing signed by his principal and properly acknowledged, showing his authority to act as such agent and upon request shall exhibit the same to the purchaser and shall leave with the purchaser a copy of the contract bearing on its face the clause referred to in section two hundred and sixty-four.

§ 3. This act shall take effect September first, nineteen hundred and fourteen.

THE HORTICULTURAL QUARANTINE LAW OF CALIFORNIA.

AN ACT to provide for the protection of horticulture and to prevent the introduction into this state of insects or diseases, or animals, injurious to fruit or fruit trees, vines, bushes or vegetables, providing for a quarantine for the enforcement of this act, making a violation of the terms of the act a misdemeanor, and providing the penalty therefor; providing that said act shall be an urgency measure and go into effect immediately, and repealing that certain act entitled "An act for the protection of horticulture and to prevent the introduction into this state of insects, or diseases, or animals, injurious to fruit or fruit trees, vines, bushes or vegetables, and to provide for a quarantine for the enforcement of this act," approved March 11, 1899.

The people of the State of California do enact as follows:

SECTION 1. Any person, persons, firm or corporation who shall receive, bring or cause to be brought into the State of California, any nursery stock, trees, shrubs, plants, vines, cuttings, grafts, scions, buds or fruit pits, or fruit or vegetables, or seed, shall immediately after the arrival thereof notify the state commissioner of horticulture, or deputy quarantine officer, or quarantine guardian of the district or county in which such nursery stock, or fruit or vegetables or seed are received, of their arrival, and hold the same without unnecessarily moving the same, or placing such articles where they may be harmful, for the immediate inspection of such state commissioner of horticulture, or deputy quarantine officer or guardian. If there is no quarantine guardian or state horticultural quarantine officer in the county where such nursery stock or fruit or vegetable, or seed is received, it shall then be the duty of such person, persons, firm or corporation to notify the state commissioner of horticulture, who shall make immediate arrangements for their inspection. The state commissioner of horticulture, deputy quarantine officer, quarantine guardian or such person or persons as shall be commissioned by the state commissioner of horticulture to make such inspection, or to represent said commissioner, is hereby authorized and empowered to enter at any time into any car, warehouse, depot or upon any ship within the boundaries of the State of California whether in the stream or at the dock, wharf, mole, or any other place where such nursery stock or fruit or vegetables or seed or other described articles are received or in which such nursery stock or fruit or vegetables or seed is imported into the state, for the purpose of making the investigation or examination to ascertain whether such nursery stock, trees, shrubs, plants, vines, cuttings, grafts, scions, buds, fruit pits, fruit, vegetables or seed is infested with any species of injurious insects, or their eggs, larvæ or pupæ or other animal or plant disease.

If after such examination or inspection, any of the said described articles are found to be so infested or infected as aforesaid, then it shall be the duty of the owner, owners, or persons, firm or corporation having charge or possession thereof to so disinfect at his or their expense such portion or portions of the ship, dock, wharf, mole, car, warehouse or depot where said articles may have been located in such a manner as to destroy all infection or infestation present or that is liable to be present, and all articles or packages or soils apt to be so infested or infected shall be held until the said articles or packages or soils have been thoroughly disinfected and all injurious insects, or their eggs, larvæ or pupæ or other animal or plant disease have been eradicated and destroyed; *provided, however*, that all articles of nursery stock, trees, shrubs, plants, vines, cuttings, grafts, scions, buds, fruit pits, fruits, vegetables or seed which are infested or infected with such species of injurious insects or their eggs, larvæ or pupæ or other animal or plant disease which may be or be liable to be injurious to the orchards, vineyards, gardens or farms within said state, shall be destroyed or reshipped out of the state as hereinafter provided. The said officer so making such inspection shall not permit any of the described articles so coming in contact with said infested or infected articles or any articles which might convey infection or infestation to be removed or taken from any such car, warehouse, depot, ship, dock, wharf or any other place until after such infection or infestation shall have been destroyed.

Sec. 2. Each carload, case, box, package, crate, bale or bundle of trees, shrubs, plants, vines, cuttings, grafts, scions, buds, fruit pits, or fruit or vegetables or seed, imported or brought into this state, shall have plainly and legibly marked thereon in a conspicuous manner and place the name and address of the shipper, owner, or owners or person forwarding or shipping the same, and also the name of the person, firm or corporation to whom the same is forwarded or shipped, or his or its responsible agents, also the name of the country, state or territory where the contents were grown and a statement of the contents therein.

Sec. 3. When any shipment of nursery stock, trees, vines, plants, shrubs, cuttings, grafts, scions, buds, fruit pits or seed or vegetables or fruit, imported or brought into this state, is found infested or infected with any species of injurious insects, or their eggs, larvæ or pupæ or other animal or plant disease or there is reasonable cause to presume that they may be so infested or infected, which would cause damage, or be liable to cause damage, to the orchards, vineyards, gardens or farms of the State of California, or which would be or be liable to be detrimental thereto or to any portion of said state, or to any of the orchards, vineyards, gardens or farms within said state such shipment shall be immediately destroyed by the state commissioner of horticulture, his deputy quarantine officer, quarantine guardians or other person or persons, who shall be commissioned by the state commissioner of horticulture to make such inspection; *provided, however*, that if the nature of the injurious insects, or their eggs, larvæ, pupæ or animal or plant disease be such that no damage or detriment can be caused to the said orchards, vineyards, gardens or farms of California or any of the same by the shipment of the same out of the state, then the said state commissioner of horticulture, his deputy quarantine officer, quarantine guardians or other person or persons who shall be commissioned by the state commissioner of horticulture to make such inspection, and who shall make such inspection, shall notify the owner or person, firm or corporation having possession or control of said articles to ship the same out of the state within forty-eight hours after such notification, and it shall be the duty of such owner or owners, or person, firm or corporation, to so ship said articles, but such shipment shall be under the sole direction and control of the officer so making the inspection and shall be at the expense of the owner or owners, his or their agent or agents, and for a failure to comply with such notice such owner or owners, his or their agent or agents shall be deemed guilty of a violation of the terms of this act and be punished accordingly and immediately after the expiration of the time specified in said notice said articles shall be seized and destroyed by said officer at the expense of the said owner or owners, his or their agent or agents.

Sec. 4. When any shipment of nursery stock, trees, vines, plants, shrubs, cuttings, grafts, scions, fruit, fruit pits, vegetables or seed, or any other horticultural or agricultural product passing through any portion of the State of California in transit, is infested or infected with any species of injurious insects, their eggs, larvæ or pupæ or animal or plant disease, which would cause damage, or be liable to cause damage to the orchards, vineyards, gardens or farms of the State of California, or which would be, or be liable to be, detrimental thereto or to any portion of said state, or to any of the orchards, vineyards, gardens or farms within said state, and there exists danger of dissemination of such insects or disease while such shipment is in transit in the State of California, then such shipment shall be placed within sealed containers, composed of metallic or other material, so that the same can not be broken or opened, or be liable to be broken or opened, so as to permit any of the said shipment, insects, their eggs, larvæ or pupæ or animal or plant disease to escape from such sealed containers and the said containers shall not be opened while within the State of California.

Sec. 5. No person, persons, firm or corporation shall bring or cause to be brought into the State of California any fruit or vegetable or host plant which is now known to be, or hereafter may become a host plant or host fruit of any species of the fruit fly family *Trypetidæ* from any country, state or district where such species of *Trypetidæ* is known to exist and any such fruit, vegetable, or host plant, together with the container and packing, shall be refused entry and shall be immediately destroyed at the expense of the owner, owners or agents.

Sec. 6. No person, persons, firm or corporation shall bring or cause to be brought into the State of California any peach, nectarine, or apricot tree or cuttings, grafts, scions, buds or pits of such trees, or any trees budded or grafted upon peach stock or roots that have been in a district where the disease known as "peach yellows" or the contagious disease known as "contagious peach rosette" are known to exist, and any such attempting to land or enter shall be refused entry and shall be destroyed or returned to the point of shipment at the option of the owner, owners or agent, and at his or their expense.

Sec. 7. No person, persons, firm or corporation shall bring or cause to be brought into the State of California any injurious animals known as English or Australian wild rabbit, flying fox, mongoose or any other animal or animals detrimental to horticultural or agricultural interests.

Sec. 8. Any person, persons, firm or corporation violating any of the provisions of this act shall be guilty of a misdemeanor and shall be punished by imprisonment in the county jail for a period not exceeding six months, or by a fine not exceeding five hundred dollars, or by both such fine and imprisonment.

Sec. 9. It is hereby determined and declared that this act and each and all of the provisions thereof, constitute and is an urgency measure necessary for the immediate preservation of the public safety and health. The facts constituting such necessity are as follows: There now exists in various islands and territory in close proximity to the State of California dangerous and injurious fruit and plant diseases and insects and animals, and heretofore fruits, vegetables, plants, seeds and other articles of horticulture and agriculture from said islands and territory have been and now are being shipped and brought into the State of California, which are to a large extent infested and infected with dangerous and injurious fruit and plant diseases and insects, their eggs, larvæ and pupæ, and which if continued to be brought into the state will cause great danger to the public health, and will greatly damage the horticultural and agricultural interests of said state, and will also be detrimental to the public health, and this act is necessary to provide ample power to prevent the introduction of such insects and diseases and injurious animals into the state and to prevent the spread of such disease, insects and animals.

Sec. 10. That certain act entitled "An act for the protection of horticulture, and to prevent the introduction into this state of insects, or diseases, or animals, injurious to fruit or fruit trees, vines, bushes, or vegetables, and to provide for a quarantine for the enforcement of this act," approved March 11, 1899, is hereby repealed.

Sec. 11. This act, being an urgency measure as above set forth, shall take effect and be in full force immediately from and after its passage.

Extracts from the Sanders Bill (see page 1650).

2. There is hereby created a board which shall be known as the "Horticultural Inspection Board" of (State), hereinafter called the Board, consisting of three (five) members, two (four) members of which shall be ex-officio members. The third (fifth) member shall be appointed by the Governor for a term of four years. Such third (fifth) member shall be a nursery man actively engaged in the growing of nursery stock. The members of said board shall serve without compensation, but shall receive their actual and necessary traveling expenses incurred in the discharge of their official duties within the provisions of (this act) (sections —— to ——, inclusive). This board is hereby vested with all powers necessary to carry out the provisions of (this act) (sections —— to ——, inclusive.)

Appointment.

3. The Board shall appoint some person qualified by scientific training and practical experience to be state nursery (and orchard) inspector, hereinafter called the inspector, who shall strictly enforce the provisions of (this act) (sections —— to ——, inclusive) as a police regulation of the (state) (commonwealth) under the direction and control of the Board.

Appointment of deputies.

5. The Board is hereby authorized to appoint on the recommendation of the inspector (deputies) (county horticultural inspectors) (district horticultural inspectors) who shall strictly enforce the provisions of (this act) (sections —— to ——,

inclusive) under the direction of the inspector, and they are hereby endowed with the same police power as the state inspector, and shall be furnished with official badges or other insignia of authority, which shall be carried while on duty.

6. The Board (State Horticultural Commission) shall have the power to prescribe, modify and enforce such reasonable rules, regulations and orders as may be needed to carry out the provisions of this act, and may publish an annual report describing the various phases of the inspection work, or may publish such other information as may seem desirable concerning the inspection and such insects and diseases as are covered by (this act) (Sections —— to ——, inclusive). Such rules and regulations to be printed from time to time and furnished free to interested parties.

Inspector's duties and powers.

7. The inspector or his deputies shall at least once each year inspect all nurseries and other places in which nursery stock is kept for sale in the state. For this purpose such state inspector or his deputies shall have free access, within reasonable hours, to any field, orchard, garden, packing ground, building, cellar, freight, or express office, warehouse, car, vessel, or other place, which it may be necessary or desirable for him to enter in carrying out the provisions of this act. It shall be unlawful to deny such access to the inspector or his deputies or to hinder, thwart or defeat such inspection by misrepresentation or concealment of facts or conditions or otherwise.

8. The inspector or his deputies shall have the authority to inspect any orchard, fruit or garden plantation, park, cemetery, private premises, public place, and any place which might become infested or infected with dangerous or harmful insects or plant diseases. He shall also have the authority to inspect or reinspect at any time or place any nursery stock shipped in or into the state and to treat it as hereinafter provided.

Diseased plant material on premises.

9. The inspector with the approval of the Board (State Horticultural Commission) is hereby empowered to prohibit and prevent the removal or shipment or transportation of plant material and any other material from any private or public property, or property owned or controlled by the state, or any area of the state (commonwealth) which in his judgment contains dangerously infested or infected nursery stock or plant or other material of any kind for such periods and under such conditions as in his judgment seems necessary in order to prevent the further spread of the infestation or infection, giving such notice thereof as may be prescribed by the Board; and during the existence of such order no person shall remove or ship from such area any such material whatsoever, except by special permission or direction (certificate) of the inspector.

10. It shall be unlawful for any person in this state knowingly to permit any dangerous insect or plant disease to exist in or on his premises. It shall also be unlawful to sell or offer for sale any stock infested or infected with such insect or disease.

11. In case the inspector or his deputy shall find present on any nursery or dealer's premises or any packing ground or in any cellar or building used for storage or sale of nursery stock any injurious insect or plant disease, he shall notify the owner or person having charge of the premises in writing to that effect, and shall withhold his certificate hereinafter provided for, until the premises are freed from such injurious insect or plant disease, as hereinafter provided. It shall be unlawful for any person after receiving such notice to ship or deliver or cause to be shipped or delivered any nursery stock from such aforesaid premises.

12. (1) If the inspector or his deputy shall find on examination any nursery, orchard, small fruit plantation, park, cemetery, or any private or public premises infested with injurious insects or plant diseases, he shall notify the owner or person having charge of such premises to that effect, and the owner or person having charge of the premises shall within ten days after such notice cause the removal and destruction of such trees, plants, shrubs or other plant material if incapable of successful treatment; otherwise, cause them to be treated as the inspector may direct. No damages shall be awarded to the owner for the loss of infested or infected trees, plants shrubs or other plant material under this act.

(2) In case the owner or person in charge of such premises shall refuse or neglect to carry out the orders of the inspector within ten days after receiving written notice, the inspector may proceed to treat or destroy the infested or infected plants or plant material. The expense thereof shall be assessed collected and enforced as taxes are assessed collected and enforced against the premises upon which such expense was incurred. The amount of such expense when collected shall be paid to and become a part of the fund used to enforce the provisions of (this act) (sections —— to ——, inclusive).

Imported stock.

14. Every person receiving directly or indirectly any nursery stock from foreign countries shall notify the (state) (county) (district) inspector of the arrival of such shipment, the contents thereof and the name of the consignor; and shall hold such shipment unopened until duly inspected or released by the inspector. In case any infested or infected stock is discovered in such shipment, the shipment shall be subject to the provisions of (this act) (sections —— to ——, inclusive).

Nursery certificate.

15. (1) The inspector shall cause to be issued to owners of any nursery in the state after the stock has been officially inspected as previously provided, and found to be apparently free from injurious insects or plant diseases, a certificate setting forth the fact of such inspection and the number of acres or fraction thereof inspected. Said certificate shall be valid not to exceed one year from (month) 1st.

(2) It shall be unlawful for any person to sell, to offer for sale or to remove or ship from a nursery or other premises, any nursery stock unless such stock has been officially inspected and a certificate or permit has been granted by the inspector.

Dealer's certificate.

16. All dealers within the meaning of this act, located either within or without the state, engaged in selling nursery stock in this state or soliciting orders for nursery stock within this state, shall secure a dealer's certificate by furnishing a sworn affidavit that he will buy and sell only stock which has been duly inspected and certified by an official state inspector; and that he will maintain with the inspector a list of all sources from which he secures his stock.

Agent's certificate.

18. All agents within the meaning of this act selling nursery stock or soliciting orders for nursery stock for any nurseryman or dealer located within the state or outside the state, shall be required to secure and carry an agent's certificate bearing a copy of the certificate held by the principal. Said agent's certificate shall be issued only by the (State) inspector to agents authorized by their principal or upon request of their principal. Names and addresses of such agents shall not be divulged by the inspector or the board.

19. The inspector shall at any time have the power to revoke any certificate for sufficient cause, including any violation of (this act) (sections —— to ——, inclusive) or non-conformity with any rule or regulation promulgated under (this act) (sections —— to ——, inclusive).

ÍNULA (ancient name). *Compósitæ.* Hardy herbaceous plants of the easiest culture and of rather coarse habit, with heads of yellow or orange, each 2 to 4 inches across, borne in summer.

Herbs, usually perennial, glandular, hairy: lvs. radical or alternate, entire or serrate: heads large, medium or small, solitary, corymbose, panicled or crowded at the crown; fls. tubular and ray, the rays yellow, rarely white; disk-fls. perfect, their tubular corollas 5-toothed: achenes 4–5-ribbed.—A genus of about 56 species, found in Eu., Asia and Afr. None of its near allies is cult.

There is such a great abundance of autumn-flowering yellow composites in the hardy border that only those inulas that bloom in early summer are particularly desirable. Elecampane, *I. Helenium*, is probably also cultivated for medicine. A preparation of the mucilaginous roots is common in drugstores. Inula flowers have as many as forty linear rays. The plants like a sunny position, grow vigorously in any garden soil, and are propagated by division or seed.

A. *Sts. panicled or corymbose.*

Helènium, Linn. ELECAMPANE. Fig. 1959. Tall, thick-stemmed: lvs. unequally dentate-serrate; root-lvs. elliptic-oblong, narrowed into a petiole; st.-lvs. half-clasping, cordate-oblong: outer involucral parts leafy, ovate. Wet, sandy and mountainous regions. Eu., N. Asia. Naturalized in Amer.—The roots are thick and carrot-like. For medicinal purposes, 2-year-old roots should be dug in Aug. If older, they are likely to be stringy and woody.

AA. *Sts. 1-fld., or with at most 2 or 3 heads.*

B. *Outer involucral parts linear and numerous.*

C. *Plants 2½ ft. tall or more.*

grandiflòra, Willd. Height 3–4 ft., the st. simple and hairy: lvs. elliptic-oblong, serrulate, all sessile; upper ones subcordate; lower ones 2–4 in. long: glands numerous: heads 3¼–4 in. across. Himalayas, Caucasus. G.F. 6:406.—Earliest blooming inula in cult. Bears orange-yellow fls. 5 in. across in June, and has bold but not coarse habit.

glandulòsa, Willd. Height 2½–4 ft.: lower lvs. oblong-spatulate, long-attenuate at the base, the uppermost oblong with a subcordate-decurrent base, all entire or very obsoletely denticulate: glands remote;

scale of involucre lance-shaped and hairy. Caucasus. B.R. 334. B.M. 1907. Gn. 22. p. 234; 25, p. 101; 49:6 and p. 7. J.H. III. 35:153; 63:139. R.H. 1881, p. 419. G.M. 33:541; 38:477. G. 5:337; 7:649, 651. Var. **laciniàta**, Hort., seems to be a trade name for the fimbriate form figured in G.M. 46:625.—Keller says it has deep golden-yellow, fringed, half-drooping rays. Rays are commonly said to be entire, but B.M. 1907 shows 2 minute teeth, and in B.R. 334 the fringes are more than ¼in. long. This is said to be the only cult. species that does not seed freely. The Garden pictures an orange variety.

CC. *Plants 2 ft. or less tall.*

Hoòkeri, C. B. Clarke. Height 1–2 ft., usually very shaggy above: lvs. 3–5 in. long, sessile or narrowed into very short petioles, oblong-lanceolate, acute at the base, minutely toothed, glandular: heads 1½–2½ in. across; rays "pale yellow," according to Hooker. Himalayas. B.M. 6411 (rays pure yellow).—Fls. orange-yellow, according to J. W. Manning. It is said to flower in Aug. and Sept., and has bright yellow fringed rays. However, in B.M. 6411 the rays have only 3 minute teeth.

1959. Inula Helenium. (×⅓)

británnica, Linn. A hairy perennial usually not over 18 in. high, with a simple st. and lanceolate slightly toothed lvs.: fls. lemon-yellow, the bracts linear and very numerous. June–Aug. Eu. and Asia.—Useful for its early bloom and small stature.

BB. *Outer involucral parts lanceolate and leafy.*

hírta, Linn. St. 12–15 in. high, simple: lvs. netted-veined, lanceolate or ovate-oblong, the lowest narrowed at the base, the others rounded at the base and half-clasping, all entire or finely ciliate. Eu., N. Asia.—Fls. July–Aug.

ensifòlia, Linn. (*I. bubònium,* Hort.). St. about 2 ft., simple: lvs. with numerous somewhat parallel nerves, narrowly linear-lanceolate: fls. large, yellow, the involucral parts appressed, not spreading. Eu., N. Asia. G.M. 41:559.—July, Aug. Rockery plant; blooms first year from seed if sown early.

Royleàna, DC. A striking, large-fld. elecampane with orange-yellow petals: st. unbranched, bearing numerous ovate, slightly toothed, hairy lvs. which are narrowed at the base into winged petioles: fls. very numerous in each head, showy; buds conspicuous, black. Himalayan region. F.S.R. 1:310. G.C. III. 38:264. Gn.W. 23:693. G. 30:117.—Suitable for somewhat protected places.

AAA. *Sts. racemosely clustered.*

racemòsa, Hook. f. A tall stout perennial, 1–5 ft., with a grooved st. and leathery lvs. 8–18 in. long: heads numerous, 1½–2 in. across, showy, the outer bracts with recurved tips. Himalayas.—Little known in Amer. and perhaps not hardy.

I. Óculus-Chrísti, Linn. Two ft.; an erect, somewhat branched, woolly perennial with oblong hairy lvs.: fls. yellow, the rays twice longer than the involucral bracts. Sold in England, but apparently unknown in Amer.

N. TAYLOR.†

IOCHRÒMA (Greek, *violet-colored*). *Solanàceæ.* Flowering shrubs cultivated outdoors in California and under glass in Europe.

In the wild, shrubs or small trees; spineless, glabrous or mostly stellate-tomentose: lvs. entire, often large: fls. purple, blue, scarlet, yellow or white, in clusters or on twin pedicels; corolla long-tubular or narrow-trumpet-shaped, with 5 short or very small lobes, the throat more or less closed by appendages or folds; stamens inserted in the tube, included or exserted; disk present or absent; ovary 2-celled: fr. a pulpy berry.—Species about 20, mostly in W. Trop. S. Amer.

A. *Fls. blue.*

lanceolàtum, Miers. Shrub, 4–8 ft. high, the young branches downy with stellate hairs: lvs. alternate, oval or elliptic-lanceolate, acute, entire, tapering below into a long petiole: umbels supra-axillary and terminal; fls. rich deep purple-blue; corolla-tube slightly curved, somewhat puberulent, the margin shortly unequally 5-lobed or -toothed and pubescent. Ecuador. B.M. 4338 and F.S. 4:309 (as *Chænestes lanceolata*).—Seedlings are said to vary in shades of violet or purple.

tubulòsum, Benth. Shrub, 4–6 ft., the sts. and lvs. pubescent or hairy: lvs. stalked, ovate, attenuate at base and acute or somewhat abruptly acuminate at apex: fls. deep blue, as many as 20 sometimes hanging in a graceful cluster; corolla about 1½ in. long, tubular, the brief margin or limb 5-toothed. Colombia. B.R. 31:20. F.S. 1:131.

grandiflòrum, Benth. (*I. Warscewíczii,* Regel). Handsome shrub, with terete pubescent branches: lvs. broadly ovate, rounded at base and acuminate at apex, pubescent above and paler beneath: fls. in a simple peduncled terminal several-fld. pendulous cyme, large and rich purple; corolla funnelform, the tube long and pubescent, the throat flaring or campanulate and the large limb with 5 triangular spreading-recurved lobes; filaments included, glabrous. Ecuador. B.M. 5301. F.S. 11:1163. H.F. II. 5:102. Gt. 4:130.—The *I. purpureum* of trade-lists may belong here.

AA. *Fls. scarlet, orange-scarlet or yellow (to white in cult.).*

fuchsioìdes, Miers. Shrub, glabrous or nearly so: lvs. often clustered, obovate to oval or oblong, very obtuse, tapering at the base into a short petiole: fls. more or less clustered, orange-scarlet, drooping; corolla thrice exceeding the 5-toothed and bursting calyx, the tube long-cylindrical and nearly straight, the limb 5-angled and with intermediate teeth; filaments included, downy at the base. Peru. B.M. 4149 and F.S. 1:157 (both as *Lycium fuchsioides*).—A white-fld. form is also offered.

flàvum, André. Bushy shrub, 6 or 7 ft., the young growth glabrous: lvs. alternate and stalked, oval-lanceolate, short-pubescent beneath, attenuate at both ends: fls. pale yellow, in drooping axillary clusters, tubular, 1½ in. long, the border or limb short-toothed. Colombia. R.H. 1898:360.

coccíneum, Scheidw. Shrubby, the branches pubescent: lvs. stalked, oblong, undulate and somewhat repand, long-acuminate, hairy on nerves and veins: fls. in an umbel-like fascicle, drooping, scarlet; corolla long-tubular, about 2 in. long, with a narrow border or limb; calyx about ¼in. long, broadly short-toothed. Cent. Amer. F.S. 12:1261.

L. H. B.

IÒNE (one of the nereids). *Orchidàceæ.* About a half-dozen pseudobulbous orchids of E. India, by some united with Bulbophyllum: lateral sepals usually connate and under the lip, the latter rather large, straight and rigid; pollinia 4, attached in pairs to 2 glands. *I. paleàcea,* Lindl. (*Bulbophýllum paleàceum,* Benth.), has drooping fls. about 1 in. long, many in erect spikes; sepals greenish with pink nerves; petals spreading, broadly oblong and 1–3-nerved; lip ovate-lanceolate: scape exceeding the lf., about 9 in. India. B.M. 6344. *I. siaménsis,* Rolfe. Pseudobulbs 1-lvd., 4-angled-ovoid: lvs. narrow-oblong, about 3 in. long: scapes nearly erect, slender, about 6 in. long, bearing a raceme about 2½ in. long that has 9–10 fls., which are about ⅓in. long, pale green with dull purple on lateral sepals and lip and with purple dots near margin of outer segms. Siam. Recent. *I. grandiflòra,* Rolfe. Pseudobulbs 1-lvd., ovoid: lvs. oblong, 2 in. or less long: scapes erect, 1-fld.; fl. dull lurid purple; sepals and petals oblong, acute; lip cordate-ovate, hirsute above, keeled beneath. Burma. Recent.

L. H. B.

IONÍDIUM CONCOLOR: *Hybanthus.*

IONOPSÍDIUM (Greek, *violet-like*). *Crucíferæ.* One pretty, tufted little plant, growing 2 or 3 in. high and bearing numerous small 4-petaled, lilac fls. from spring to fall. It is a half-hardy perennial from Portugal and N. Afr., but is treated as an annual. It is desirable for edgings in moist shady places, and for rockeries; also as a pot subject in window-gardening. In rich garden soil the plants make numerous runners. The fls. are about ½in. across, 1 on each stalk. They open white and turn lilac. The plant has been advertised as the diamond flower. This plant is referred by some to Cochlearia, a genus whose limits are very uncertain.

acaùle, Reichb. (*Cochleària acaùlis,* Desf.). Lvs. ovate-rotund, heart-shaped at the base; petioles proportionately very long: pods subrotund, notched. B.R. 32:51. Gn. 71, p. 90; 72, p. 398.—Summer to winter.

Wilhelm Miller.

IONÓPSIS (Greek, *violet-like*). *Orchidàceæ.* A small group of epiphytic orchids, numbering about ten species, many of which can probably be reduced to varieties of a few species. Most of the species are insignificant, only one or two being cultivated.

Tropical herbs without pseudobulbs, having very short sts., with few, narrow, sheathing, coriaceous lvs.: sepals subequal, erect, spreading, the dorsal one free, the lateral ones united into a short spur behind; petals like the dorsal sepals; labellum united to the base of the column, middle lobe large, expanded, 2–3 times as long as the sepals, 2-lobed; column short; pollinia 2; fls. small, in simple racemes or much-branched panicles. The fine specimen of *I. paniculata* figured in the Botanical Magazine has a panicle 10 in. long, 8½in. wide, with 5 branches, and about 80 fls., each ¾in. across and chiefly white, with violet markings near the center and a dash of yellow. In its native country it is said to remain in attractive condition from Sept. to May. The fls. are produced so freely and over so long a period that it is sometimes necessary to destroy the fl.-spikes, which are out of all proportion to the number of lvs. The plants succeed in the warmhouse under the same treatment as rodriguezias or the more delicate oncidiums.

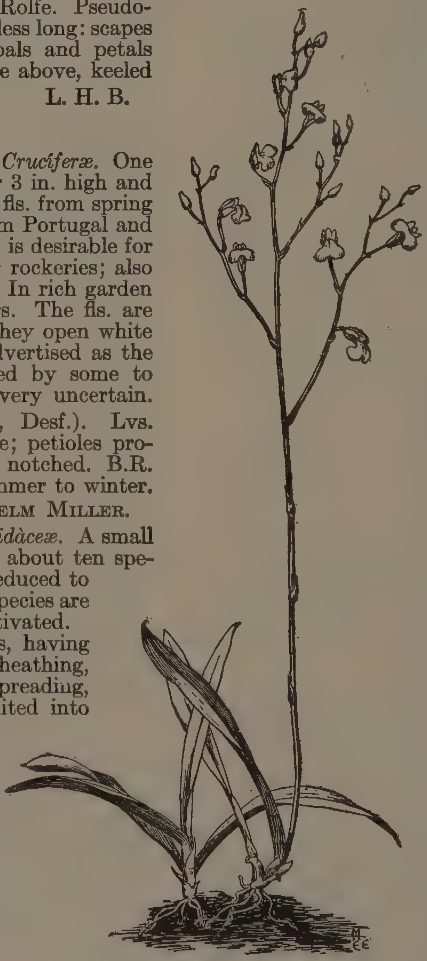
The best means of culture for the successful growing of these beautiful though delicate orchids is in shallow pans with plenty of small broken coal cinders for drainage, covered with the fine particles of fern root and chopped sphagnum gathered from the upland meadows. Plenty of heat and moisture during the growing season are essential. Rest them in winter at a temperature of 50° to 55° F. (Wm. Mathews.)

paniculàta, Lindl. Lvs. thick and channelled, linear-lanceolate, keeled, 2–3 in a cluster and about 6 in. long: panicle much branched and spreading, loaded with innumerable fls. of a delicate texture; sepals and petals very short, sharp-pointed, the petals wider; labellum very large, pubescent at base, with a 2-lobed rounded limb, which in some is almost entirely white, while in others it has a spot of purple or yellow on the disk. Winter. Brazil. B.M. 5541. F.S. 22:2333. A.F. 6:631. C.O. 1.—Very variable.

utricularioìdes, Lindl. Fig. 1960. Lvs. and general habit as in the last: sepals and petals bluntish; spur short; labellum almost twice as long as the petals; lobes subquadrate-rounded, white, streaked with red veins. Jamaica.

I. testiculàta, Lindl. Lvs. tufted, terete, acuminate: fls. whitish, small, numerous. Jamaica.

Heinrich Hasselbring.



1960. Ionopsis utricularioides. (×⅓)

IPECAC. The root of *Cephaëlis Ipecacuanha* (Vol. I, p. 714), a Brazilian plant not cultivated in North America. For wild or American ipecac, see *Gillenia stipulacea.*

IPOMŒA (according to Linnæus from *ips,* bindweed, and *homoios,* like, because of its resemblance to Convolvulus; but ips is a worm). Including *Batàtas, Operculìna,* and *Phárbitis. Convolvulàceæ.* Morning-Glory. Moonflower. Annual or perennial herbs, mostly twining, rarely trees (G.F. 7:364) or shrubs, widely distributed in tropical and temperate regions. They are remarkable for easy culture, quick growth and beautiful flowers; hence the genus includes several of our most popular plants for covering verandas and screening unsightly objects.

The generic characters of Ipomœa are not clearly defined. It is distinguished from Convolvulus by having but 1 capitate or 2–3 globose stigmas, while Convolvulus has 2 linear or ovate stigmas. From Calonyction and Quamoclit it is distinguished by its funnelform corolla-tube and the stamens usually included. St. mostly slender, twining or climbing,

LVIII. One of the many beautiful garden irises.

sometimes prostrate, diffuse or erect: lvs. alternate, entire, lobed or parted, often varying greatly on the same plant: fls. usually showy, borne singly or in cymes on axillary peduncles; corolla funnelform, salverform or bell-shaped (in one species bag-shaped), the limb sometimes entire, but usually 5-angled or 5-lobed (a 5-petalled form of *I. purpurea* occurs as a monstrosity), red, purple, blue, white or yellow, in various shades and mixtures; calyx without the bracts at the base, which appear in some species of Convolvulus, but the outer sepals are commonly larger. The fls. of most species open in early morning and last but a few hours under bright sunlight, hence the popular name. A few open only at nightfall.—Over 400 species of which more than 200 occur in Trop. Amer., chiefly in Mex.

"The Japanese morning-glories," also called "Imperial" and "Emperor" morning-glories, were introduced to the American trade from Japan in 1895. They are probably selected strains of *I. hederacea*, although some botanists consider them to be of hybrid origin, possibly *I. hederacea* × *I. tricolor*. Maximowicz referred them to *I. hederacea*, and this appears to be the more reasonable disposition. The culture of the "asagoa" in Japan amounted to a popular craze about 1830, the equivalent of $14 to $18 sometimes being paid for a single seed of the rare sorts. With political disturbances came a decline of interest, but more recently the popular fancy for morning-glories has again revived. The Japanese gardeners grow their plants almost entirely in pots, and by constant attention have made them vary into many curious oddities in flower and foliage. Several finely illustrated books on the morning-glory alone are published in Japan. See also "Century Magazine," 55:281 (1897). The Japanese ipomeas are sold in this country mostly in strains, each package of seed giving flowers of many forms and colors. There are some inferior strains offered, and the flowers from these are often disappointing; yet as a class the Japanese morning-glories are the most gorgeous and versatile of garden ipomeas. If the seeds are notched they will generally give bloom in six weeks from sowing.

Morning-glories are among the least exacting of garden plants as regards soil and site. Most species love a strong soil and sunny site, with plenty of water; but they will make the best of much that is uncongenial. The seeds of the annual kinds may be sown directly out-of-doors, but are preferably started indoors, at least in the North. If the plants are allowed to become slightly pot-bound before being transplanted, they will come into bloom earlier. Germination may be hastened and also made more certain by filing a small notch in each seed, or by soaking the seeds in warm water about two hours. The "moonflower" and the "Japanese morning-glories" particularly are likely to germinate poorly unless these precautions are taken.

The perennial ipomeas are grown from seeds in some cases, but mostly from cuttings of well-ripened wood, layers, or division of the rootstocks. Some of the greenhouse species, notably *I. Horsfalliæ*, rarely produce seed and are rooted from stem-cuttings with great difficulty. These are often propagated successfully by grafting well-ripened shoots on pieces of their own roots, or the roots of *I. pandurata*. *I. ternata* roots from cuttings more readily, and *I. Learii* and *I. Jalapa* are easily propagated from cuttings.

The rapid growth and dense foliage of most garden ipomeas make them especially valuable for covering arbors, verandas, walls, and for screening unsightly objects. *I. purpurea*, *I. tricolor*, *I. hederacea* are the most popular annual species for this purpose; and *I. Learii*, *I. setosa* and *I. pandurata* are among the best perennials. In the South, the perennials may be carried through the winter outside by cutting off the stems and mulching the roots heavily in the fall; in the North the tubers should be taken up and wintered like dahlias, keeping them perfectly dry in a cool greenhouse or frost-proof cellar. *I. leptophylla* is valuable for very dry soils. *I. Bona-nox* (see *Calonyction aculeatum*) is worthy of a place in every garden.

The tender perennials are seen to advantage when trained to pillars, trellises, or along the roof of a greenhouse. Their roots should be given plenty of room to forage and their tops to spread. *I. Horsfalliæ* and its closely related species, *I. ternata*, are very satisfactory for this purpose. After flowering, the strong shoots should be cut back and the plant rested. Several species, particularly *I. Learii*, *I. tricolor* and *I. hederacea*, make excellent pot-plants if they are kept somewhat pot-bound to induce flowering. The roots of nearly all the perennial species are more or less purgative; particularly *I. Purga*, from which comes the jalap of commerce, *I. Jalapa* and *I. cathartica*. *I. Batatas* is the common sweet potato.

The trade names of ipomeas are endlessly mixed. Thus, *I. mexicana* of the catalogues may be *I. hederacea*, *I. digitata*, *I. Jalapa*, *I. Bona-nox*, *I. Learii* or *I. tricolor;* but is rarely the true *I. mexicana* of Gray. "Moonflower" is often applied indiscriminately to several species of Ipomœa, but it should be restricted to species of Calonyction. It is evident that most of the plants now sold as *I. grandiflora* are forms of *Calonyction aculeatum*. *I. hybrida* is a trade name for strains of *I. purpurea* and *I. tricolor*. The "tree ipomœa" is *I. fistulosa*. The "Japanese" or "Imperial" morning-glories may be referred to *I. hederacea*. Other popular catalogue names are: Double morning-glory is mostly *I. purpurea fl.-pl.;* Brazilian morning-glory is *I. setosa;* hardy or perennial moonflower is *I. pandurata;* Ipomœa, Heavenly Blue, is *I. tricolor*.

KEY TO THE SPECIES.

A. *Plants erect, stout, perennial, shrubby or tree-like.*
  B. *Sts. erect or ascending from a tuberous root.*
    C. *Corolla white or cream-colored: lvs. lanceolate* . . . . **1. longifolia**
    CC. *Corolla purple.*
      D. *Lvs. linear* . . . . **2. leptophylla**
      DD. *Lvs. hastate and toothed* . . . . **3. stans**
  BB. *Sts. subshrubby, 4–10 ft. high: corolla pink-purple* . . . . **4. fistulosa**
  BBB. *Sts. woody, erect: arborescent: corolla white.*
    C. *Foliage more or less densely pubescent; lvs. ovate, cordate* . . . . **5. arborescens**
    CC. *Foliage glabrous; lvs. ovate-lanceolate, rounded or truncate at base*. . **6. Wolcottiana**
AA. *Plants twining, climbing or prostrate.*

B. *Sts. prostrate or creeping, not twining.*
C. *Lf.-blades suborbicular, obcordate or notched at apex: fls. blue or purple*........................ 7. **Pes-capræ**
CC. *Lf.-blades variously lobed or oblong-lanceolate: fls. cream-colored*.... 8. **stolonifera**
BB. *Sts. twining or climbing.*
C. *Sepals herbaceous, often elongated and hairy; ovary and caps. 3-celled, 6-seeded (Pharbitis).*
D. *Lvs. deeply 3–5-lobed*.......... 9. **Lindheimeri**
DD. *Lvs. entire or 3-lobed.*
E. *The sepals merely acute.*
F. *Corolla 1½–2-in. long: lvs. usually entire*.............10. **purpurea**
FF. *Corolla about 1 in. long: lvs. usually 3-lobed*............11. **hirsutula**
EE. *The sepals attenuate or caudate-attenuate.*
F. *The lvs. silvery-canescent or silky: corolla purple*.......12. **mutabilis**
FF. *The lvs. hispid to glabrate, not canescent.*
G. *Tips of sepals linear-attenuate, hispid below, the tips spreading*...............13. **hederacea**
GG. *Tips of sepals long-acuminate, not spreading, appressed pubescent with silvery hairs*...............14. **Learii**
CC. *Sepals thick, rarely subherbaceous and then not elongated.*
D. *Corolla salverform; stamens slightly exserted: st. woody below (Exogonium).*
E. *The corolla scarlet, 1½ in. long: lvs. lobed or entire*......15. **microdactylum**
EE. *The corolla blue or purple, 2½ to 3 in. long*...............16. **Purga**
DD. *Corolla not salverform; stamens rarely if ever exserted (Batatas and Operculina).*
E. *The plants annual: sts. glabrous.*
F. *Lvs. linear or lanceolate, subsessile: fls. small, white*.....17. **angustifolia**
FF. *Lvs. ovate-cordate: fls. large, red, blue, or purple*........18. **tricolor**
EE. *The plants perennial, often with large fleshy or woody roots or rootstocks.*
F. *Lvs. divided to the petiole into 3–9 separate, stalked or sessile lfts.: peduncles equaling or shorter than the petioles.*
G. *Fls. red: lf.-segms. sessile, tapering to both ends, margin wavy*............19. **Horsfalliæ**
GG. *Fls. white: lf.-segms. stalked, not tapering to the ends, margin not wavy*.........20. **ternata**
GGG. *Fls. yellow: lf.-segms. sessile, long-pointed*.........21. **aurea**
FF. *Lvs. deeply divided but not into separate lfts.*
G. *Pedicels thickened and fleshy; sepals accrescent in fr., setaceous; corolla subsalverform, purplish red*...22. **setosa**
GG. *Pedicels not thickened nor sepals accrescent.*
H. *Fls. white: segms. of lvs. much toothed or cut; petioles and sts. hispid*...23. **sinuata**
HH. *Fls. rose-purple: lvs. palmately 5–7-lobed to beyond the middle*........24. **digitata**
FFF. *Lvs. entire, angulate or lobed, not divided.*
G. *Sts., lvs. and peduncles densely hairy: corolla funnelform, its lobes obtuse: lf.-lobes unequal, blunt*....25. **bonariensis**
GG. *Sts. and foliage not hairy.*
H. *The lvs. sagittate, short-petioled: fls. 2–3 in. long, purple*................26. **sagittata**
HH. *The lvs. cordate.*
I. *Corolla small, ½–¾ in. wide.*
J. *Color of corolla yellow*..27. **chryseides**
JJ. *Color of corolla white: fls. in dense cymose clusters*.............28. **sidæfolia**
II. *Corolla large, 2–4 in. long.*
J. *Foliage whitish tomentulose: fls. cream-colored with a magenta throat*..............29. **macrorhiza**
JJ. *Foliage not whitish tomentulose.*
K. *Color of corolla white, 3–4 in. long: caps. large, 1 in. diam., operculate-dehiscent*..............30. **Tuba**
KK. *Color of corolla white with a magenta throat: foliage pubescent or glabrate; lvs. pale beneath*....31. **pandurata**
KKK. *Color of corolla pink, yellowish purple or purple.*
L. *Lvs. softly pubescent, plicate-veined: fls. pink or purplish*............32. **Jalapa**
LL. *Lvs. glabrous, acute, cordate, hastate or variously lobed*....33. **Batatas**

1. **longifòlia,** Benth. (*I. Cárletonii,* Holzin.). Sts. glabrous, erect or ascending from a large tuberous root: lvs. linear-lanceolate to oblong-lanceolate, nearly sessile: fls. large, 2–3 in. long, white. Prairies and plains, Okla. to Texas and Mex. and Ariz. Contr. Nat. Herb. 1:17.

2. **leptophýlla,** Torr. Bush Moonflower. St. 2–5 ft. high, with many slender, recurving branches: lvs. 2–4 in. long, entire: peduncle stout, 1–4-fld., usually

1961. Morning-glory, Ipomœa purpurea (×½) shorter than the lvs.; corolla about 3 in. across, funnelform, rose-pink, deepening to purple in the throat. Aug.–Oct. Dry plains, Neb. and Wyo., south to Texas and N. Mex. Plant World 7:5, 6.—This and the preceding species are adapted for very dry places because of the enormous tuberous rootstocks, which often weigh 100 pounds and extend into the subsoil for 4 ft. They sometimes thrive where no rain has fallen for 1–3 years. The plant is beautiful when in flower.

3. **stáns,** Cav. A beautiful erect, branching shrub with a thickened woody root: sts. and foliage finely pubescent: lvs. nearly sessile, oblong, hastate and deeply toothed at the base: fls. solitary on axillary peduncles, pink or purple, 2–2½ in. long. Mex.—The best of the several species of Mexican bush moonflowers, none of which is hardy.

4. **fistulòsa,** Mart. (*I. texàna,* Coulter). St. 4–10 ft. high, subshrubby, branching, smooth or minutely pubescent: lvs. 4–6 in. long, thickish, entire or nearly so: peduncles 1–2 in. long, mostly shorter than the petioles, few- to many-fld.; corolla about 3 in. long, bell-shaped, pink-purple. July–Sept. Brazil; now escaped from gardens in Mex. and S. U. S.—It is known to the trade chiefly as var. **Goòdellii** (*I. Goòdellii,* Hort.). This variety has lavender-pink fls., with a darker throat, and is apparently more floriferous and desirable than the type. It produces seed sparingly, but is easily rooted from cuttings. In the S. it is hardy if the st. is cut down and the roots mulched: in the N., the roots must be brought indoors. Advertised as the "tree ipomœa."

5. **arboréscens,** Don. An erect, woody, tree-like plant, reaching 15–20 ft. height: twigs and foliage finely velvety-pubescent: lvs. ovate-cordate: sepals oval, obtuse, ¼in. long, pubescent within and without; fls. white, 2 in. long: seeds black with a long coma of white hairs on the dorsal angles. Mex. G.F. 7: 364.—Requires a dry cool air like most of the cacti and makes an interesting companion plant to them in a cactus-house.

6. **Wolcottiàna,** Rose. Tree, 25–30 ft. high, often 1 ft. through, with slender, slightly drooping branches: lvs. ovate to ovate-lanceolate, 3–5 in. long, smooth: fls. numerous, in short racemes or corymbs; corolla about 2½ in. broad, white, broadly bell-shaped. Mex. G.F. 7:365.—Seeds do not germinate readily.

7. **Pes-càpræ,** Roth (*I. marítima,* R. Br.). St. creeping, seldom twining, 20–60 ft.: roots often 12 ft. long and 2 in. thick: lvs. 1–4 in. long, fleshy, roundish, often broader than long, with 2 glands at the base and prominently pinnate-veined: peduncles usually few-fld., equaling the petioles; corolla nearly 2 in. long, bell-shaped, margin scarcely lobed. Aug.–Oct. Trop. coasts of both hemispheres; drifting sands of coast, Ga. to Texas. B.R. 319.

8. **stolonífera,** Poir. (*I. carnòsa,* R. Br. *I. acetosæfòlia,* R. & S. *I. littoràlis,* Boiss. not Blume). Sts. glabrous, creeping and often rooting at the nodes: lvs. variously lobed or oblong-lanceolate, not cordate: fls. cream-colored, 1½ in. long. Circumtropical on sandy shores, S. C. to Fla. Cyrill, Pl. Rar. fasc. 1. pl. 5.

9. **Líndheimeri,** Gray (*I. heterophýlla,* Torr., not Ort.). Plant finely pubescent, hoary when young: lvs. deeply 5-cleft or 5-parted, all of the lobes or the 3 interior ones ovate to ovate-lanceolate, with a much contracted base: peduncle 1–2-fld.; corolla long-funnelform, about 3½ in. long, light blue. Rocky soils, W. Texas to N. Mex. Var. **Lindleyàna,** Hort. (*I. Lindleyàna,* Hort.), has smaller lvs., lighter colored fls., and is a more profuse bloomer. An improvement on the type, but more tender.

10. **purpùrea,** Roth (*Convólvulus màjus,* Hort. *Convólvulus purpùreus,* Linn.). TALL MORNING-GLORY. Fig. 1961. St. trailing or twining for 4–10 ft., branching from the base: peduncles slender, 1–5-fld., often longer than the petioles; corolla 1–2 in. long, light blue, purple, pink and diversely variegated. July–Sept. Trop. Amer. Escaped from gardens to waste places, Canada to Fla., west to Neb. and Texas, widely distributed in most tropical regions. B.M. 113, 1005, 1682. Gn. 21, p. 295; 27, p. 473.—One of the most popular of garden annuals. Some of its varieties resemble the entire-leaved forms of *I. hederacea,* but may be distinguished by their longer and more slender peduncles, umbellate pedicels, and oblong-acute sepals without the long tip usually found on *I. hederacea.* Seeds ripen freely on cult. varieties and may be gathered for future sowings. Among the host of garden forms are: **álba,** white; **atro-cærùlea,** dark blue; **atro-sanguínea,** dark purple; **azùrea,** sky-blue; **carminàta,** light crimson; **Díckensonii** (*Phárbitis híspida* var. *Díckensonii*), azure-blue; **Hùberi** (*I. Hùberi* var. *variegàta,* Hort.). Lvs. marked with silvery white, fls. variously colored and margined with white; **kermesìna** (*I. kermesìna*), scarlet; **rôsea,** blush-rose; **vària,** a trade name for packages containing a mixture of many kinds; **violàcea-striàta,** violet-purple. There are several double forms of *I. purpurea.* Var. **flòre-plèno,** Fig. 1962, has very large lvs.: fls. appearing much later than single varieties, semi- or much-doubled, bluish white streaked with light blue or pink. Intro. 1892. Said to be very floriferous and a good pot-plant. G.F. 5:593 (adapted in Fig. 1962). A.G. 14:246. Var. **violàcea fl.-pl.,** Hort., is entirely distinct from the preceding. Gt. 47, p. 133.

1962. Ipomœa purpurea var. flore-pleno.

11. **hirsùtula,** Jacq. (*Phárbitis diversifòlia,* Lindl. *I. mexicàna,* Gray). Like *I. hederacea,* but young lvs. entire or slightly angulate, becoming deeply 3-lobed and cordate, as in *I. hederacea,* the middle lobe broadest: peduncles as long or longer than petioles; corolla 1 in. wide, violet-purple, sometimes with crimson plaits; sepals merely acute, not attenuate and recurved as in *I. hederacea.* B.R. 1988. B.M. 4289.—The plants in the trade as *I. mexicana* are mostly *I. hederacea, I. digitata* and *Calonyction aculeatum. I. mexicana vera,* Hort., *I. mexicana grandiflora alba,* Hort., and *I. mexicana grandiflora hybrida,* Hort., are *Calonyction aculeatum* or *I. grandiflora.*

12. **mutábilis,** Lindl. (*I. dealbàta,* Hemsl. *I. Leàrii,* Meissn. not Paxt.). Perennial from a woody root: sts. densely and softly pubescent: lvs. orbicular-ovate, entire or 3-lobed, appressed silky-pubescent above, silvery canescent beneath: fls. 2–3 in. long, blue or purple with a white tube or throat. Mex. B.R. 39.—One of the most showy and ornamental species of the Pharbitis group.

13. **hederàcea,** Jacq. (*I. Nìl,* Roth. *I. scàbra,* Forsk. and Hort.). St. twining or climbing, 2–8 ft.: lvs.

2–5 in. long, ovate-cordate, the lobes ovate to ovate-lanceolate, entire, or the lateral lobes repand or denticulate: the middle lobe narrowed at the base: peduncle 1–3-fld., mostly shorter than the petiole; corolla funnelform, the tube usually white, the limb light blue, purple or rose, and in various combinations of these colors; sepals hairy, lanceolate, with long and often recurved tips. July–Oct. Widely naturalized from Trop. Amer. in fields and waste places, Pa. to Fla., west to Neb. and Mex. Perhaps native in the South. B.R. 85 and 276 (as *I. cærulea*). B.M. 188 (as *Convolvulus Nil*). Gn. 27, p. 473.—This species shows great variation in the form of its lvs., both on the same plant and on different plants. In some forms formerly known as *I. Nil*, the lvs. are nearly entire; in others they are very deeply lobed. Next to *I. purpurea*, this is now the most popular morning-glory in cult., and the intro. of the improved Japanese strains will extend its usefulness. Before the appearance of these oriental varieties in occidental gardens, the species had already varied into many distinct horticultural varieties; as var. **limbàta,** (*I. limbàta*, Hort.), with the corolla violet-purple, edged with white. B.M. 5720 (as *Pharbitis Nil*). Gn. 29, p. 32. Var. **marmoràta cœléstina,** large fls., marbled and striped with light blue. Gt. 44, p. 592. Var. **marmoràta ròsea,** fls. marbled with rose. Gt. 44, p. 76. Var. **fòliis marmoràtis,** lvs. marked with yellow, limb of corolla rose-color. Var. **grandiflòra,** large blue fls. Var. **Ferrandiàna,** similar to var. *grandiflora*. Aside from these strains, the following named varieties of Japanese ipomœas are offered: Antigone, lvs. variegated: fls. blue, with pink throat. Aglaia, lvs. variegated: fls. crimson, with white throat. Aseria, fls. dull copper-red. Ceres, like Aglaia, but fls. edged with white. Euphrosyne, lvs. variegated: fls. pure white, with pink throat. Princess, fls. spotted with carmine. Gt. 47, p. 133. A form with foliage dotted with white is shown in I.H. 43, p. 75. The various strains give fls. which are diversely scalloped, ruffled, fringed, double, and show a wonderful range of coloring.

14. **Leàrii,** Paxt. BLUE DAWN-FLOWER. St. a very rapid grower, often 30–40 ft. long, somewhat shrubby at the base: lvs. 3–6 in. long, cordate, acute, mostly entire or slightly 3-lobed, variable: fls. borne in clusters of 12–30, opening in succession; corolla 4–5 in. broad, bell-shaped, deep lilac, sometimes dark purple with five lighter plaits. Very beautiful. Aug.–Oct. Tropics of both hemispheres; widespread. B.M. 3928 (as *Pharbitis Leari*). B.R. 27:56 (as *Pharbitis Leari*).—A magnificent species for the warmhouse, but not usually satisfactory outside, at least in the N. One plant is on record as producing 60,000 fls. at the rate of 300 a day. When grown in the open the fls. are likely to be an unattractive coppery purple. Thoroughly naturalized in S. Calif., and a most useful plant for covering waste places, enbankments, and the like.

15. **microdáctylum,** Griseb. A glabrous, woody, perennial twining vine, several feet in height, the sts. often covered with rough corky projections: root large and woody: lvs. 3–5-lobed or sub-entire, thick: fls. scarlet, sub-salverform, about 1½ in. long, the limb as broad and slightly 5-lobed; stamens slightly exserted. Fla. Keys and Cuba.—This is often mistaken for **I. fuchsioìdes,** Griseb., a rare and little-known Cuban species, not found on the Fla. Keys and probably not in cult. Var. **integrifòlium,** House. Lvs. entire, oblong-ovate, subcordate or obtuse at the base. Commoner than the species. Intermediate lf.-forms are often found on the same plant.

16. **Púrga,** Hayne (*I. Jalápa*, Nutt. & Coxe, not Pursh). Lvs. sagittate-cordate, smooth: peduncles generally 1-fld., longer than the petioles; fls. rose-purple; corolla long-tubular, with a flat limb. Sept., Oct. Trop. Amer. B.R. 33:49 (as *Exogonium Purga*).—The "Jalap" of commerce is an active purgative made by grinding to a powder dried slices of the tuberous roots of this species. It was principally collected near Xalapa, Mex., of which Jalap is a corruption.

17. **angustifòlia,** Jacq. (*I. filicaùlis*, Blume). St. prostrate, trailing or rarely climbing, much-branched: lvs. 1–3 in. long, less than 1 in. wide, glabrous: peduncles exceeding the petioles, bearing 1–2 small, bell-shaped fls., which are yellowish white with a purple eye. Aug., Sept. Widely distributed in Trop. Asia, Afr. and Amer. B.M. 5426. B.R. 317 (as *I. denticulata*).—Sometimes grown in the warmhouse, but there is hardly enough foliage to set off the pretty dark-eyed fls.

1963. Ipomœa digitata. (×¼)

18. **trícolor,** Cav. (*I. rùbro-cærùlea*, Hook. *I. Hoòkeri*, Don and Hort.). St. tinged with purple, branched, 10–20 ft. high: lvs membranaceous, much-veined, short-acuminate: peduncle hollow and wand-like, longer than petioles, 3–4-fld.; fls. 3–4 in. wide, the tube white and limb red before expanding, at length purple or china-blue. Aug.–Oct. Mex. R.H. 1855:441 (as *Pharbitis rubro-cærulea*). B.M. 3297. P.M. 3:99. Gn. 27:72. G.C.III.53: 104.—One of the most beautiful of annual climbers. The fls. are often dashed, blotched and shaded with rose, or are entirely rose. It is likely to run to vine when out-of-doors unless the roots are confined in a box or pot to induce early flowering. It makes an excellent pot-plant for the greenhouse. Var. Heavenly Blue, from Calif., proves to be a blue form of *I. tricolor*, which is especially valuable for cut-fls. Var. **álba,** Hort., has pure white fls.

19. **Hórsfalliæ,** Hook. Fls. many, in a 2-branched cyme; corolla bell-shaped, the limb of 5 broad, rounded lobes, very showy. Cosmopolitan tropics. B.M. 3315. P.M. 3:50. F.S. 16:1647.—Perhaps the most popular ipomœa for winter-flowering in a warmhouse. If well treated it will climb 20–30 ft., and will bear hundreds of fls. each day in early winter. May also be grown out-of-doors, but it will not come into bloom till late fall unless the roots are cramped. Var. **álba,** Hort.,

is *I. ternata;* Lady Slade has pale rose fls.; var. **Bríggsii,** (*I. Bríggsii,* Hort.), or Lady Briggs, is generally considered better than the type for most purposes. It is a freer grower and bloomer, the fls. are a rich magenta-crimson, and it roots from cuttings much more readily than *I. Horsfalliæ.* This variety makes a fine plant in a 10-in. pot. G.M. 37:49. Var. *Thómpsonii,* or *I. Thomsoniàna,* Hort., is *I. ternata.*

20. **ternàta,** Jacq. (*I. Hórsfalliæ* var. *álba,* Hort. *I. Hórsfalliæ* var. *Thomsoniàna,* Hort. *I. Thomsoniàna,* Mast.). St. somewhat woody at base: lvs. usually 3-parted, the segms. elliptic or elliptic-oblong, fleshy, smooth: fls. trumpet-shaped, about 2 in. across. Otherwise like *I. Horsfalliæ,* of which it is often considered a variety. Probably from W. Indies. G.C. II. 20:817. F. 1884, p. 118.—Not considered quite so effective for greenhouse cult. as *I. Horsfalliæ.*

21. **aùrea,** Kellogg (*Operculìna aùrea,* House). A slender twining vine, woody below, with very large, white, tuberous roots: lvs. digitately 5-lobed: fls. 2–4 in. across, funnelform, with a widely expanded limb, golden yellow: the rhombic, entire, sub-repand lfts. often deciduous, as are the branches. Lower Calif.

22. **setòsa,** Ker. Brazilian Morning-Glory. Plant very vigorous, branching, covered with stiff purplish hairs: lvs. 3–10 in. wide, cordate, angular or 3-lobed, the middle lobe abruptly contracted below into a narrow neck: peduncles many-fld., longer than the petioles; fls. 2–4 in. wide, salverform, rose-purple. Aug.–Oct. Brazil. B.R. 335.—An excellent free-growing climber for covering arbors, and especially valuable for making a dense screen because of its very leafy habit. In the latitude of New York seeds sown in the open will give flowering plants in late August. It may also be treated as a warmhouse deciduous twiner. Var. Northern Light is said to be a cross with *Calonyction aculeatum.* Plant unusually vigorous, often growing 40–50 ft.: fls. lavender-pink.

23. **sinuàta,** Ort. (*I. dissécta,* Pursh, not Willd. *I. sinitàta,* Hort.). St. somewhat woody at base, covered with long yellowish hairs: lvs. smooth or nearly so, palmately 7-parted, the divisions lanceolate or narrowly oblong, more or less sinuately cut and toothed: peduncles 1–2-fld., longer than the petioles; fls. 1–2 in. wide, bell-shaped, white with purple center; calyx as long as the corolla-tube. June–Sept. Trop. Amer., and near the coast from Ga. to Texas.—In Texas it expands only 2–3 hours at midday, and is there called the "noon-flower." It may be treated as a coolhouse evergreen, and is worth growing for its delicate foliage alone. In the N. the tubers must be wintered in a cellar.

24. **digitàta,** Linn. (*I. paniculàta,* R. Br. *I. palmàta,* Hort., not Forsk.). Fig. 1963. St. trailing or climbing, 20–40 ft.: lvs. 3–7 in. wide, 5–7-parted, the segms. elliptic, sometimes spatulate, entire: fls. numerous, in a 2-branched cyme; corolla 1½–3 in. wide, broadly bell-shaped, 5-lobed, pinkish purple or pink: seeds with a dense tuft of dirty white wool springing from the apex. July–Sept. Tropics of both hemispheres. R.H. 1853:381. B.R. 62; 333 (as *I. platensis*). B.M. 3685 (as *I. platensis*). Gng. 2:311.—One of the best tuberous-rooted ipomœas for the garden or warmhouse. In the N. it may be used with fine effect if grown in a tub and trained to an adjacent pillar or trellis, the vine being cut off before frost and the tub stored. Farther south the tubers may be planted directly in the open, and will give a profusion of bloom nearly all summer. Var. **insígnis,** Hort. (*I. insígnis,* Ker). Lvs. not palmately divided, nearly entire or lobed, the under surface sometimes purplish. B.M. 1790. B.R. 75.—There are few plants of var. *insignis* in cult.

25. **bonariénsis,** Hook. (*I. ficifòlia,* Lindl. *I. Perringiàna,* Damm. *I. Séllowii,* Penny). St. branching, tinged with purple and covered with short stellate hairs: lvs. deeply cordate, 3–5-lobed, the middle lobe longest: peduncles several-fld., longer than the petioles; fls. 1½–2 in. wide, violet to lilac, the limb spreading into 5 crenate lobes. Aug.–Oct. Trop. Amer. and Afr. B.M. 3665. B.R. 27:13. P.M. 9:25. Gt. 47:1446.—Here belongs *I. Sellowii,* Penny, and probably Hort., not *I. Selloi,* Mart., which is a distinct species.

26. **sagittàta,** Lam. (*I. speciòsa,* Hallier, not Pers.). Sts. twining from a perennial root, slender and glabrous: lvs. strongly sagittate, short-petioled: fls. slender, about 3 in. long, purple. Marshes and fields, N. C. to Mex. and W. Indies.

27. **chrysèides,** Ker. St. slightly woody, much twining, smooth or branches slightly hairy: lvs. 1–2 in. long, ovate-cordate to sub-hastate, acute, entire or toothed, 3-angled, 3-lobed and repand: peduncles 1–7-fld., longer than the petioles; corolla ½–¾in. wide, funnel-shaped. July–Oct. Trop. Asia and Afr. B.R. 270.—It can be grown out-of-doors, but is tardy in blooming. Best treated as a warmhouse evergreen climber. *I. chryseides* is advertised abroad. *I. chrysántha,* Hort., described in American catalogues as having rich, glossy foliage and golden yellow fls., may belong here.

28. **sidæfòlia,** Choisy (*I. corymbòsa,* Don. *I. cymòsa,* Lindl. *I. antillàna,* Millsp. *Turbìna corymbòsa,* Raf.). A slender, climbing perennial vine, woody below: lvs. ovate, cordate, small or medium-sized: fls. borne in large cymose clusters on elongated branching peduncles; corolla white, 1½ in. long and broad; sepals somewhat wing-like in fr.: caps. turbinate, usually 1-seeded. Fla., W. Indies, and Trop. Amer.

29. **macrorhìza,** Michx. (*I. Micháuxii,* Sweet. *I. Jalápa,* Pursh, in Bot. Mag. 1813, not Pursh's description, 1814). Sts. perennial from a thickened woody root, trailing or climbing 6–8 ft. high, springing from an oblong root weighing 4–30 pounds: foliage whitish with a soft tomentulose pubescence; lvs. entire, repand, or lobed, 3–5 in. long, ovate-cordate, membranaceous, veiny: peduncles 1–5-fld.; sepals very unequal, the inner ones ½in. long and twice as long as the outer ones; fls. about 3 in. long, cream-colored, with a magenta throat. S. C. to Fla. and Mex. B.R. 342.—A very ornamental warmhouse climber and valuable for the garden if the tubers are started in the greenhouse before being set out; otherwise the plant seldom blooms much before frost. The "Jalap" of commerce does not come from this plant, but from *I. Purga.* The roots of *I. macrorhiza* are but slightly purgative.

30. **Tùba,** Schlecht. (*I. latifòlia,* R. & S. *I. ventricòsa,* Don. *I. grandiflòra,* Lam. *Calonýction grandiflòrum,* Choisy). A stout, twining, perennial, woody vine. foliage glabrous or nearly so; lvs. ovate, cordate, 5–10 in. broad, thickish in texture: fls. white, funnelform, about 4 in. long: caps. large, 1 in. diam. with an operculate dehiscence. Amer. Trop.—Some of the inferior strains passing as *I. Bona-nox* and its synonyms belong here. Not a proliferous flowerer, and in cult. rarely successful.

31. **panduràta,** G. F. W. Mey. Man-of-the-Earth. Wild Potato-vine. St. 2–12 ft. long: root very long and large (10–20 pounds): lvs. 2–4 in. long, long-petioled, usually cordate and entire, occasionally angulate, fiddle-shape or hastately 3-lobed: peduncles 1–5-fld., commonly a little longer than the petioles; corolla 2–4 in. wide, broadly funnelform with pointed lobes, white with a dark purple throat. May–Sept. Dry soils, Canada to Fla., west to Ont. and Texas. A.G. 12:637. R.H. 1893:574. B.M. 1603 (as *Convolvulus candicans*), 1939, and Gn. 27, p. 373 (both as *C. panduratus*). B.R. 588.—In some places this species is a very troublesome weed, which is almost impossible to exterminate because of its long tuberous roots.

It can easily be kept within bounds in the garden with a little care, and makes a very desirable plant for covering an old dead stump or back fence. The chief merit of *I. pandurata* as a garden plant is its hardiness; hence it is often sold as the "hardy" or "perennial moonflower." If well mulched the roots will stand 26° below zero. There is a double-fld. form. It is sometimes escaped in cult. grounds.

32. **Jalápa,** Lindl. (*Batàtas Jalápa,* Choisy). A slender, glabrous, twining vine from a large woody root: lvs. triangular-ovate, entire or 3-lobed, plicate-veined: peduncles usually very short, 1-fld.; sepals sub-equal, broadly ovate, obtuse, ¼in. long; fls. slender funnelform, 2–2½ in. long, pink or purple. A Mexican species, the roots of which possess purgative powers equal to those of *I. Purga.* L.B.C. 6:518.—The names of this and *I. macrorhiza* have been confused from the fact that this plant, figured by Lindley in 1813 (B.M. 1572) as *Convolvulus Jalapa* (*I. Jalapa,* Pursh, as synonym) is not the Carolinian plant described by Pursh under that name in 1814. The plant described by Pursh as *I. Jalapa* is the *I. macrorhiza* of Michaux.

33. **Batàtas,** Poir. (*Batàtas édulis,* Choisy). SWEET POTATO. Lvs. ovate-cordate, usually angular or lobed, variable, petioled: peduncles equaling or exceeding the petioles, several-fld.; corolla 1–2 in. wide. Origin probably from *I. fastigiata* of Trop. Amer. (*I. platanifolia,* R. & S.).—Largely cult. in many varieties for its edible tubers. See *Sweet Potato.*

Several species of slight ornamental value occur in the southern states, and are sometimes seen in cult. *I. desertòrum,* House. Resembling I. hederacea but rough-pubescent and adapted to drier situations. Ariz.—*I. lacunòsa,* Linn. Annual with small white fls., often with a pink limb. Pa. to S. C., Ill. and Texas.—*I. polyánthes,* R. & S. (I. umbellata, Mey.). Small yellow fls. in umbels. Fla. and Trop. Amer.—*I. trichocárpa,* Ell. S. C. to Fla., Kans. and Mex.—*I. tríloba,* Linn. Pink or purple corolla ⅔in. long.: lvs. 3-lobed. Fla., Ariz. and Trop. Amer.

The two following species of recent intro. are as yet not common in the trade: *I. Macalùsoi,* Mattei. Slightly pubescent, woody sts.: lvs. ovate-orbicular, abruptly acute and mucronate, deeply cordate; petioles long, somewhat villous: fls. axillary, in subsessile cymes; corolla large, campanulate, orange-colored, margined with red. Native of Italian Somaliland.—*I. Mahònii,* C. H. Wright. An erect shrub with oblong lvs. about 1¾ in. long and 1 in. broad, obtuse at both ends, entire: petioles ¾in. long: corolla-tube deep reddish purple, paler above, the limb white or slightly suffused with pink, over 3 in. broad. Native of Uganda.

See Quamoclit for *Ipomœa Quamoclit, I. coccinea, I. vitifolia,* and *I. hederæfolia.* See Calonyction for *I. Bona-nox* and *I. tastense.* *Ipomœa Howardii,* P. D. Barnhart, Pacific Garden 4: No. 9, p. 5, Aug. 1911=Quamoclit grandiflora.

H. D. HOUSE.†

IPOMÓPSIS: *Gilia.*

ÍPSEA (fancied resemblance to *ips,* a cynip insect or a worm). *Orchidàceæ.* Two or 3 terrestrial E. Indian pseudobulbous orchids, allied to Pachystoma, with which it has been united: lvs. long, narrow and plicate: scape sheathed; fls. few, large, highly colored. **I. speciòsa,** Lindl. (*Pachýstoma speciòsum,* Reichb.). Deciduous, tuberous-rooted, with erect scapes to 18 in. high: lvs. 5–8, long-petioled, 6–10 in. long: fls. several, bright yellow, fragrant, 2–3 in. diam., the lip oblong, with side lobes triangular and middle lobe obovate: pseudobulbs tufted. Ceylon. B.M. 5701. G. 26:189.—Blooms in winter. To be potted in fibrous loam, peat and leaf-mold, and rested after growth.

L. H. B.

IRESÌNE (Greek name for a harvest garland wound with wool: the flowers and seeds of these plants are woolly). *Amarantàceæ.* ACHYRANTHES. Ornamental-leaved bedding plants.

Low, spreading, climbing or erect herbs or subshrubs: lvs. stalked, opposite, the margins not toothed in the domestic species: fls. very small, bracteate, in axillary or terminal panicles, perfect or imperfect (plants sometimes diœcious), the perianth of one series terete, 5-parted, with ovate-oblong segms.; stamens 5; style short or none, the stigmas 2 or 3: fr. a utriculus.—Species 20–25 in Trop. and Subtrop. Amer. Two or 3 species are in common cult. as bedding-plants, because of their highly colored lvs. and sts. The first of these to be intro. was described before the fls. were known and it was referred to Achyranthes (*A. Verschaffeltii*), but in that genus the anthers are 2-loculed, whereas in Iresine they are 1-loculed. To gardeners they are still known as Achyranthes.

Because of ease of propagation, ability to withstand sun and shearing, and the bright colors, the iresines are amongst the most popular bedding-plants. Few plants are easier to grow. Stock plants are kept over winter in a cool temperature (as in a carnation house), and in February and March they are given more heat and moisture, and cut back, to get cutting wood. Cuttings root quickly in any good cutting-bed. For mass bedding, plants are usually set 6 to 10 inches apart. They will not withstand frost.

1964. Iresine Lindenii. (×⅛)

Hérbstii, Hook. f. (*Achyránthes Verschafféltii,* Lem.). Lvs. broadly ovate or orbicular, obtuse and notched at the apex, purple-red, with prominent arched veins, or in the commoner variety green or green-red with yellow veins (var. *aùreo-reticulàta*). S. Amer. B.M. 5499. H.F. II. 7:103. This was described and figured in Aug., 1864, by Lemaire as *Achyranthes* (?) *Verschaffeltii* (I. H. 11:409), and later by Van Houtte as *Iresine Verschaffeltii* (F. S. 15:1601). In July, 1864, however, Hooker had published it as *Iresine Herbstii,* in honor of Mr. Herbst, of the Kew Nursery, who intro. it from the River Platte. There are horticultural varieties with Latin names. *I. Wállisii,* Ort., is a small form, with numerous small roundish lvs., which are bronze-red or dark red above and dark blood-red beneath. *I. brilliantíssima,* has rich crimson color.

Líndenii, Van Houtte (*Achyránthes acuminàta,* and *I. acuminàta,* Hort.). Fig. 1964. Lvs. ovate-acuminate or lance-ovate, with less arching or curving veins, in the original form rich, deep blood-red, but in some garden forms with light-banded veins. Ecuador. F.S. 17:1737. G.Z. 13:32.—More pyramidal in habit than the other species, and now more common. To this species evidently belong the garden forms known as *I. Emersonii, I. Collensii* and *I. formosa.*

I. Biemuèlleri, Voss (Achyranthes Biemuelleri, Haage & Schmidt), is probably a garden form of one of the above. It is a compact, dwarf grower, withstanding severe cutting: lvs. and twigs rose-carmine.

L. H. B.

IRIÁRTEA (after Bernard Iriarte). *Palmàceæ.* Tall spineless palms, with cylindrical or swollen stems supported on a pyramid of exposed roots.

Leaves few, unequally pinnate; lfts. equilateral, cuneate, entire or erose, plicate; petiole channelled; sheath cylindrical: fls. small: fr. 1–2 in. long: stigmas eccentric or lateral in fr. This palm is separated from Ceroxylon by the cuneate lfts.—Species 10. Trop. S. Amer. *I. Bungerothii* was advertised in 1895 as Triartea, which was presumably a typographical error for Iriartea. This is a horticultural name for *I. exorrhiza,* Mart., but the plant is in cultivation under the former name.

exorrhìza, Mart. (*I. Bungeròthii,* Hort.). Trunk about 35 ft. tall, crowned by a congested cluster of 10–20 showy lvs., each bearing 15–20 pairs of lfts., the latter about 20 in. long and 1½ wide: spadices 1–4, appearing between the lvs.; fls. yellow: fr. olive-green, reticulate. Trop. S. Amer.—Doubtfully in cult. at this time (1913) in Amer.

N. TAYLOR.†

ÌRIS (Greek, *rainbow*). *Iridàceæ.* Plates LVIII, LIX. Showy and interesting flowers for outdoor bloom, widely known and planted; perennials with rhizomes or bulb-like root-stocks, mostly narrow long leaves, and commonly erect habit; includes the blue flag and fleur-de-lis.

Herbs with linear or ensiform equitant lvs.: st. simple or branched: fls. of 6 segms., the 3 outer reflexed, and the 3 inner usually smaller and erect, always narrowed to a distinct claw, 1 to many in terminal heads, from spathes which are formed of the upper bract-like lvs.; spathe stalked or sessile; style divided into 3 petal-like branches, which are bifid or crested at the tip; stigmatic surface immediately below the crests; ovary sessile or pedicelled, within the spathe.—Distinguished from the other members of the tribe except Hermodactylus and Moræa by the 2-winged style-branches, from Hermodactylus by the 3-celled caps., and from Moræa by the more or less connate perianth-segms. For monographs of the genus, see Baker's Irideæ, 1888, Lynch, The Book of the Iris, 1904, and the fine monograph of Dykes, The Genus Iris, 1913. The number of species of Iris recognized by different monographers ranges between 140 and 170. The synonomy includes something over 700 names. The extensive synonomy is an indication of the great variability and wide distribution of the genus. In general the irises are natives of the North Temperate Zone, but the different subgenera differ much in their distribution. The distribution of some of the subgenera is coextensive with that of the genus, while others are restricted to limited regions. The subgenus Apogon is the largest and also the most widely distributed section of the genus. Its representatives are found throughout temperate N. Amer., Eu., Asia and N. Afr. They extend from Alaska, Labrador and Kamtchatka in the north to Fla., Algiers and Honkong in the south. The members of the subgenus Pogoniris, which is the second largest and horticulturally the most important section, are found in Cent. and S. Eu. and N. Afr. and thence eastward to China and N. W. India. No members of this subgenus are indigenous to Amer. The small subgenus Evansia comprises a few species of crested irises which, with the exception of the two closely related American forms, *I. cristata* and *I. lacustris,* occur only in Japan and E. China. The American species differ widely from the far eastern ones in the absence of an evident stem. The subgenus Oncocyclus is a small section whose members are restricted to a limited region in Asia Minor, Syria, and Persia. Farther to the east, in Turkestan, the Oncocyclus irises are replaced by the members of the closely related subgenus, Regelia. In N. India in the region to the south of the Karakoram and Himalayan Mts. are found a few species constituting the subgenus Pseudoregelia, so named on account of the affinity of its members to those of the subgenus Regelia. The peculiar oriental subgenus Pardanthopsis contains only a single species, *I. dichotoma,* which is found in Manchuria and N. China. The bulbous irises comprise three subgenera, Xiphium, Juno, and Gynandriris. The subgenus Xiphium is sometimes divided into two sections, the Xiphiums proper, which occur in Spain, Portugal, Sicily and N. Afr.; and the reticulata irises, which are found in Asia Minor, Transcaucasia and Turkestan. The Juno irises occur in Spain, N. Afr., Asia Minor, Persia, and eastward to India. The single species of the monotypic subgenus Gynandriris is distributed from Portugal to N. W. India.

Something over 100 species of Iris, with innumerable garden varieties, are offered by dealers in America. Many of these, including the native species, are cultivated only to a slight extent, so that horticultural interest centers chiefly around the groups described below.

1. *German irises.*—Under this head may be grouped the tall European pogonirises and the numerous varieties and hybrids derived from them. Besides *I. germanica,* which may be taken as the type of this class, the principal species of the group are *I. aphylla, I. variegata, I. florentina, I. pallida, I. Cengialti, I. flavescens, I. plicata, I. Swertii, I. Kochii, I. lurida, I. neglecta, I. sambucina, I. squalens* and *I. hybrida.* Many of these which are usually recognized as species are undoubtedly of garden origin. *I. germanica* itself is not certainly known to occur in a native state. *I. florentina* or *I. albicans* is a common ornament in Mohammedan cemeteries and was undoubtedly distributed throughout the Mediterranean region by the Mohammedans, who carried it everywhere with them as an embellishment for graveyards. *I. Kochii, I. lurida, I. neglecta, I. sambucina* and *I. squalens* are probably hybrids of which there are innumerable forms in this group. *I. Swertii* and *I. plicata* are pale forms of *I. Cengialtii* and *I. pallida,* in which the color is absent except along the margin of the segments. *I. hybrida* probably represents a similar derivative of *I. variegata* in which the yellow color is absent. Owing to their diversity of origin, the varieties of this group have a great diversity of color, ranging from pure white through all shades of mauve and blue to dark purple. From *I. variegata* and *I. flavescens* the yellow-flowered varieties and those whose flowers are variegated with yellow were probably derived. The flowers of all the varieties are large and handsome, often stately, exhibiting beautiful variegation and shades of color. They are borne on stout, erect, branched stalks much exceeding the clumps of spreading leaves. All are hardy, and form excellent border plants, flowering in May and June.

2. *Japanese irises.*—All the plants cultivated as Japanese irises are referable to a single species, *Iris lævigata,* more commonly known as *I. Kaempferi.* The type of the species has been so much broken that its varieties constitute a distinct horticultural group, containing perhaps as many or more named varieties than the germanica group itself. So far as known, no hybrids or other species enter into the make-up of this class. The plants form strong clumps, attaining a height of 2 to 3 feet, and bearing several flower-stems. The leaves are slender, erect, growing almost parallel to each other. In the wild type the inner segments are erect and rather small. The cultivated forms fall into two groups,—the three-petaled forms in which the inner segments have been nearly suppressed while the outer segments constitute the showy part of the flower, and the six-petaled forms in which all the segments are large and spreading giving the flower the flat expanded form characteristic of the group. The flowers range in color from white through various shades of blue to deep purple, with the segments variegated with darker veins and streaks, or plain. All the varieties are hardy, and thrive best in cool, moist situations. They begin flowering in the latter part of June and continue through July.

3. *The tall apogon irises.*—Besides the Japanese irises, two other groups of apogon irises deserve mention on account of their ornamental value. These are the sibirica group and the spuria group. The species of the sibirica group which are of horticultural interest are *I. sibirica, I. sanguinea, I. Wilsonii,* and *I. Delavayi.* The plants of this group are characterized by long grass-like leaves growing in close tufts from which

arise clusters of tall branched flower-stems 2 to 3 feet in height. *I. sibirica* has several varieties ranging in color from deep blue to white. These, with the addition of *I. Wilsonii*, make it possible to have tall clumps of blue, white, and yellow irises of the sibirica type. *I. sanguinea*, which has the flowers partly hidden among the leaves is less ornamental than *I. sibirica*, in which the flowers are raised high above the leaves. *I. Delavayi* is a blue-flowered species which flowers in July when most other irises have passed. The plants of this group all thrive best in rather moist situations. Of the spuria group, only the tall ornamental forms closely allied to *I. spuria* are considered here. The most commonly cultivated forms are *I. spuria*, *I. halophila*, better known as *I. Gueldenstædtiana*, *I. orientalis*, *I. Monnieri* and *I. aurea*. These differ from each other only in minor characteristics such as color and slight modifications in the shape of the segments. They are frequently all regarded as varieties of a single type, *I. spuria*, but for horticultural purposes it is more serviceable to treat them as separate species. Besides those forms which may be said to approach specific rank, innumerable minor varieties exist in the group. The color of the flowers ranges from blue in *I. spuria* to bright yellow in *I. Monnieri* and deep yellow in *I. aurea*. In *I. orientalis* the flowers are pale yellow bordered with white. The proportion of white and yellow varies much in different specimens. The plants of this group are tall and stately with leaves 1 to 2 feet long, drooping gracefully above. The flower-stems usually rise high above the leaves, and bear two to three heads of flowers. Those on the lateral branches are held close to the main stem so that the whole inflorescence has the appearance of a spike. The stems are usually 2 to 3 feet high. Those of *I. aurea* are said to grow to a height of 5 feet in California. Some of the species are natives of swampy regions and consequently thrive well in wet places. All grow well, however, in almost any situation.

4. *Dwarf irises.*—Dwarf irises occur in several subgenera but the best-known and most commonly cultivated forms are the dwarf European pogonirises, including *I. pumila*, *I. pseudo-pumila*, *I. biflora*, and *I. Chamæiris*. These are remarkable for their numerous color varieties, which range from pale yellow to lilac, blue, purple, and very dark red. Most of the forms in cultivation are varieties of *I. pumila* and *I. chamæiris*, but many of the garden forms which pass as varieties of *I. pumila* are derived from *I. Chamæiris*. *I. pumila* and *I. Chamæiris* are the most satisfactory of the group, as the others are less hardy or less floriferous. *I. arenaria*, the Hungarian form of *I. flavissima*, thrives well in dry sandy situations. The most common dwarf forms among the apogon irises are *I. humilis*, *I. ruthenica* and the American *I. verna*. Of these, *I. verna* is the most striking because in all characteristics of habit and growth it resembles a pogoniris but lacks the beard characteristic of that group. *I. cristata* and its close relative, or perhaps subspecies, *I. lacustris*, are dwarf American forms belonging to the subgenus Evansia, or crested irises. The dwarf irises seldom grow over 9 inches high. They spread rapidly by their creeping rhizomes and soon form large patches. This habit makes them useful as border plants.

5. *Oncocyclus irises.*—The oncocyclus irises differ from other irises in several striking characteristics. The seeds have a creamy-white aril nearly as large as the seed itself. The stem is surmounted by a long, unkeeled tubular spathe which reaches beyond the top of the perianth-tube. The stem bears a single flower, which in some species is of enormous size, compared with the size of the plant. The segments, of which the inner are larger than the outer, present a most singular combination of somber colors. The peculiar colors are often due to the interlacing of numerous very thin veins, usually blue or brown, on a white or straw-colored ground. The most common shades thus produced are beautiful sky-blue, light gray, and brown to almost black. In some, all the segments are colored nearly alike, but in most species the inner and outer segments are differently colored. The species fall into two groups according to their geographical distribution. With their distribution other characteristics are curiously correlated. The species occurring in central and eastern Asia Minor, Transcaucasia, and the mountains of northern and western Persia are dwarf slender species differing from each other by well-marked characteristics. Those found in Palestine, Syria and Mesopotamia are tall, attaining a foot or more in height, and resemble each other so closely that they cannot be distinguished by any characteristic except the color of the flowers. These apparently are all varieties of a single species. In America the oncocyclus irises are not widely cultivated. The most commonly grown form is *I. susiana*. Many hybrids have been raised in Europe. For a monograph, see Foster, Gn. 43, pp. 130–135.

6. *Bulbous irises.*—About 20 species of bulbous irises are cultivated in America. They are rather dwarf, hardy and half-hardy bulbous plants, known chiefly for the brilliant colors and strong contrasts, and for their numerous flowers. The species most commonly found in gardens are *I. Xiphium*, better known as *I. hispanica*, and *I. xiphoides* or *I. anglica*. The latter is probably the oldest iris in cultivation. See Foster, G. C. II. 23, pp. 567 and 726, and Foster, Bulbous Irises (1892).

HEINRICH HASSELBRING.

The cultivation of irises.

As will be seen by their distribution, irises are especially adapted by their hardiness to growth in our gardens, though some forms, as the African, the Indian, and the Oncocyclus species, need special treatment or protection. In the main, the irises, from a cultural point of view, are like others of the various natural families, mostly very good—not to say commonplace—with a few decidedly inferior members. As there are nearly 170 species of irises, with countless varieties, they are interesting to the amateur collector and grower both for their variety and their general beauty of flower.

The life of iris flowers varies from three to six days. They are fragile, but if cut before the petals unroll may be forwarded to considerable distance without injury. This is the only way, in fact, by which the florist can market them. The botanists divide the irises into two main groups, the bulbous kinds and those with rhizomes, these groups being each divided by the varying characters of the more or less raised line in the middle of the fall of the flower. This, of course, gives no clue to cultural necessities or to time of flowering, two important details in a garden.

Considering the bulbous irises as a group, these are all hardy without protection in the latitude of New York city except *I. Histrio*, *I. alata*, *I. juncea*, *I. palæstina*, *I. tingitana*, *I. Vartanii*.

In the order of their flowering, the reticulata group is the earliest, *I. Bakeriana* and others starting into flower as soon as released by frost, usually in February or March. These are soon followed by the others of this group, the largest-flowered member being *I. histrioides*. A peaty, sandy soil seems to be most acceptable to this group, and no organic manure must be given them. A location, if possible, where they may be kept on the side of dryness in summer is desirable. The culture of these, like that of all exotic plants in our gardens, is, of course, tentative. If, on trial, they seem to be happy and increase from offsets or buds, they may remain in the borders indefinitely, but if during the second season they show no gain, the bulbs should be lifted and a trial made in another location. This group seeds freely, and the seed-pods will be found just under the soil surface.

Closely following this group are the so-called Juno irises, of which *I. persica* is the most familiar, though not the best example. These irises have somewhat large bulbs, with curious persistent, fleshy roots, and seem to thrive best in somewhat stiff soil, in sheltered locations, where they will be well baked during the summer. They flower in March and April, the best forms being *I. Rosenbachiana*, *I. orchioides*, *I. sindjarensis*, and *I. assyriaca*. They are desirable plants in the most exclusive gardens. They seed freely, and also increase by offsets.

About the same time as above will flower the *Iris tuberosa* ("The Widow"), which is neither bulbous nor an iris strictly, but has a weird beauty of its own, with its green and black flowers. This should have a summer baking. See *Hermodactylus*.

Planted out in the early fall, the so-called Spanish irises make an early start and produce leaves which are persistent during the winter and seldom injured here. In May and June they broaden out, and are then surmounted by very bright, distinct and charming flowers. Very satisfactory flowers, these, and of the easiest culture. They probably do best in spots inclining to moisture. The bulbs make offsets rapidly, and should often be divided and replanted. There are two forms and numerous flowers of this iris. The boldest form is that known as the "Thunderbolt." Spanish irises, under mild forcing are now largely grown by florists for early spring flowers.

The "English" irises, *I. xiphioides*, follow the "Spanish" in June and July. Their flowers are wider in all their parts, and in a limited range of colors, white and purple. "Mt. Blanc," pure white, is probably the most satisfactory of the group. The foliage of the English iris does not bear till early spring, and the varieties flourish in a rather drier position than the "Spanish."

The African bulbous irises, *I. juncea*, *I. Vartanii*, *I. alata*, are subjects for a coolhouse, though the former is rarely hardy here.

The rhizomatous irises may be divided into a number of sections, but in a cultural way may be broadly considered in two sections: those with thick, surface-creeping rhizomes, as the hybrid German, and those with more or less thin ones, as *I. sibirica* and *I. lævigata*, which are subterranean. While the former section comprises plants which grow in various conditions, some with the roots submerged, yet in a general way they have mostly surface-creeping rhizomes. These are best transplanted soon after flowering, at which time they commence a new growth. It is customary for the nurserymen to supply these in the fall, which usually leads to the loss of a season, as they often fail to become established when planted late. The foliage of the iris indicates a sun-loving family, and irises should be planted in full exposure in rich, but not manured soil, well drained. The rhizomes should be planted flat and covered to half their diameter. If the rhizomes are in a growing condition, no further care will usually be necessary with the larger number of the species, but if the rhizomes are dormant and partly dried up, as they are frequently on receipt, care should be taken that they have not much moisture till they start into growth, otherwise they are likely to rot. Not every iris will grow in every garden, but the failure to establish these plants is most often caused by too much exposure to excitement of light, warmth and moisture when the plant is not ready to convert its reserve into food. Valuable species should have the protection of a frame in such circumstances till it seems safe to plant them out. If carefully treated and not excited, apparently hopeless dried-up rhizomes may often be saved. Most of these irises in common cultivation increase rapidly, and should be divided and replanted every two or three years; otherwise the rhizomes become matted and the abode of grass. Among them will be found some of the showiest flowers of the family.

Usually in early May *I. Chamæiris* and its variety *I. olbiensis* flower, followed quickly by the dwarfer *I. pumila* and its white form *I. attica*. Forms of *I. lutescens*, Lam., quickly follow, after which *I. germanica*, *I. florentina* and the host of "hybrid German" varieties come rapidly forward and give a great wealth of color. Everyone is familiar with the great bearded purple *I. germanica*, perhaps the most generally cultivated iris. There are larger-flowered forms of this: *I. amas* and *I. macrantha*. *I. germanica alba* seems to be a variety of *I. albicans*. This and *I. florentina* are the usual white-flowered forms seen at this time. Of bold, lighter purple kinds, *I. pallida* and its hybrids are then preëminent.

The German irises of the garden are not varieties of *I. germanica*, but hybrids of various species, as *I. pallida*, *I. variegata*, *I. sambucina*, *I. squalens*, *I. lurida* × wild forms and *I. neglecta*, *I. amœna*, *I. plicata* and *I. Swertii*, which are known only in gardens. Naturally these vary much in stature, time of flowering, size and coloring of flowers. They may be had in almost endless variety, but a typical collection may be made with comparatively few plants.

Among the best forms of the "hybrid German" irises are: *I. aphylla*—Bridesmaid, Madame Chereau, Swertii; *I. amœna*—Compte de St. Clair, Fairy Queen, *reticulata alba*, Victorine; *I. neglecta*—Cordelia, Wagner; *I. pallida*—Khedive, Mad. Pacquitte, Queen of May, Walmer; *I. squalens*—Arnols, Jacquiniana, Harrison Weir, Mons. Chereau; *I. variegata*—Beaconsfield, Darius, Hector, Honorable, Prince of Orange.

June is flowering time for many iris species, many of which are uncommon, but of the more available forms one could scarcely neglect the native *I. hexagona*, the dark La Mance form of which is very distinct and amongst the handsomest of the family. A white form of this is not hardy here. *I. fulva*, another native plant with copper-colored flowers, is also interesting. Irises with distinct forms are *I. Monnieri* and *I. orientalis* (or *I. ochroleuca*), both of which have obliquely growing rhizomes and enjoy moisture.

For margins of water *I. Pseudacorus*, with yellow flowers, is invaluable, and our natives, *I. versicolor* and *I. caroliniana* seem as happy in the moisture as in the uplands. The iris rhizomes which require deep planting are mostly smaller and thinner than those of surface creepers. The species with these roots are mostly strong-growing plants, rapidly increasing and requiring an abundance of moisture, though there are some notable exceptions to be mentioned later. Of the members of this group, *I. sibirica*, in several purple and white forms, is a common garden plant. *I. ensata* is a common Asiatic iris with small flowers borne among the narrow foliage, which is as ornamental as some of the large grasses.

The Japanese irises, which usually end the general display of irises, are a remarkable example of type-breaking, the occidental gardeners having worked up from *I. lævigata* a wonderful variety of colorings and variation in number of petals, though the colors may be included in about half a dozen general types. There are few handsomer flowers than good forms of the white Japanese iris. This iris may be grown on the upland, but it does not do its best in such locations, for it is particularly susceptible to good treatment, and to produce large flowers both water and manure are essential. Peter Barr, the veteran fancier of good plants, wrote from Japan, after consulting one of the oldest cultivators, that "this iris is grown in the rice-fields in winter and watered each month while at rest with human manure (cow manure would do); as soon as young growth appears no more manure is given and the ground is flooded. When growth has ended the water is withdrawn."

One of the most curious things in connection with the Japanese iris is that though these plants have been in cultivation here since soon after the treaty ports were first opened, they seem to have excited little attention from gardeners until within a few years. Yet the first importations were as handsome as the later. In this connection it may be said that Japan has also *I. gracilipes*, a dark purple hardy form, and *I. japonica* or *I. chinensis*, one of the beauties of the family but, like *I. tectorum* (the roof iris), another crested kind, needing here greenhouse protection and well worth it. There is, however, a perfectly hardy crested iris, the beautiful dwarf *I. cristata* of the upper southern states—a charming plant for a front border or rockery. Equally dwarf are our lake irises *I. lacustris* and *I. verna*.

The west coast of the United States is fortunate in possessing some beautiful and distinct irises, mostly of the wiry-rooted, thin-leaved type. They have not yet been fully separated botanically, and they are most difficult things to establish in eastern or other gardens, so that there are really very few in cultivation.

I. macrosiphon, *I. Hartwegii*, *I. Douglasiana*, *I. bracteata*, *I. tenax*, *I. longipetala*, *I. tenuis* and *I. Purdyi* is a list which will interest the searcher after interesting plants. Max Leichtlin, who has a genius for growing difficult things, has been successful in establishing *I. bracteata*, *I. macrosiphon* and *I. Purdyi*. He says, "My experience is that they cannot be moved unless in full vegetation. We must grow them from seed, and not touch the seedlings until they have formed a solid rootstock. After this and movement to grow has begun, they can be safely handled and transplanted like other irises."

Seed should be sown in the open in autumn, plants appearing in the spring should be undisturbed, and in the fall covered with a frost-proof frame. They should flower the second (or third) season. After flowering they may be shifted carefully, but must always have protection as they naturally commence to grow very early and frosts are fatal to them. Only in this way is there much chance of success with these rare plants. Some of the species have been flowered here under harsh conditions but they were survivals of large numbers of collected plants.

There remain to be considered two allied groups, the oncocyclus and regelia. These are considered by amateurs the most interesting groups of the iris family—interesting in the amateur's vocabulary meaning something rare and difficult. At the best, these plants give few flowers, but they compensate for this by their distinct and quaint beauty. The best-known member of the family, *I. susiana*, has been in cultivation several hundred years, but is by no means yet a common plant. It takes more kindly to cultivation than any other of the groups, will usually flower in the border the first year after planting if the spring is not too rigorous; and gardens are not unknown where, from some conditions of fortunate placing or soil, they continue to flourish. It cannot be said that there is any hard and fast formula for growing these irises. They vary among themselves as to their requirements, and need special and different treatment in different gardens and climates. These irises are natives of Palestine, Asia Minor, the Caucasus, central Asia and Persia regions, all of which are hot and dry in summer, with a settled and sometimes severely cold winter and a genial spring. In some of the regions they are protected by a covering of snow in winter while dormant, but Palestine and Persia have open winters, and their irises make growth at this time. After cultivating most of the species for a number of seasons, the writer's experience does not lead him to dogmatize much on their cultivation or to approve of many special devices which have been put forward from time to time as the solution of the problem. The consensus of opinion among the growers who have had the best success with these plants is about as follows, premising that one is dealing with plants which are perfectly hardy: The rhizomes are received with the Dutch bulbs in the fall, at which time they are dormant and leafless. It is well to store them in a cool place and plant out in November in a bed of fairly light and well-drained soil in a border fully exposed. They require no protection, but if the climate is one where frosts and thaw alternate, it is well to give the ground a covering while frozen to keep it firm. The irises so planted will seldom spear here till genial weather arrives, and with plentiful supplies of moisture at the root will give flowers from strong buds. After flowering, or, more accurately, flowering time, one is forced to choose between two methods of treatment. If the garden is high, dry and hot, the best procedure is to cover the beds with a glass frame sufficiently large to protect them from moisture and allow the rhizomes to bake. This frame may be removed in the late fall. If the leaves appear, as some of them are likely to do, they may be left unprotected until very severe weather sets in, that is, usually in December. Coal-ashes have also proved satisfactory, though unsightly. Foliage does not seem to become as soft under them as under leaves or mats. If the spring is genial, with weather steadily becoming warm, the plants, being uncovered as soon as the conditions will seem to warrant, should be in the best possible shape to reward one with their noble blooms. It is the lack of this genial spring in the latitude of New York which, however, leads often to cultural troubles. The leaves, having been protected, are none too hard, and, with the constant alternate thawing and freezing, and the high winds, hot and cold, the plants need constant watching and application of needed covering till really genial weather. Otherwise the foliage is blighted and no flowers are produced. The most satisfactory way, if one is more interested in results than in garden problems, is to grow oncocyclus and regelia iris and the numerous hybrids which are now available continuously in a coldframe. The frame should be located where drainage is perfect with no bottom moisture, so that the plants may be kept perfectly dry and baking after the blooming season. The plants should be protected from hard freezing after leaves are formed, but should not be protected enough to make them soft. The trouble of this procedure is well worth while if one wishes a rare display.

In gardens which are low and never free from moisture, the best procedure is that followed in Holland, lifting the rhizomes in July and taking them under cover in dry earth, planting out again in the fall. In this case care should be used in lifting not to injure the numerous fleshy roots. The Palestine and Persian forms of these irises are considered the most difficult to cultivate, from their habit of early growth.

Irises are not only increased by the division of the rhizomes or by offsets, but may be rapidly grown from seed, which they usually produce freely, though, in most cases, they require artificial fertilization. A large number of the common irises of gardens are hybrids, and of late years a number of beautiful hybrids have been produced between some of the rarer oncocyclus species, and between these also and common forms, as *I. variegata*, and so on. There are still opportunities to produce many new and untried crosses, and experiments in this line are recommended. The pollination of the iris is simple. The anthers should be removed when the flower first opens, and preserved in paper or vials, properly marked. The pollen will retain its potency for a week or perhaps longer, and may be applied to the stigma of the flower selected (the anther of which has been removed promptly) with a camel's-hair brush. The stigma will be found near the apex of the petal-like style, and is ready for pollination when the upper edge drops down and exposes the upper surface. Many iris seeds germinate with considerable irregularity, and failure to start promptly should not lead to discouragement or discarding of the pan in which the seeds are sown.

J. N. Gerard.

The iris in California.

Because such a large proportion of the iris come from around the Mediterranean and so are accustomed to a thorough baking and drying out in summer, their culture is especially satisfactory in California and the range of varieties available so large that some may be found in flower in all but the late summer months. The first rains usually start a few of the dwarf and tall bearded iris into a premature flowering, this being so regular in the case of the *Iris Kochii* that it is now being sold as a fall bloomer. *I. stylosa* (*I. unguicularis*) also flowers in the fall and early winter, accompanied at the latter time by the smaller bulbous irises, such as *I. reticulata*. From February on, the dwarf bearded irises (*I. pumila* and the many slightly taller forms of *I. Chamæiris*) are covered with masses of flowers in various shades of cream, yellow, blue, and purple. In March and April one has a choice of the tall bearded or so-called German iris, the oncocyclus group, *I. spuria*, *I. ochroleuca*, *I. aurea*, *I. Monnieri*, and their cross-bred relatives, as well as the native Californian species and the moisture-loving Siberians. May sees the Spanish irises at their best, followed toward the end of the month by the English iris, and the season ends in June or July with the big Japanese.

The cultural directions for California are simple, varying somewhat with each main group. The tall bearded varieties grow so easily and are so clean and so nearly evergreen that the type (*I. germanica* and its white form) is often used for planting between sidewalk and curb. Yet the many beautiful kinds to be found in the *I. pallida*, *I. plicata*, *I. neglecta*, *I. variegata*, and *I. squalens* sections are not very often seen, although their culture is quite as easy. All they require is sunlight and a place which becomes quite dry in the summer, the easiest possible conditions to supply in California. They dislike shade and standing moisture. Soil is not important, as equally fine results have been secured in the heavy adobe of the valleys and in gravelly hillside loams. Divide to single rhizomes and replant when they show signs of being crowded. This is best done just after blooming or in late summer, but it is possible at any time of the year.

Next to the above, the bulbous Spanish irises give the best garden effect and lead in usefulness as cut-flowers. The little bulbs should be at least 3 inches underground by October, if possible, as they dry up if left too long before planting. Distance apart is a matter of taste, but they may go as close as 3 inches if space is valuable, and may even be used as a top crop between tulip or daffodil bulbs to keep up the show in a small garden. Plant in any cultivated soil, but see that drainage is good, as the stems rot off if subjected to stagnant water. After blooming, do not cut the stems to the ground if flowers are desired next year, for the slight foliage is needed to ripen the bulbs. Many of the best varieties, however, are so cheap that where ground is valuable they may be discarded after blooming, though if left to ripen properly they will increase so rapidly that division will be necessary every other year. English irises are not nearly so satisfactory, though their flowers are larger. They need much more moisture than the Spanish irises, and are more to be recommended to those who can give plenty of water and partial shade.

The oncocyclus and regelia irises do better in California than anywhere else in America, as they must be dried off in summer and no artificial means are necessary here. Contrary to European practice, the best success is achieved by planting as soon as received in October and encouraging growth so that the plants will be ready to bloom in March and April. No special soil is recommended, but it is desirable to cater to their lime-loving taste by incorporating old plaster and bone-flour in the earth. They are nowhere easy plants to grow, so, if success be achieved the first year, leave the roots alone. Under these conditions, *I. susiana*, *I. atrofusca*, *I. iberica*, *I. Lortetii*, *I. Korolkowii*, and others bloom quite well. The Juno irises do fairly well under these same conditions, but are still rather an experiment.

Most striking features of many gardens in April are huge clumps of *I. orientalis* (*I. ochroleuca*). For culture these can be grouped with *I. spuria*, *I. aurea*, and *I. Monnieri*, as all like lots of water during their growing season, which is fortunately our rainy one, but again somewhat contrary to experience elsewhere they can get through the dry season without irrigation.

The Siberian and Japanese iris, however, need moisture as much here as elsewhere, and, though the amount required may be lessened by heavily mulching the bed with rotten manure, they are certainly less adapted to our natural conditions than the other sections of the genus. In the warmer, sunnier parts of the state, the flowers often burn badly and have to be protected with lath screens, an unsightly arrangement. Their most suitable place is in a Japanese garden where they can get the overflow of a pool, and if this is in the summer-fog belt they are quite satisfactory.

The Californian iris are well worthy of garden cultivation, *I. Douglasiana*, with its range of color from purple through lilac to buff, being especially attractive. Do not dig up the wild plants when in bloom, as they will not move well at that time. Either raise from seed or lift them when growth starts in at the beginning of the rainy season, this being the only safe time to move any of the native species.

Twenty-five distinct tall bearded irises for California, omitting only expensive novelties:

Asiatica (Kharput), amas, Kochii.

Pallida, pallida dalmatica (Princess Beatrice), Albert Victor, Queen of May, Madame Paquette.

Madame Chereau, Mrs. Reuthe.

Mrs. Horace Darwin, Victorine (weak grower), Isolene.

Perfection, Cottage Maid.

Darius, Gracchus, Hector, Mrs. Neubronner.

Jacquesiana, King of Irises.

Cengialtii, florentina, flavescens, cypriana superba.

Sydney B. Mitchell.

Orris-root cultivation.

Orris-root (corruption of *iris-root*) is apparently the product of *I. germanica* and related species; the violet-scented roots are used for perfumery powders, dentrifices, and for bad breath; the "fingers" made from the rhizomes are used for teething babies.

As orris-root is no longer used for artificial violet, the price has receded to normal, and probably if grown in this country would not pay. However, as it is likely to be of interest to the public and experimenters, the following notes are quoted from L. J. Keena, Florence, Italy, in a commercial publication.

"The soil in which this root is grown has much to do with the quality, as well as with the quantity and fragrance of the root, and therefore with its commercial success. This plant grows in different kinds of soil, but that best adapted to its growth is the stony mountain soil. This, however, must be scientifically prepared so that the under soil will not remain compact, for that would be disastrous to the plant during the summer months. In a loose soil containing sand the roots grow well, but are less odorous and compact. Rich yellow soil is still less adapted to its culture, as the plants die quickly. The rich land near manure-piles produces a great quantity of plants, but the roots are neither of good quality nor fragrant, and when dried shrivel up and are consequently discarded by the buyers. The situation or lay of this land matters little, though the best ground is usually found on hillsides. The plant also grows high up in the mountains, where snow and ice make the cultivation of it difficult. In these high places the root takes a few years more to reach its full growth.

"The most suitable soil for orris-root is that which has been prepared by spring seeding with some variety of leguminous plant, and which has been well prepared and deeply plowed. The best months for planting the iris are August and September, although it may be planted as late as the first part of October. The first two months mentioned, however, are preferable for the planting, as the plant begins to grow immediately upon being placed in the ground.

"The best method for planting in soil that has already been prepared is to make holes with a hoe about 16 inches apart, beginning at the bottom of the hill One plant should be placed in each hole resting on the wall of the hole and having its root just reach the bottom. This permits the perfect development of the bulbous root. To insure good production, the soil should be hoed in May and again in September. Irrigation is not beneficial to the plants, as the roots become less compact in irrigated land and there is a dangerous tendency toward fermentation. Fertilizing the soil with manure has the same effect, but if the production of a large number of plants is desired, a system of fertilizing with rich soil can be adopted. The best fertilizer is the seed "lupino" (*Lupinus albus*), which, after being cooked in an oven, is placed in small quantities near each plant at the September hoeing of the first year, if it is to be a two years' growth, and in September of the second year, if for a three years' growth. If the field is to be replanted with orris-root the soil should be well fertilized, and grain, grass or some other crop grown thereon for three or four years.

"The gathering of this product begins during the last fifteen days of June, and is carried on in the following manner: Several men hoe out the plant as a whole, distributing only so many of the plants as can be handled by the rest of the force during the following day, because the plants dry quickly when exposed to the sun and wind. The plants are then carried to a shelter, where the bulbous part of the root is cut off, care being taken to leave enough of the root extensions to insure a good growth for the following years. The bulbous root is then cleaned and scraped free of all imperfections. After the scraping, it is washed by hand in a succession of basins of running water.

"The roots for market are then dried in the sun, with provisions for covering and protecting from the ruinous effects of rain. It is well to set the roots outside before sunrise in order that they may receive the bleaching effect of the dew. After eight days' exposure to a strong sun, the orris-roots can be taken in under cover and packed in a dry place. Preferably the roots should be pulpous and as white as possible. Artificial drying in ovens or in any other manner depreciates the value of the product by making it less than if sun-dried. In the drying process the weight of the root becomes two-thirds of what it was when cut from the plant."

KEY TO THE SUBGENERA.

A. *Rootstock a short, thick, or a slender creeping rhizome.*
  B. *Outer segms. of the perianth distinctly crested on the claw and the lower part of the blade*..... EVANSIA. Species 1–5
  BB. *Outer segms. of the perianth bearded with multi-cellular hairs.*
    C. *Seeds without a conspicuous aril*........... POGONIRIS. Species 6–34
    CC. *Seeds with a conspicuous creamy white circular aril.*
      D. *Aril much smaller than the seeds: lvs. not fully grown at flowering-time*........... PSEUDOREGELIA. Species 35
      DD. *Aril nearly as large as the seed itself: lvs. fully grown at flowering-time.*
        E. *St. 1-headed, 1–3-fld*................ REGELIA. Species 36–38
        EE. *St. 1-headed, 1-fld.: beard diffuse on the claw and the lower part of the blade*......... ONCOCYCLUS. Species 39–51

BBB. *Outer segms. of the perianth without a beard or crest, sometimes pubescent.*
C. *Infl. a regular raceme: seeds conspicuously winged*............PARDANTHOPSIS. Species 52
CC. *Infl. not a regular raceme: seeds not conspicuously winged*...........APOGON. Species 53–85
AA. *Rootstock a bulb.*
B. *Inner segms. of the perianth small, often minute, spreading or deflexed*........ JUNO. Species 86–98
BB. *Inner segms. of the perianth large, erect.*
C. *Stamens not adhering to the style-branches.* XIPHIUM. Species 99–109
CC. *Stamens adhering to the style-branches*...... GYNANDRIRIS. Species 110

SUBGENUS EVANSIA.

A. *St. none or very short, evidently exceeded by the lvs.: plants dwarf.*
B. *Perianth-tube very slender, exceeding the bracts*.................. 1. **cristata**
BB. *Perianth-tube expanded above, not exceeding the bracts*.............. 2. **lacustris**
AA. *St. evident, equaling or exceeding the lvs.: plants large.*
B. *Pedicel much shorter than the spathe*......................... 3. **tectorum**
BB. *Pedicel about as long as the spathe or only slightly shorter.*
C. *Lvs. thin, distinctly ribbed, both surfaces slightly glaucous*....... 4. **Milesii**
CC. *Lvs. thick, smooth, with a glossy upper- and a glaucous under-surface*...................... 5. **japonica**

1. **cristàta,** Soland. Plant dwarf: rhizome slender, creeping: lvs. ensiform, thin, 4–8 in. long, green: st. 1–3 in. high, flattened, 1-headed, bearing 2–3 lvs.: tube slender, 1½–2 in. long; limb blue; outer segms. obovate, 1–1½ in. long, crested; inner segms. shorter, naked. April, May. Mountains of Ky., Va., and the Carolinas. B.M. 412. Gn. 45, p. 127. L.B.C. 14: 1366.

2. **lacústris,** Nutt. Similar to *I. cristata* in size and foliage except that the lvs. are rather narrower and sometimes wavy margined and the perianth-tube is only ½–1 in. long, shorter than the spathe-valves: fls. blue; segms. expanded above: caps. ovoid, borne on a pedicel of about its own length. Shores of Lakes Huron, Michigan, and Superior.

3. **tectòrum,** Maxim. (*I. chinénsis,* Bunge. *I. cristàta,* Miq. *I. fimbriàta,* Klatt). Fig. 1965. Lvs. 1 ft. long, ensiform, thin, strongly ribbed: st. 1½ ft., subterete: heads on long peduncles; tube 1 in. long; limb bright lilac; outer segms. 2 in. long, obovate; claw half as long as the blade, streaked with violet, with a wavy edge and a large, laciniate, white and lilac crest running up the claw and half up the blade; inner segms. spreading, nearly as large, plain lilac, short-clawed. Sent to Eu. in 1872 by Dr. Hance. Cult. in China and Japan. B.M. 6118. F.S. 22:2282. Gt. 716. Gn. 50:272. G.C. III. 35:355; 44:142. J.H. III. 44:146. G.L. 17:348. Var. **álba,** Dykes (*I. tectòrum* var. *cándida,* Hort.). Fls. pure white, with few faint yellow veins at the base of the segms. Comes true from seed. Gt. 57: 1571. Gn. 70, p. 15. G.C. III. 40:216. G.W. 10:525.

1965. Iris tectorum. (×¼)

4. **Milesii,** Foster. Lvs. 7–8 on the st., 2–3 ft. long and 2–3 in. broad, thin, strongly ribbed: st. 2–3 ft. high, branched, bearing 4–5 heads: fls. bright lilac, lasting only a day; outer segms. oblong-cuneate, claret-purple, whitish in the center, spotted and veined with lilac, furnished with a deeply laciniated yellow crest; inner segms. oblong, spreading; style-crests deeply toothed. Himalayas. B.M. 6889.—Near *I. tectorum,* but inferior.

5. **japónica,** Thunb. (*I. chinénsis,* Curt. *I. fimbriàta,* Vent.). Fig. 1966. Lvs. ensiform, thick, smooth, 1–1½ ft. long: st. slender, as long as the lvs., with a raceme of lilac fls.: tube ¾in. long; outer segms. 1–1½ in. long, with crimped margins, yellow on the claw, crested; inner segms. smaller. Winter. Japan and China. B.M. 373. Gt. 511. Gn. 28:120; 77, p. 142. J.H. III. 31:185. A.G. 12:704. F.R. 2:149.—An evergreen greenhouse plant except in Calif. where it does very well outdoors in a shady border.

SUBGENUS POGONIRIS.

A. *Plants dwarf: lvs. generally less than 9 in. long.*
B. *Tube of the perianth 1 in. or more in length.*
C. *St. obsolete or very short*......... 6. **pumila**
CC. *St. present, 1–10 in. long.*
D. *Spathe-valves not keeled or only the outer one slightly keeled.*
E. *The st. almost entirely hidden by clasping lvs.*
F. *The spathe-valves lanceolate, membranous, green*.. 7. **pseudopumila**
FF. *The spathe-valves oblong, green or scarious above*... 8. **biflora**
EE. *The sts. bare above, with 1–2 reduced lvs. below the center.* 9. **Chamæiris**
DD. *Spathe-valves acutely keeled*....10. **Reichenbachii**
(See also I. imbricata No. 22)
BB. *Tube of the perianth short or none.*
C. *Spathe-valves green or only partly scarious.*
D. *Rhizome slender, stoloniferous: sheaths splitting into fibers*....11. **flavissima**
DD. *Rhizome more compact: sheaths not splitting into fibers*......12. **mandshurica**
CC. *Spathe-valves scarious, even in the bud*........................13. **Cengialti**
AA. *Plants tall: lvs. generally more than 1 ft. long.*
B. *St. scarcely overtopping the lvs.*
C. *The st. branched below the middle*........................14. **aphylla**
CC. *The st. branched above the middle, or unbranched.*
D. *Spathe-valves wholly green when the first fls. open, often flushed with purple, inflated*.........15. **variegata**
DD. *Spathe-valves partly scarious when the first fls. open.*
E. *Fls. dull purple*............16. **lurida**
EE. *Fls. dark violet*.............17. **Kochii**
DDD. *Spathe-valves entirely scarious at flowering-time*...........18. **atroviolacea**
BB. *St. much overtopping the lvs.*
C. *Spathe-valves entirely scarious at flowering-time or even in the bud.*
D. *Fls. pale purple or lilac*.......19. **pallida**
DD. *Fls. white; segms. veined and flushed with purple or lilac on the margins.*
E. *Sts. 2–3 ft. high*............20. **plicata**
EE. *Sts. 1–1½ ft. high*..........21. **Swertii**
CC. *Spathe-valves green or partly scarious.*

D. *Fls. yellow.*
E. *The spathe-valves membranous, much inflated, almost wholly green*.............22. **imbricata**
EE. *The spathe-valves firm, not inflated, almost wholly scarious*...................23. **flavescens**
DD. *Fls. purple, violet, lilac, or white; inner segms. sometimes yellowish.*
E. *Spathe-valves much inflated*..24. **Alberti**
EE. *Spathe-valves scarcely inflated.*
F. *Lateral heads subsessile*...25. **florentina**
FF. *Lateral heads stalked.*
G. *The spathe-valves narrow acuminate, almost wholly green, scarious only at the tip and edges*..............26. **Biliottii**
GG. *The spathe-valves narrow acuminate, scarious in the upper half and much tinged with purple*.................27. **trojana**
GGG. *The spathe-valves broad, navicular, not tinged with purple.*
H. *Lvs. glaucous, broad*..28. **Junonia**
HH. *Lvs. slightly glaucous, blue-green, comparatively narrow*....29. **cypriana**
GGGG. *The spathe-valves broad, navicular, much tinged with purple*..........30. **germanica**

The following four forms cannot be separated from each other and from some of the foregoing forms by strictly botanical characteristics. They are probably varieties of hybrid origin as indicated in the descriptions.

Outer segms. blue to pale violet or white; inner segms. white...............31. **hybrida**
Outer segms. blue to bright lilac; inner segms. lighter....................32. **neglecta**
Outer segms. blue-purple with faint darker veins; inner segms. smoky yellow and pale purple...........33. **sambucina**
Outer segms. lilac-purple; inner segms. smoky yellow and pale lilac.......34. **squalens**

6. **pùmila,** Linn. (*I. violàcea,* Sweet. *I. taùrica,* Lodd. *I. cærùlea,* Spach). Fig. 1967. Lvs. linear, 2–4 in. long: st. none or very short, 1-headed: spathe-valves scarious at the tip: fls. fugitive, yellow, or bright or dark lilac; limb 2 in. long. Austria–Hungary, Asia Minor, S. Russia. L.B.C. 16:1506, 1574. R.H. 1903:132. G.M. 49:225 (var. *bicolor*); Gn. M. 15:360.—A dwarf, hardy plant, spreading rapidly in borders. Has many color varieties ranging from dark reddish purple to light purple and yellow. Var. **áttica,** Boiss. & Heldr. (*I. áttica,* Boiss. & Heldr.). Lvs. narrow, falcate: fls. pale straw-yellow tinged with green; segms. with inconspicuous purplish veins, the outer with a purplish or greenish brown patch. Gt. 11:377. Var. **violàcea,** Ker. Fls. bright blue. B.M. 1261. Var. **lùtea,** Ker. Fls. pale yellow. The common yellow form. B. M. 1209. —The following trade names which are self-explanatory have been applied to some of the numerous color-varieties of this species: *I. alba, I. atropurpurea, I. atroviolacea, I. azurea, I. bicolor, I. cælestis, I. lutea, I. sulphurea. I. gracilis,* E. Berg, is probably a hybrid of this species.

7. **pseudo-pùmila,** Tineo (*I. panormitàna,* Tod.). Lvs. ensiform, glaucescent, 6–9 in. long, narrowed suddenly to an oblique tip: st. 1-headed, 6–8 in. long, clothed with bracts, 1-fld.: tube 2–2½ in. long; spathe-valves green: fls. varying from yellow to bright lilac; outer segms. oblong unguiculate, 2–2½ in. long; inner segms. rather broader. Mountains of Sicily. *I. Státellæ,* Tod., is a hybrid or a sport of this species. The seeds give rise to typical *I. pseudo-pumila* plants. B.M. 6894 is *I. erratica,* Tod. Probably a similar hybrid.

8. **biflòra,** Linn. (*I. subbiflòra,* Brotero. *I. fràgrans,* Salisb. *I. nudicaùlis,* Hook.). Lvs. 6–9 in. long: st. 2–10 in. long, compressed, usually bearing 2–3 small clasping lvs. which entirely hide it: fls. bright violet-purple; outer segms. obovate-cuneate, 2–2½ in. long, with dark veins and a beard of long, yellow hairs; inner segms. obovate, unguiculate, lighter, with faint veins. Portugal and N. Morocco. B.M. 1130.

1966. Iris japonica (×⅓). No. 5.

9. **Chamæìris,** Bertol. (*I. olbiénsis,* Henon. *I. lutéscens,* Lam. idem, Delarb. *I. viréscens,* Delarb.). Lvs. 3–6 in. long, ½in. broad: st. 1–10 in. long, bare above with 1–2 reduced lvs. below the middle: fls. bright yellow; outer segms. obovate-cuneate, tinged and veined with brown; inner segms. oblong. May. Italy, France. B.M. 2861, 6110. Gn. 63, p. 26.—Distinguished from *I. pumila* by the evident st., the shorter tube, and the more inflated and less membranous spathe-valves. Var. **itálica,** Parl. Fls. dark violet.

10. **Reìchenbachii,** Heuffel. (*I. bosnìaca,* Beck. *I. balkàna,* Janka. *I. Reichenbachiàna,* Baker). Rhizome stout; tufts crowded: lvs. 3–6 in. long, ¼–¾in. wide, increasing in size after flowering-time: st. 6–10 in. long, 1-headed, bearing 1–2 reduced lvs.: spathes 1–2-fld., 1½–2 in. long; valves ventricose, green, or slightly scarious: fls. reddish brown-purple with bluish white beard, or yellow with orange beard; outer segms. obovate, cuneate, 2 in. long, 1 in. broad; inner segms. oblong-elliptical, emarginate, suddenly constricted to a canaliculate claw. Bosnia and Herzegovina to Bulgaria and Macedonia.—Resembles *I. Chamæiris,* but differs in the flattened, acutely keeled spathes and the thin texture of the fls. The yellow-fld. forms are often slightly veined with purple.

11. **flavíssima,** Pall. (*I. arenària,* Waldst.). Lvs. thin, linear, 4–8 in. long: st. 1–6 in. long, 2–3-fld.: limb bright yellow; outer segms. 1–1½ in. long, ¾in.

broad; inner segms. oblong, narrower. Hungary, N. E. Asia and Altai region to Mongolia. B.R. 549. G.C. III. 29:337.—*I. arenaria* is the Hungarian representative of *I. flavissima*. It is smaller than *I. flavissima*, but otherwise scarcely distinct. Var. **Bloudòwii,** Ledeb. (*I. Bloudòwii,* Ledeb.). More robust with broader lvs., a longer st. and larger fls. Gt. 29:1020. Turkestan, Siberia and China. Var. **minor,** Hort. Smaller.

12. **mandshùrica,** Maxim. Lvs. from a short creeping rhizome whose sheaths are not split into fibers, ensiform, 6–8 in. long, ½in. broad: st. 1-headed: spathe 2-fld.; valves 1½–2 in. long, membranous, green with a scarious edge: pedicel short: fls. yellow; tube ½in. long; outer segms. 1½–2 in. long, ½in. broad, obovate-cuneate, truncate, with a yellow beard; inner segms. narrower and shorter; crests of style-branches obtuse, dentate. S. Manchuria.—Near *I. flavissima,* from which it is distinguished by the more compact rhizome and wider lvs.

13. **Céngialti,** Ambrosi. Lvs. ensiform, yellowish green, glaucous, 6 in. long, ½in. broad: sts. 6–12 in. long, usually exceeding the lvs., 1–3-headed: spathes 2-fld., 1 in. long, brown-scarious in the bud but not silvery white like those of *I. pallida:* fls. bright lilac; outer segms. obovate-cuneate, veined with brown-purple on the pale claw, with a beard of white orange-tipped hairs; inner segms. obovate, short-clawed. Lombardy, S. Tyrol.—A dwarf species closely allied to *I. pallida.*

14. **aphýlla,** Linn. (*I. bohèmica,* Schmidt. *I. hungárica,* Waldst. & Kit. *I. furcàta,* Bieb. *I. falcàta,* Tausch. *I. Fièberi,* Siedl. *I. nudicaùlis,* Hook. *I. benacénsis,* Kerner). Lvs. glaucescent, 6–12 in. long: st. equaling the lvs., sometimes forked low down, leafless: spathe-valves greenish, tinged with purple: fls. dark lilac; outer segms. obovate-cuneate, 2–2½ in. long; beard white; inner segms. broader, obovate. E. Eu. B.M. 2361, 5806. B.R. 801. L.B.C. 20:1970.—The plant commonly cult. as *I. gracilis* is probably *I. aphylla.*

15. **variegàta,** Linn. Lvs. 1–1½ ft. long: st. equaling the lvs.: outer segms. oblong-cuneate, claret-brown toward the tip, much veined with brown on a yellow ground; beard bright yellow; inner segms. erect, oblong, bright yellow, veined. Austria, Turkey and S. Russia. Long in cult. B.M. 16. Gn. 14:12; 52:364 (var. *aurea*). G.M. 54:126. Var. **honorábilis,** Hort. Yellow, shaded with brown.

16. **lùrida,** Soland. Lvs. 1 ft. long, slightly glaucous: st. not much overtopping the lvs., 3–4-headed: spathe-valves green flushed with purple, scarious above, very ventricose, not keeled: outer segms. obovate-cuneate, reflexed from half-way down, dead purple at the top, veined with dull purple on a yellowish ground below; beard yellow; inner segms. broader, dull purple. S. E. Eu. B.M. 986, also B.M. 669, which is probably a different plant.

17. **Kòchii,** Kerner. Lvs. 12–15 in. long, glaucescent: st. as long as the lvs., 3–4-headed: spathe-valves lanceolate, the outer herbaceous; the inner partly scarious, tinged with purple along the edge: outer segms. obovate, with a broad cuneate claw, 3½–4 in. long, 1¾ in broad, dark violet; claw veined with brown; beard yellow; inner segms. broadly obovate, clawed, dark violet, somewhat lighter than the outer. Istria, near Trieste and Rovigno.—Probably a form of *I. germanica* or a hybrid between that species and *I. aphylla.*

18. **atroviolàcea,** Lange. Lvs. very glaucous, 1 ft. long: st. equaling the lvs.: spathe entirely scarious: fls. dark violet, very fragrant; outer segms. obovate-cuneate, 3 in. long; beard white, tipped with yellow; inner segms. as long, 2 in. broad, orbicular. Late May.—Known only in cult. Probably either *I. germanica* var. *atropurpurea* or *I. Kochii.*

19. **pállida,** Lam. (*I. asiática,* Stapf. *I. sícula,* Tod.). Lvs. 1–2 ft. long: st. much exceeding the lvs., 2–3 ft. high: spathe-valves wholly scarious before the fls. expand: fls. fragrant, violet, rarely white; outer segms. obovate-cuneate, 3½ in. long; inner segms. orbicular. Crete, Rhodes, Syria, Palestine. B.M. 685. Gn. 33:32; 50, p. 119. G.M. 38:441. G. 29:179. G.L. 23:147. J.H. III. 54:437 (var. *delicata*). R.B. 30:145 (variety with variegated lvs.).—The spathe-valves entirely scarious even in the bud, the more complicated infl. and the fragrant fls. distinguish this species from *I. germanica.* Var. **dalmática,** Hort. Lvs. 2 in. wide, broader than those of the type, very glaucous: st. shorter and stouter than that of the type: fls. lilac-purple. The finest form of *I. pallida.* J.H. III. 56:545. Var. **speciòsa,** Hort. Tall, with large, light blue fls.

20. **plicàta,** Lam. (*I. aphýlla,* Hort., not Linn. *I. aphýlla* var. *plicàta,* Ker). Rhizome, st. and lvs. as in *I. pallida:* outer segms. obovate, pure white in the center, conspicuously veined with lilac toward the margin and on the claw; inner segms. very plicate, white tinged with lilac on the margin. B.M. 870.—Known only in cult. Probably derived from *I. pallida.*

21. **Swértii,** Lam. (*I. aphýlla* var. *Swértii,* Ker.) Much dwarfer than *I. florentina* and *I. pallida.* St. 1–1½ ft. long: spathe-valves flushed with violet: outer segms. 2–2½ in. long, obovate-cuneate, white, faintly veined and flushed with purple on the margin; inner segms. as large, much crisped, pure white, except the purple keel and margin.—Fragrant. Known only in cult.

22. **imbricàta,** Lindl. (*I. flavéscens,* Sweet. *I. obtusifòlia,* Baker). Lvs. about 6 in a tuft, broadly ensiform, pale green, 6–8 in. long at flowering time: st. 12–20 in. long, bearing a terminal and several nearly sessile lateral clusters each subtended by a ventricose navicular bract: spathe-valves oblong navicular, 2–3 in. long, green, membranous, very ventricose: fls. greenish yellow; tube 1 in. long; outer segms. obovate-cuneate, 2 in. long and 1 in. broad, veined with brown on the claw; inner segms. erect, rounded oblong, subcordately unguiculate, mottled with brown on the claw. Transcaucasia and N. Persia. B.R. 31:35. B.M. 7701.—Confused with *I. flavescens,* from which it differs by the membranous inflated green spathe-valves.

1967. **Iris pumila.** One of the best dwarf species (×⅓). No. 6.

23. **flavéscens,** DC. Lvs. 12–15 in. long: st. 2–3 ft. high, bearing 3–4 heads: spathes 2–3-fld., not entirely

scarious at flowering-time: fls. bright lemon-yellow; outer segms. obovate-cuneate, 2½ in. long; beard deep yellow; inner segms. obovate, pale yellow. G.C. III. 48:95.—Known only in cult.

1968. Iris germanica. Typical of many species in which the beard is confined to the midrib. (×⅙)

24. **Álberti,** Regel. Lvs. ensiform, glaucous, 1½–2 ft. long: st. exceeding the lvs., bearing 5–6 heads in a loose panicle: spathe-valves mostly green, very slightly scarious at tips: outer segms. obovate-cuneate, 2 in. long, bright lilac, with a rudimentary crest and a dense beard of white, yellow-tipped hairs, veined; inner segms as long and broader than the outer, with convolute claws, lilac. Discovered in Turkestan by Dr. Albert Regel. Gt. 999. B.M. 7020.

25. **florentìna,** Linn. Rhizome fragrant when dried (orris-root): lvs. 1–1½ ft. long: st. exceeding the lvs.: fls. white; outer segms. 3½ in. long, tinged with lavender; claw yellowish veined with purple; inner segms. as large, white. Cent. and S. Eu. B.M. 671. Gn. 16:82; 51, p. 295. G.M. 54:127. —Flowers early, with *I. germanica.* Hardy. Var. **álbicans,** Lange (*I. álbicans,* Lange. *I. florentìna* var. *álba,* Hort.). Pure white. Spain to Cyprus. Var. **Madónna,** Hort. Fls. blue; spathe-valves flushed with purple.

26. **Bilióttii,** Fost. Lvs darker green, more distinctly striated, and more rigid than in *I. germanica,* about 20 in. long, 1½–1¾ in. broad: st. several-headed, 2½–3 ft. long: spathe-valves narrow, acuminate, nearly 2 in. long, ventricose, scarious only at the tips: outer segms. obovatc-cuneate, reddish purple, with many dark veins; beard white, tipped with yellow; inner segms. orbicular unguiculate, 2 in. broad, bright blue-purple. Late June. Trebizond.—Very near *I. germanica.*

27. **trojàna,** Kerner. Lvs. very acute, glaucescent: st. over 3 ft. high, much branched and overtopping the lvs.: pedicel none: fls. bright violet-purple; outer segms. obovate; blade longer than the claw; claw white, bordered with yellow and veined with brown-purple; inner segms. elliptic, suddenly narrowed to a claw; style-crests broad, denticulate. Troad, Asia Minor. G.C. III. 53:170.

28. **Junònia,** Schott & Klotschy. Rhizome stout, compact: lvs. 12–14 in. long, 1¾ in. wide, glaucous: st. 20–24 in. high, bearing a terminal head of 2 fls. and 4 lateral branches, the lowest about 3–4 in. long: spathe 1½ in. long, with pale green valves, scarious in the upper half: pedicel none: outer segms. obovate-cuneate, purple-violet, whitish at the throat and on the claw, veined with yellowish brown; inner segms. obovate, abruptly unguiculate, pale violet, veined and spotted with red-brown on the paler claw. Cilician Taurus.—Differs from *I. pallida* in the spathe-valves, which are only partly scarious at flowering-time.

29. **cypriàna,** Foster & Baker. Plants tall, the branching st. being 3 ft. high, bearing many fls. 6–7 in. diam.: outer segms. obovate-cuneate, reddish lilac, with thin, darker veins; claw whitish, with greenish brown veins; inner segms. oblong-unguiculate, lilac, spotted with reddish brown on the claw. June, July. Cyprus.—Very near *I. pallida,* from which it differs only by the longer navicular spathe-valves, which are not entirely scarious at flowering-time, and the more obovate segms.

30. **germánica,** Linn. Fig. 1968. Lvs. 1–1½ ft. long: st. 2–3 ft. high, usually with a 2-fld. terminal head and one short and one longer lateral branch, each bearing a single fl.: spathe-valves tinged with purple, scarious in the upper half: outer segms. obovate-cuneate, 2–3 in. long; beard yellow; inner segms. as large, obovate, connivent. Cent. and S. Eu. Early May, June. B.M. 670. B.R. 818. I.H. 40: 182 (var. *Gypsea,* pure white). Gn. 48:242 (dark purple var.). Gn. M. 15:362. Var. **reticulàta supérba,** Hort. Outer segms. purple, veined; inner segms. lavender. Var. **nepalénsis,** Dykes (*I. nepalénsis,* Wallich. *I. germánica* var. *atropurpùrea,* Hort.). Purple King. Fls. red-purple; outer segms. darker, almost black-purple.

31. **hýbrida,** Retz. (*I. amæ̀na,* DC.). Differs from *I. neglecta* by its longer spathe-valves, and its pure white or faintly lilac-tinted outer segms. and style-branches. June.—Known only in cult.

32. **neglécta,** Hornm. Lvs. slightly glaucous, 12–15 in. long, ensiform, purple at the base: st. taller, 1½–2 ft., many-fld.: spathe-valves green below at flowering-time, much tinged with purple: outer segms. obovate-cuneate, very obtuse, 2 in. long, violet-blue on the margin, whitish veined with blue in the center; beard yellow; inner segms. erect or connivent, oblong, as large as the outer, pale lilac. June. B.M. 2435.—Known only in cult. Probably a hybrid between *I. pallida* and *I. variegata.*

33. **sambùcina,** Linn. Differs from *I. squalens* in its less robust habit, narrower segms. and elder-like odor. The outer segms. are colored and veined with claret not lilac-purple; inner segms. emarginate. Late May. Cent. Eu. B.M. 187. (According to Dykes this figure is probably *I. squalens,* while plate 787, *I. squalens,* probably represents *I. sambucina.* Both forms are very likely hybrids between *I. pallida* and *I. variegata.*)—Tall and handsome.

34. **squàlens,** Linn. Lvs. glaucous, 1–1½ ft. long: st. 2–3 ft. high, much branched and many-fld.: spathe-valves subscarious: outer segms. obovate-cuneate, upper part plain lilac-purple; claw yellow, veined with lilac; beard yellow; inner segms. as large, obovate, dull lilac and yellow, or brownish and yellow. Cent. Eu. to Caucasus. B.M. 787. (See note under *I. sambucina.*) J.H. III. 48:481.—Many of the German irises of cultivators belong to this form. Var. **Jacquesiàna,** Hort. Outer segms. dark red-violet, yellow at base; inner segms. tawny yellow. Late. One of the best.

SUBGENUS PSEUDOREGELIA.

35. **sikkiménsis,** Dykes. Lvs. 4–8 in. long at flowering-time, later 12–18 in. long, ½–¾in. wide, pale green, ensiform: st. 4–6 in. long, bearing a single head of 2–3 fls.: spathes 2–3 in. long, lanceolate; valves scarious in the upper one-third and along the edges, keeled: tube 1½–2 in. long; outer segms. obovate, contracted to a cuneate claw, 2½ in. long, 1 in. broad, dark lilac, mottled with a deeper shade; beard of white orange-tipped hairs; inner segms. spreading, with an oblong, deeply emarginate blade suddenly contracted into a canaliculate claw, pale lilac; faintly mottled with a deeper shade at the base; style-crests triangular, revolute. Probably from Sikkim.

SUBGENUS REGELIA.

A. *Rhizomes wide-spreading, stoloniferous* . . 36. **stolonifera**
AA. *Rhizomes compact.*
  B. *Lvs. ensiform: outer segms. suddenly contracted into a claw* . . . . 37. **Korolkowi**
  BB. *Lvs. linear: outer segms. gradually narrowed to a claw* . . . . 38. **darwasica**

36. **stolonífera,** Maxim. (*I. Lèichtlinii,* Regel. *I. vàga,* Foster). Rhizome slender, wide-creeping: lvs. in tufts, not contiguous, ensiform, 1–1½ ft. long, scarcely glaucous: st. 1–2 ft. long, almost wholly concealed by clasping lvs., 1-headed, bearing 2–3 fls.: outer segms. 2–2½ in. long, oblong-cuneate, bright lilac, suffused with bronze toward the margin, with a yellow beard; inner segms. oblong, as broad as the outer, claw also bearded. Turkestan. Gn. 52:222. B.M. 7861. Gt. 36:1244 (rootstock only). G.C. III. 32:242. Gn.W. 24:382. Var. **vàga,** Foster, has larger fls.

37. **Korólkowi,** Regel. Rhizome short-creeping: lvs. glaucous, 1 ft. long: st. 1 ft. long, bearing 2–3 reduced lvs. and a single head of 2–3 fls.: spathe-valves 2–3 in. long, keeled, acuminate, green flushed with purple: limb 2½–3 in. long, pale yellowish white, veined with red-brown in the type; outer segms. oblong, 1 in. broad, with a brown beard and a brown patch on the throat; inner segms. as large, erect. May. Turkestan. B.M. 7025. Gn. 28:484. G.C. III. 4:37. Gt. 22:766; 40:1358.—Very hardy. One of the earliest. Variously colored lilac, and so on in cult. Var. **cóncolor,** Foster. Purplish lilac, veined darker. Var. **Leichtliniàna,** Foster. Creamy white, with brownish veins. Var. **violàcea,** Foster. Violet, with dark veins.

38. **darwásica,** Regel (*I. Suwórowi,* Regel. *I. lineàta,* Foster). Lvs. thin, linear, 1 ft. long, ½in. wide, very glaucous, bluish green: st. 1 ft. high, bearing 2–3 reduced lvs. and a single head of fls.: spathe-valves 3–3½ in. long, green or slightly flushed with purple, sharply keeled and very pointed, longer than the tube: outer segms. oblong-cuneate, ½in. broad, 2 in. long, closely veined with oblique lines of claret-purple on a greenish yellow ground; beard blue; inner segms. oblong, with a long claw, often faintly bearded, veined and tinted on the margins with claret-purple. Bokhara. B.M. 7029. Gt. 36:1244.

SUBGENUS ONCOCYCLUS.

A. *Outer segms. of the perianth ligulate, much reduced* . . . . 39. **paradoxa**
AA. *Outer segms. of the perianth not much smaller than the inner.*
  B. *Lvs. linear, narrow, not over ½in. wide, more or less falcate: plant slender: st. usually not over 6–8 in. high.*
    C. *The outer segms. deflexed from the base, very concave* . . . . 40. **iberica**
    CC. *The outer segms. deflexed from the middle, convex.*
      D. *Fls. uniformly colored, not conspicuously veined,*
        E. *Signal patch darker, but of the same color as the outer segms.*
          F. *Color of fls. yellow* . . . . 41. **urmiensis**
          FF. *Color of fls. reddish purple* . 42. **Barnumæ**
          FFF. *Color of fls. lilac* . . . . 43. **Mariæ**
        EE. *Signal patch not of the same color as the outer segms.; fls. purplish black* . . . . 44. **atropurpurea**
      DD. *Fls. conspicuously veined on a ground of different color.*
        E. *Outer segms. obovate-cuneate.* 45. **Saarii**
        EE. *Outer segms. lanceolate pointed* . . . . 46. **Ewbankiana**
  BB. *Lvs. ensiform or linear, over ½in. broad, scarcely falcate: plant larger, stout: st. usually a foot or more high.*
    C. *Inner and outer segms. similarly colored.*
      D. *Fls. light-colored gray or lilac.*
        E. *Outer segms. marked with numerous fine purple veins and sprinkled with minute purplish dots more crowded on the throat; fls. very large* . . 47. **Gatesii**
        EE. *Outer segms. dotted and veined with crimson or reddish brown, with a reddish patch at the throat:; fls. smaller* . . . . 48. **Lortetii**
      DD. *Fls. dark-colored, mostly brownish or purple.*
        E. *Segms. almost uniformly dark purple* . . . . 49. **atrofusca**
        EE. *Segms. heavily veined and spotted with black-brown on a lighter ground* . . . . 50. **susiana**
    CC. *Inner segms. blue to pale blue; outer segms. densely spotted and veined with purple-brown* . . . . 51. **Bismarckiana**

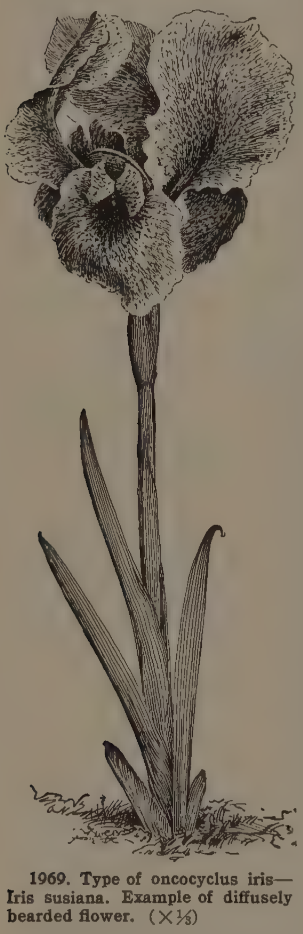
39. **paradóxa,** Stev. Plants dwarf: lvs. linear, 3–6 in. long: st. 2–6 in. high: fl. large; outer segms. reduced to a mere claw, dark, covered with a dense pile; inner segms. 2 in. long, orbicular, lilac to white. Mountains of Ga. and N. Persia. B.M. 7081. Gn. 32:584; 46, p. 173; 59, p. 248 (var. *choschab*). Gt. 386. G.C. III. 29:104 (var. *choschab*).—A fl. with singular combinations of color. Grows in dry situations, but requires shelter in winter. Long cult., but not common.

40. **ibèrica,** Hoffm. Dwarf, with a large fl.: lvs. 3–6 in. long, narrow, very falcate: st. 3–4 in. long outer segms. rounded-obovate, 2 in. broad, pale bro closely veined and blotched with purple-brown a with a shining dark patch on the throat; inner seg

connivent, pure white, faintly veined, with a few wine-red spots at base. Caucasus and mountains of Armenia and Persia. B.M. 5847. Gt. 386 and 713. F.S. 19: 1963. R.H. 1873: 370. Gn. 10:526; 43, p. 131; 72, p. 349. I.H. 19:106. G.C. II. 11:693; III. 53:399. F. 1873:25. F.M. 1875:168.—Hardy. The color of the fls. varies considerably in this species. In some the inner segms. are nearly white, while in others they are nearly as dark as the outer. The species is chiefly distinguished by the curious spoon-shaped concave outer segms. and the depressed style-branches which give the fls. an appearance different from the other members of this group.

41. **urmiénsis,** Hoog (*I. chrysántha,* Baker). Rhizome short-creeping: lvs. linear, 1 ft. long, thick and firm, glaucescent with a pale margin: st. slender, as long as the lvs.: spathe-valves lanceolate-acuminate, 4 in. long, pale green, chartaceous: fls. pale yellow; outer segms. oblong, emarginate, 3 in. long, reflexed from near the base, with a bright orange beard; inner segms. erect, obovate-cuneate, as long as the outer and broader; style-branches yellow, an inch broad, with large quadrate entire crests. Probably near Lake Urumiah in N. W. Persia. B.M. 7784. Gn. 58, p. 375. G.C. III. 28:373.

42. **Bárnumæ,** Baker & Foster. Lvs. about 5–6 in a tuft, slender, linear, about 6 in. long, less than ½in. broad: st. 2–6 in. long, bearing a single sheathing lf.: spathe-valves 2 in. long, green with purple tips and margins: outer segms. obovate-cuneate, reflexed, 2 in. long, 1 in. broad, passing into a cuneate claw, dark reddish purple with darker veins and a triangular beard of yellow purple-tipped hairs; inner segms. obovate-orbicular, connivent, 3 in. long, 2½ in. broad, suddenly contracted into a short claw, reddish purple, lighter than the outer segms. and with more conspicuous veins and few scattered hairs on the claw. Mountains of Armenia. B.M. 7050.



1969. Type of oncocyclus iris—Iris susiana. Example of diffusely bearded flower. (×⅓)

43. **Màriæ,** Barbey (*I. Hélenæ,* Barbey). Lvs. very falcate, 3–4 in. long: st. 3–6 in. long, with 2–4 short lvs.: limb pale lilac, with fine red-brown veins; outer segms. orbicular, 2½ in. long, with a dark purple patch at the throat; inner segms. larger, more rounded. Desert between Egypt and Palestine. Discovered 1880. Gt. 42, p. 488; suppl. pl. J.H. III. 28:302. G.M. 37:215.

44. **atropurpùrea,** Baker (*I. Éggeri,* Hort.). Lvs. 6 in. long: st. 6–8 in.: outer segms. oblong, 2 in. long, purplish black, without veins, with a yellow patch on the throat and a beard of yellow, black-tipped hairs; inner segms. larger, of the same color, with discernable veins; style-crests small. Easily distinguished by its rather small, uniformly colored fls. Gt. 40:1361; 42, p. 489; suppl. pl.

45. **Saàrii,** Schott (*I. Sàri,* Aut. *I. lupìna,* Foster). Rhizome short, stout: lvs. about 6 in. long, finally 1 ft., linear-complicate: st. 3–6 in. long, with 2 reduced lanceolate lvs.: pedicel very short: fls. bright lilac, large as in *I. susiana;* tube 1 in. long; outer segms. obovate-cuneate, 1½–2 in. broad, reflexed from half way down; inner segms. oblong, with a short claw. Very near *I. iberica,* from which it differs chiefly by its bright lilac fls. Asia Minor. B.M. 7904. G.C. III. 36:147. Var. **lùrida,** Boiss. Segms. brownish white with many brown-black spots near the center, and numerous brownish lines toward the margin, the outer with a brown-black spot at the throat. Gn. 43:130; 54, p. 59.

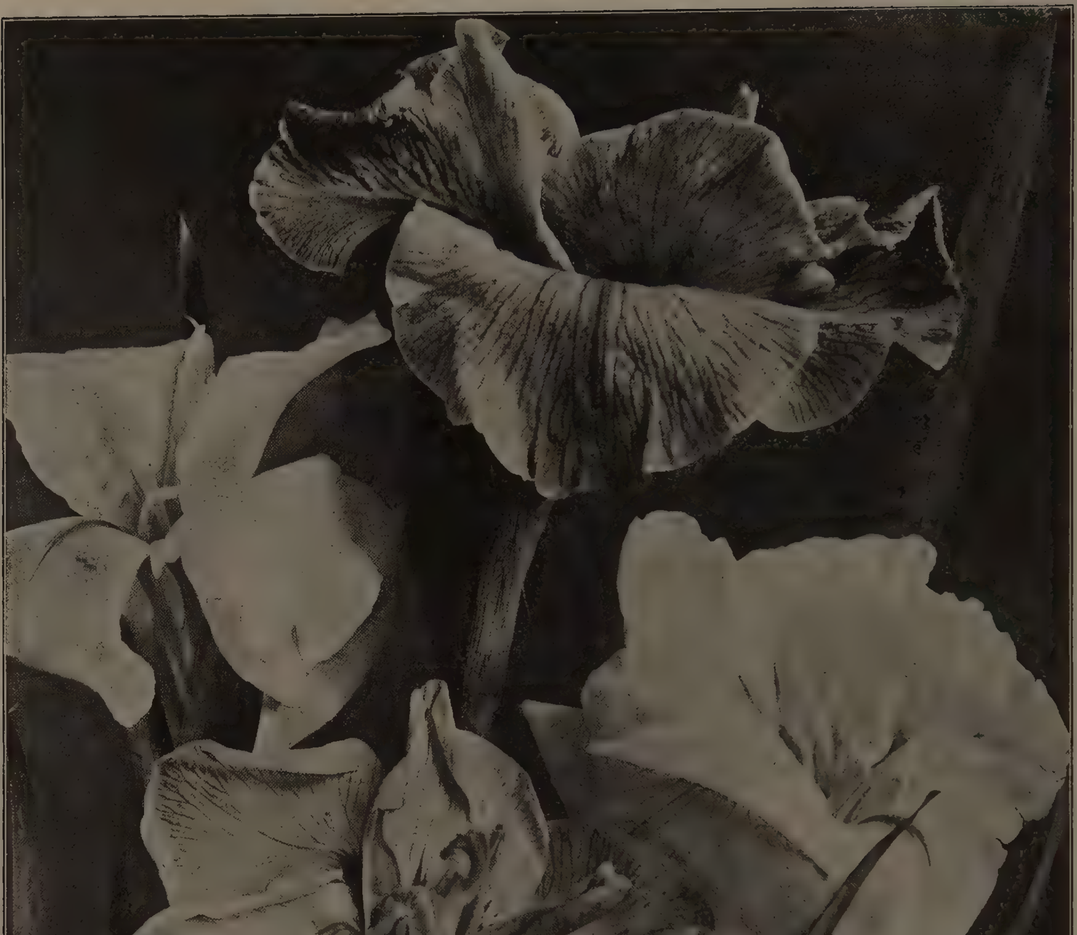
46. **Ewbankiàna,** Foster (*I. Spréngeri,* Siehe). Rhizome slender, similar to that of *I. iberica:* lvs. 6–8 in. long, glaucous, very narrow and somewhat falcate: st. 2–4 in. high, bearing 2–3 reduced lvs.: spathe 1-fld., 2¼ in. long; valves narrow, inflated, green: outer segms. lanceolate, pointed, horizontally extended, not recurved, creamy or grayish white, marked with conspicuous, irregular, jagged, purple-brown veins, with a purplish black patch at the throat; beard of stout yellow hairs tipped with brown; inner segms. ovate-lanceolate colored like the outer and marked with jagged brown-purple veins which become more broken on the claw; style-branches almost uniform chocolate-brown. Mountains of Persia and Transcaucasia. R.H. 1901, p. 399. Gn. 70, p. 15. G.C. III. 29:407; 36:50. —The venation, together with the ground-color, gives the fls. at a distance a uniform gray tone. Not particularly beautiful.

47. **Gàtesii,** Foster. Habit and foliage of *I. susiana:* outer segms. orbicular, 3–5 in. broad, cream-white, sometimes sky-blue, covered with a network of fine veins, giving them a light gray tint; inner segms. larger, pale purple or yellow. Dry regions, Armenia. B.M. 7867. Gn. 43:130 and p. 131; 52, pp. 88, 279; 72, p. 422. G.C. III. 8:17. A.G. 13:60. G. 20:299.—The largest-fld. of its subgenus. Fls. about twice as large as in *I. susiana.* Quite hardy.

48. **Lortétii,** Barbey. Lvs. less than 1 ft. long: st. about 1 ft. high, bearing 2 reduced lvs.: spathe-valves 5 in. long, green or slightly scarious above: outer segms. obovate, much reflexed, 3 in. broad, whitish, finely veined and spotted with red-brown, with a dark spot at the throat; inner segms. orbicular, connivent, pale gray, with red-brown veins. Lebanon. B.M. 7251. Gn. 43:130; 48, p. 337. Gt. 42, p. 490. G.C. III. 12: 153. G.M. 36:386; 40:250. R.H. 1902, p. 404. R.B. 32: 173.—Quite hardy N.

49. **atrofúsca,** Baker (*I. atropurpùrea* var. *atrofúsca,* Baker. *I. Hàynei,* Mallett). Lvs. pale green, 1 ft. long: st. 1 ft. long, hidden by the sheathing inner lvs.: limb dark purple-brown; outer segms. obovate, 3 in. long, with a dark spot on the throat; inner segms. larger and broader; style-branches very convex; crests large. Palestine. B.M. 7379. Gn. 48, p. 8; 50:332 and p. 333. Gt. 42, p. 488; suppl. pl. Gn. W. 24:399. J.H. III. 48:361. G.M. 47:258.

50. **susiàna,** Linn. Mourning Iris. Fig. 1969. Lvs. very glaucous, 6–9 in. long, nearly 1 in. broad: outer segms. obovate, 3 in. long, brownish purple, veined and spotted with black-brown, with a brown beard; inner segms. brownish white, spotted with violet-brown and black. Asia Minor and Persia. B.M. 91. F.S. 11:1087, 1088. R.H. 1859, pp. 322, 323. Gn. 32, p. 193; 39:340; 66, p. 173(?). G. 1:136, 264; 33:203. G.C. III. 51:20. Gn.M. 10:120. Gn.W. 23:426, suppl. A.F. 16:1375.—The best known of



LIX. Japanese irises.—Iris lævigata.

this group. Said to have been intro. from Constantinople in 1753. Name from a city in Persia. Not entirely hardy N., but a good pot-plant. Var. **màjor,** Hort. Bluish, tinted brown.

51. **Bismarckiàna,** Damman (*I. nazarèna,* Hort. *I. Sàri* var. *nazarèna,* Foster). Habit of *I. susiana,* and fls. as large: lvs. 8 in. long: st. 12–18 in. high: outer segms. orbicular, yellowish, densely spotted with purple-brown, with a dark purple-brown spot at the end of the beard; inner segms. orbicular, short-clawed, sky-blue from numerous blue veins on a creamy white ground. N. Palestine. B.M. 6960 (as *I. Sari* var. *lurida*); 7986. R.H. 1902, p. 405. J.H. III. 56, p. 497 (as *I. Sari* var. *nazarensis*). I.H. 42, p. 78(?). Gt. 42, p. 487; suppl. pl. G.M. 40:250.

SUBGENUS PARDANTHOPSIS.

52. **dichótoma,** Pall. Rhizome slender: lvs. 6–8 in a fan-shaped cluster, 8–12 in. long, 1½ in. wide: st. 2 ft. high, much branched, bearing 6–10 heads: spathes not over ½in. long, scarious, 3–5-fld.: fls. fugitive, opening only in the afternoon, twisting spirally when withering; outer segms. with a subquadrate blade contracted into a broadly cuneate claw, whitish, spotted with lilac-purple; inner segms. spreading, oblong-unguiculate, whitish and light purple. August. Irkutsk and Transbaikalia to Manchuria and China. B.M. 6428. B.R. 246.—Although the fls. last only a few hours, they are produced in great profusion so that usually 4–6 are open at the same time.

SUBGENUS APOGON.

A. *Lvs. linear, generally less than ½in. broad.*
B. *Lf.-sheaths splitting into fibers.*
C. *Spathe-valves green.*
D. *Tube of the perianth evident, usually more than ½in. long.*
E. *St. with 1–2 long lvs. immediately below the spathe*....53. **humilis**
EE. *St. bearing a reduced lf. and springing from a pair of reduced lvs. at the base*.....54. **ruthenica**
EEE. *St. sheathed by 1–2 narrow reduced lvs*...............55. **macrosiphon**
DD. *Tube of the perianth short or obsolete, usually less than ½in. long.*
E. *Fls. yellow.*
F. *St. wiry, with a single sheathing lf. low down*.....56. **Hartwegii**
FF. *St. slender, bearing 2 lanceolate sheathing lvs*....57. **Grant-Duffii**
FFF. *St. hollow, bearing a much-reduced lf. near the middle*...................58. **Wilsonii**
EE. *Fls. some shade of blue or white.*
F. *St.-lvs. long, usually over 1 ft. and exceeding the st*..59. **graminea**

53. **hùmilis,** M. Bieb. (*I. ruthénica,* Ker ex parte). Rhizome wide-creeping: lvs. linear, up to 12 in a tuft, glaucous, 6–12 in. long: st. not more than 1–1½ in. long, bearing 2 long lvs. immediately below the spathe: spathe 1-fld.; outer segms. with a suborbicular blade and a long cuneate claw, deep blue-purple with deeper veins, whitish on the throat, with deep purple veins; inner segms. oblanceolate, unguiculate, blue-purple. Caucasus to Georgia and Hungary. Gn. 10, p. 379. —Distinguished from *I. ruthenica* by the 2 long lvs. which arise below the spathe and are 2–3 times as long as the latter.

54. **ruthénica,** Ker. Lvs. linear, in crowded tufts, 6 in. long at flowering-time, becoming 12 in. long: st. slender, 1–8 in. long, but often obsolete; 1-headed: pedicel ¼–2 in. long: tube twice as long as the ovary; outer segms. with an oblong blade rather shorter than the claw, lilac, veined and dotted with bluish purple on a whitish ground near the center and lower part of the blade; inner segms. lanceolate, with narrow claws, deep purple-violet. April, May. China, Siberia and Cent. Asia. B.M. 1123, 1393. Gn. 50, p. 187. G.W. 15:132.—Violet-scented.

55. **macrosìphon.** Torr. Plants rather dwarf, 6–12 in. high: lvs. grass-like, green, 12 in. long, exceeding the fls.: st. 3–6 in. long: pedicels very short: tube 1½–3 in. long; outer segms. obovate-cuneate, undulate, pale yellow to cream, with a network of brownish crimson or bright lilac veins; inner segms. rather small, colored like the outer. Free-flowering. Calif. and Ore. Gn. 52, p. 126. —Torrey says the fls. are bright lilac and the lvs. less than 4 lines wide. The color varies from white to cream-yellow and purple.

56. **Hártwegii,** Baker. Lvs. few (2), 6–12 in. long, finely veined: st. 6 in. long, with a linear lf. low down: pedicel 1–1½ in. long: limb pale yellow; outer segms. with an oblong blade, shorter than the claw. Calif. —Rarely cult.

57. **Grant-Dúffii,** Baker (*I. Áschersonii,* Foster). Lvs. about 1 ft. long: st. 6 in. high, with about 2 lvs., 1-headed: outer segms. with a yellow blade, much shorter than the claw; claw veined with lilac on a yellowish white ground. Palestine. B. M. 7604. Gn. 61, p. 288. Gt. 42; suppl. pl.—Not valuable commercially.

58. **Wílsonii,** Wright. Plants tall, growing in clumps like *I. sibirica* and throwing up clusters of fl.-sts.: lvs. linear-ensiform, 2 ft. long and ½in. broad, slightly glaucous, drooping above: st. about as long as the lvs., 2- or 1-fld., bearing a small lf. at the middle: spathes somewhat herbaceous, 2½–4 in. long: pedicels triangular, 1–5 in. long: outer segms. 2 in. long, ¾in. wide, oblong or obovate-elliptic, pale yellow, veined and dotted with purple on the throat, and on the broad claw; inner segms. oblong-lanceolate, narrowed to a slender claw, pale yellow, mottled with reddish brown at the edges. W. China.—A tall yellow form suitable for cult. with the blue and the white forms of *I. sibirica.*

59. **gramínea,** Linn. (*I. nikiténsis,* Lange). Lvs. linear, 15–36 in. long, strongly ribbed: st. compressed, angled, slender, solid: pedicel 1–1½ in. long: limb bright lilac, copiously veined; outer segms. with an orbicular blade ½in. broad and shorter than the broad claw; claw dull yellow, veined with purple; inner segms. erect, nearly straight. May. Cent. and S. Eu. B.M. 681.—Long cult.; mentioned by Lobel, Clusius and Gerarde. Distinguished from *I. sibirica* by its solid, angular st.

1970. Iris unguicularis. Type of smooth-petaled iris (×⅓). No. 67

60. **tènax,** Douglas. Sheaths short: lvs. 6–12 in. long: st. 6–12 in. long: pedicel ½–2 in. long: outer segm. broadly obovate, with an acute point; blade about as long as the claw, bright lilac, with purple veins and a variegated white and yellow spot on the throat; inner segms. shorter, waved. April, May. Dry soils, Brit. Col. and Ore. Intro. to England 1826. B.M. 3343. B.R. 1218. Gn. 53:518. G.M. 50:867.—Hardy.

61. **ensàta,** Thunb. (*I. gramínea,* Thunb. *I. biglùmis,* Vahl. *I. hæmatophýlla,* Link. *I. Pállasii,* Fisch. *I. longispàtha,* Fisch. *I. oxypétala,* C. A. Mey. *I. fràgrans,* Lindl.). Sheaths large: lvs. 1–3 ft. long: st. 2–12 in. long, flattened, bearing a single terminal head: pedicel 2–4 in., often longer than the spathe: limb loose, bright blue or lilac; outer segms. oblanceolate, 2 in. long; blade shorter than the claw, veined with dark blue, yellowish on the throat; inner segms. slender, erect, bright blue. Russia, Japan, Caucasus. B. M. 2331, 2528. B.R. 26:1. Gt. 1011.—Hardy. Variable. Var. **pabulària,** Naudin (*I. pabulària,* Hort.). Said to be distinct. Larger, with lvs. purplish red near the base. Used as a forage plant. Does well in driest situations. Gt. 47:1452. Described by Wittmack, Gt. 47, p. 369. The seeds should be sown in beds, and the young plants set out the following spring, 10 in. apart each way, where they are to remain.

62. **longipétala,** Herb. Lvs. 1–1½ ft. long, narrow, ensiform: st. stout, solid, compressed, 1½ ft. high: fls. bright lilac; outer segms. obovate, reflexing half way down; claw veined with violet on a white ground. Calif. B.M. 5298.

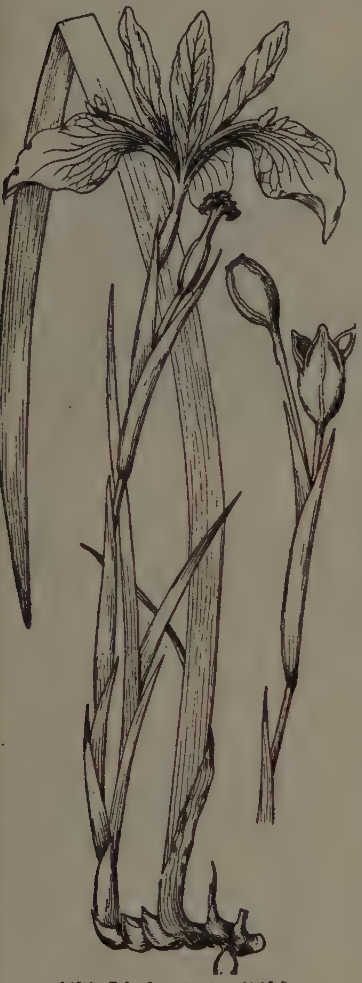
63. **Delavàyi,** Mich. Lvs. 2–2½ ft. long, often nearly 1 in. broad: st. 3–5 ft. high, bifurcate: spathe-valves green: outer segms. reflexed from the middle, oblong, obtuse or emarginate, brilliant violet, spotted with white on the lower half; claw yellow, veined with lilac; inner segms. oblong-lanceolate, acute, erect, violet. Thibet. B.M. 7661. R.H. 1895, p. 399. —Large plants, with the fl.-stalks erect, high above the lvs.

64. **sanguínea,** Donn (*I. orientàlis,* Thunb. *I. sibírica* var. *sanguínea,* Ker. *I. nertschínskia,* Lodd. *I. hæmatophýlla,* Fisch. *I. sibírica* var. *orientàlis,* Baker). Lvs. linear, glaucous, often tinged with red-purple at base, 18 in. long and ⅓–½in. broad: st. about as long as the lvs., bearing a terminal head of 2–3 fls. and rarely a lateral head: spathes slightly scarious at flowering-time, often reddish purple: outer segms. with a suborbicular blade, narrowed abruptly to a short claw, bright lilac, yellowish white at the throat, veined with purple; inner segms. broadly oval, connivent, darker blue. Manchuria. Korea, and Japan. B.M. 1604. L.B.C. 19: 1843.—Often regarded as a variety of the Cent. European *I. sibirica,* which has short subglobose caps. and fls. raised high above the lvs., while *I. sanguinea* has longer trigonal caps. with fls. borne among the lvs.

65. **sibírica,** Linn. (*I. acùta,* Willd.). Compact, tufted: lvs. green, not rigid, 1–2 ft. long: st. slender, terete, fistulose, much overtopping the lvs., simple or forked, bearing several clusters of fls.: spathe small, narrow, acute, entirely scarious at flowering-time: limb bright lilac-blue; outer segms. 1½–2 in. long, with an orbicular blade gradually narrowed to a slender claw, veined with bright violet, whitish toward the claw; inner segms. shorter, erect. Cent. and S. Eu. and E. Siberia. Intro. in 1796. B.M. 50. R.H. 1898,

p. 23. G.W. 12:678. Gn.M. 15:362.—Common in cult. The plants form large, compact clumps, producing many long flowering sts. from the center. Each st. usually has a terminal cluster of 2–5 fls. and 1 lateral head. Var. **variegàta,** Hort., has variegated lvs. Var. **acùta,** Hort. Narrow-lvd. Var. **flexuòsa,** Murray (*I. flexuòsa,* Murray. *I. sibírica* var. *álba,* Hort.). Fls. white with crisped segms. B.M. 1163.

66. **prismática,** Pursh (*I. grácilis,* Bigel. *I. virgínica,* Muhl.). Plant tall, slender: lvs. mostly shorter than the st., grass-like: st. 1–2 ft., simple or forked, flexuous: spathes 1–2-fld.: pedicel long, exceeding the spathe: outer segms. 1½–2 in. long; blade shorter than the claw, bright lilac, yellow on the throat, marked with purple and darker veins; inner segms. erect, bright lilac. May, June. Wet grounds, New Bruns. to Pa. and N. C. B.M. 1504.



1971. Iris bracteata. (×½)

67. **unguiculàris,** Poir. (*I. stylòsa,* Desf. *I. creténsis,* Janka). Fig. 1970. Lvs. about 6 in a tuft, finally 1½–2 ft. long, bright green: st. nearly obsolete: spathes 2–3-fld.; valves 4–6 in. long, scarious at the tip only, shorter than the tube: tube 5–6 in. long, filiform, exserted from the spathe; limb bright lilac, rarely white; outer segms. 2½–3 in. long, 1 in. broad, with a yellow keel, streaked with lilac on a white ground at the throat; inner segms. oblong. Jan., Feb. Algeria, Greece and Islands, Asia Minor and N. Smyrna. B.M. 5773; 6343. R.H. 1900:300. Gn. 24:68; 46:248; 49, p. 236; 50, p. 187. G.C. III. 25:85. F.S.R. 35, p. 131. G. 9:590; 34:115. G.L. 19:48; 22:378. Gn. W. 20:159.—Not hardy, but useful for cutting in early winter. Fragrant. Var. **álba,** Hort. White form; spring. C.L.A. 5:134. Gn. 68, p. 381. Var. **supérba,** Hort. Bluish purple. Oct. and later. Var. **speciòsa,** Hort. Fls. well above the foliage, deep reddish purple.

68. **bracteàta,** Wats. Fig. 1971. Rudimentary lvs. brown, very rigid; produced lvs. 1 to few, much exceeding the st., 1–2 ft. long, one side green, the other glaucous, edge revolute: st. 1-headed, angled, 2–3 in. to 1 ft. long, sheathed with bracts 2–4 in. long: tube short, funnelform; outer segms. 2–3 in.; blade ovate, as long as the claw, pale yellow, veined with bluish purple; inner segms. shorter, erect, yellow; style-branches long, narrow. June. Discovered in 1884 by Thomas Howell, in Ore. G.F. 1:43 (adapted in Fig. 1971). G.C. III. 39:401; 52:328. G.M. 50:161.—Intro. 1888.

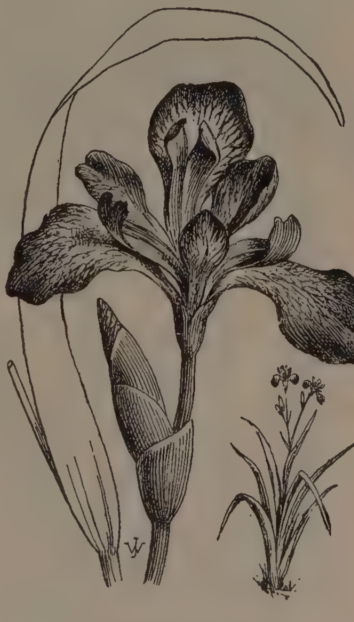
69. **Síntenisii,** Janka (*I. gramínea* var. *Síntenisii,* Richter. *I. Urúmovi,* Velenovski). Lvs. narrow, linear, acuminate, 8–18 in. long, ¼–½in. broad: st. round, not flattened as in *I. graminea,* slender and flexuous, 4–12 in. long, almost entirely clothed by 2–3 reduced lvs. and bearing a single head of 2 fls.: spathe-valves narrow, linear, acuminate, keeled, the inner longer than the outer: ovary tapering to a long neck taking the place of the perianth-tube: fls. bright lilac, 1½ in. long; outer segms. with an obovate blade and a slightly pandurate claw, bluish purple, whitish toward the throat, marked with purple veins and with reddish purple veins on the claw; inner segms. oblanceolate with a cuneate claw deep blue-purple; style-crests lanceolate. S. Italy, Balkan Peninsula, Asia Minor and Turkey.

70. **Douglasiàna,** Herb. Rhizome stout, short, creeping: lvs. about 6 in a tuft, broadest in the middle, strongly ribbed, 1–2 ft. long: st. 1–2 ft. high, usually simple, with 1 long bract-lf.: tube ½–¾in. long: fls. 3–4 in. diam.; outer segms. obovate-spatulate, spreading and recurved, pale lilac, with a white disk and purple veins; inner segms. shorter, erect, lanceolate, acuminate, pale lilac, veined. Calif. B.M. 6083. Gn. 50: 272.—Exists in an endless variety of color-forms, varying from pale lilac to deep violet with considerable variation in the veining.

71. **missouriénsis,** Nutt. (*I. Tolmieàna,* Herb.). Lvs. pale green, finely ribbed, 1–1½ ft. long: st. 1–2 ft. long, usually exceeding the lvs., bearing a single large lf. low down: pedicel long: tube very short; limb bright lilac; outer segms. obovate, 1 in. broad, yellow near the claw; inner segms. oblong, emarginate, straight, erect. Wet soil. S. D. and Mont. to Ariz. B.M. 6579. Gn. 50:186.—Not common in cult. Flowers early.

72. **fúlva,** Ker (*I. cùprea,* Pursh). Lvs. thin, bright green, 1½–2 ft. long, not exceeding the st.: st. 2–3 ft. high, forked low down; lower st.-lvs. 1 ft. long: pedicel produced: tube greenish yellow, 1 in. long; limb loosely expanded, bright reddish brown or copper-colored, variegated with blue and green; outer segms. obovate-cuneate, emarginate; inner segms. smaller, spreading. Late June. In swamps, Ill. to Ga., La. and Texas. Intro. into England 1811 by Lyon. B.M. 1496. Gn. 53:518. Mn. 5:61.

73. **Pseudácorus,** Linn. (*I. acoroìdes,* Spach. *I. flàva,* Tornab.). Lvs. 1½–3 ft. long, equaling the st.: st. stout, terete, 2–3 ft., bearing several long lvs. and several clusters of fls.: limb bright yellow; outer segms. broadly obovate, 2–2½ in. long, yellow, with a bright spot and radiating brown veins on the claw; inner segms. scarcely longer than the claw of the outer, oblong. May, June. Eu., Syria and the Barbary states; naturalized in N. Y., Mass. and N. J.—The plants



1972. Iris versicolor (×½). No. 74

form fine, large clumps, bearing numerous flowering stalks. Var. **variegàta,** Hort. Lvs. striped with creamy white. Var. **pállida,** Hort. Fls. pale sulfur-yellow.

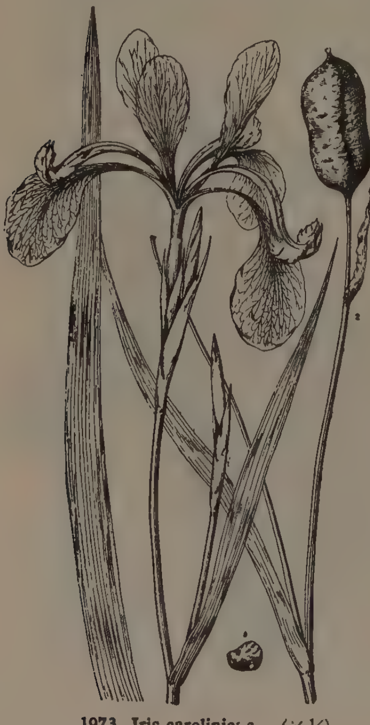
74. **versícolor,** Linn. (*I. virgínica,* Linn.). Fig. 1972. Lvs. slightly glaucous, 1½–2 ft. long: st. forked low down and often branched above, 2–3-headed: tube very short; limb violet-blue; outer segms. spatulate, 2–3 in. long, variegated with yellow on the claw and veined with purple; inner segms. oblanceolate, much smaller. British N. Amer. and N. U. S. Intro. into England 1732. B.M. 21, 703.

75. **hexagòna,** Walt. Lvs. 2–3 ft. long: st. usually simple, 3 ft. long, 2–3-headed, with several large lvs., the upper ones exceeding the fls.: spathe-valves sometimes lf.-like: tube 1 in. long, green, dilated upward; limb bright lilac; outer segms. 3 in. long; blade obovate, with a bright yellow keel on the claw; claw downy; inner segms. shorter, erect; style-branches very concave, green, with a central lilac band. Ky. to Texas. and Fla. B.M. 6787.

76. **caroliniàna,** Wats. Fig. 1973. Lvs. 2–3 ft. long, bright green: st. stout, simple or branched: tube ½in. long; limb lilac, variegated with purple and brown; outer segms. broadly spatulate, 2½–3 in. long, with narrow claws; inner segms. narrower, nearly erect. Differs from *I. versicolor* by its green lvs. Discovered by W. A. Manda in N. C. B.M. 8465. G.F. 6:335 (adapted in Fig. 1973).

77. **setòsa,** Pall. (*I. brachycúspis,* Fisch. *I. tripétala,* Hook.). Lvs. thin, green, 1–1½ ft. long: st. deeply forked, much exceeding the lvs.: tube ¼in. long; limb bright lilac; outer segms. 2–2½ in. long; blade 1 in. broad, suddenly narrowed at the claw, copiously veined; inner segms. very small, ½in., cuneate, large-cuspidate; style-branches large, crested. E. Siberia, Japan, and N. W. Amer. to Labrador and Maine. B.M. 2326; 2886. Gt. 322.

78. **Monnièri,** DC. Lvs. slightly glaucous, 2–3 ft. long: st. stout, terete, 3–4 ft. long, with several sessile clusters of fls.: limb 2½–3½ in. long, lemon-yellow, without veins; blade of outer segms. orbicular, 1–1½ in. long, equaling the claw; inner segms. oblong-unguiculate, 1 in. broad. Origin not certainly known. Found in the garden of Lemonnier at Versailles. G. 25:389.—Not showy except in masses. This and *I. orientalis* and *I. aurea* are very closely related and together with *I. halophila* are perhaps all forms of *I. spuria. I. Monnieri* is uniformly bright lemon-yellow, free from veins or spots. By its coloring, it differs from *I. orientalis* and by the orbicular blade of the outer segms. from *I. aurea,* in which the blades are oblong. Often attributed to Crete.



1973. Iris caroliniana. (×½)

79. **halóphila,** Pall. (*I. Gueldenstædtiàna,* Lepech.). Lvs. pale green, 1–1½ ft. long: st. stout, terete, 1½–2 ft. long, often bearing 1–2 spicate clusters below the end one: limb pale yellow; outer segms. with an orbicular blade ½–¾in. broad, shorter than the claw, which has a bright yellow keel and faint lilac veins, inner segms. shorter, erect. Asia. B.M. 1515 (*I. spuria* var. *stenogyna,* Ker).

80. **orientàlis,** Mill. (*I. ochroleùca,* Linn. *I. gigantèa,* Carr.). Fig. 1974. Plants growing in strong clumps: lvs. 2–3 ft. long, 1 in. or more broad, slightly glaucous: st. 3 ft., stout, terete, about as long as the lvs., with 2–3 spicate clusters of fls.: outer segms. obovate, 1 in. broad, as long as the claw, yellow, paler or white toward the margin; inner segms. oblong, 1 in. broad, lemon-yellow to whitish. Asia Minor and Syria. B.M. 61. Gn. 20:272; 38:462; 46, p. 362; 50, p. 186; 69, p. 25; 72, p. 622. Gn. M. 15:360. R.H. 1875, p. 357.—One of the largest of the irises. Grows in almost any situation. White forms of this plant are in cult. but no purple forms are known. See note under *I. Monnieri.*

1974. Habit sketch of Iris orientalis. (×$\frac{1}{20}$)

81. **aùrea,** Lindl. Lvs. scarcely glaucous, 1½–2 ft. long: st. 3–3½ ft. long, stout, terete, with 1–2 sessile lateral clusters below the end one: spathes 2–3-fld.: pedicel long: limb bright yellow; outer segms. with an oblong undulate blade 1 in. broad, as long as the claw; inner segms. less than ½in. broad, with much-waved edges. July. W. Himalayas. B.R. 33:59. Gn. 31:52. G. 25:388. B.M. 1131 (as *I. spuria* var. *halophila*).—Intro. by Dr. Royle. The color is a rich golden yellow, much deeper than that of *I. Monnieri* and the others of this group. See *I. Monnieri.* Said to grow up to 5 ft. high under favorable conditions. Var. **intermèdia,** W. I., in G.C. III. 28:22. Intermediate between *I. aurea* and *I. orientalis.* Deep yellow, with crisped segms. like *I. aurea,* but having the obovate outer segms. and narrow inner segms. of *I. orientalis.* Fls. late, with *I. aurea.*

82. **fœtidíssima,** Linn. GLADWIN. Lvs. 1–1½ ft. long: st. compressed, 2–3 ft. long, 2–3-headed: tube ½in long; limb bright lilac; outer segms. 1½–2 in. long, with a suborbicular blade equaling the claw; inner segms. shorter, oblanceolate. Cent. and S. Eu., England, Afghanistan and Algeria. Gn. 47, p. 30. G. 19:543.—This plant is very distinct, and is easily recognized by the odor of the broken lvs. The caps. remain on the plants in winter, bursting open and displaying rows of orange-red berries. The fls. are rather inconspicuous. There is a whitish variety with brown veins, and a variety with white-striped lvs. A pale yellow form veined with green also occurs occasionally.

83. **spùria,** Linn. Lvs. firm, linear, glaucescent, 1 ft. long, longer after flowering: st. overtopping the lvs., bearing 1–3 spicate heads: pedicel shorter than the spathe: tube ½–¾in. long; limb bright lilac; outer segms. with an orbicular, spreading blade ½in. broad and half as long as the claw; claws broad, concave, lilac, with a yellow keel and purple veins; inner segms. shorter, straight, oblanceolate; style-crests small. Cent. and S. Eu. B.M. 58. Var. **nòtha,** Bieb. (*I. halóphila,* Ker). More robust: lvs. 1 in. broad: spathes larger:

st. 2–3 ft. high. Caucasus to Kashmir. B.M. 875.—Hardy. Var. **desertòrum,** Ker. Fls. pale lilac; claws of the segms. yellow. B.M. 1514. Var. **sogdiàna,** Bunge (*I. sogdiàna,* Bunge). A variety with gray-lilac fls.

84. **lævigàta,** Fisch. (*I. Kaémpferi,* Sieb. *I. álbopurpurea,* Baker). Japanese Iris. Figs. 1975, 1976. Lvs. thin, ensiform, 1–1½ ft. long: st. much overtopping the lvs., obscurely angled, 1–3-headed: pedicel ½–2 in. long: tube short; limb blue, violet, etc., sometimes white, spreading, 3–5 in. across; outer segms. broadly ovate-oblong, obtuse; with a yellow spot on the claw; claw short, distinct; inner segms. oblanceolate, erect, conniving or spreading; style-branches with bifid, incurved lobes. E. Siberia and Japan. Intro. by Von Siebold, and flowered at Ghent in 1857. B.M. 6132; 7511. I.H. 5:157. F.S. 20:2073, 2074; 23:2431–6. Gt. 442; 29:1003. Gn. 9:476; 16:198; 21:424; 55, p. 105; 60, p. 349; 74, pp. 336, 363, 365; 75:226. R.H. 1890, p. 188. G.C. II. 2:47; III. 13:165, 169; 14:501; 44:141. A.G. 19:596. Gng. 1:256; 5:163; 6:339; 7:145. J.H. III. 28:205. F.E. 10:777. F.M. 1874:137; 1880:403. G.W. 2:66; 12:220 (var. *alba*). Gn.M. 5:343; 15:361. C.L.A. 3:179. G. 19:195. R.B. 36:245 (as *I. japonica*). G.F. 1:259 (adapted in Fig. 1975).—On account of the presence of a prominent ridge, formed by one or more veins along the middle of the lvs. of *I. Kaempferi,* this species is sometimes considered as distinct from *I. lævigata.* If the species are distinct, the numerous cult. forms of Japanese irises are probably all derived from *I. Kaempferi* since, at least so far as available material from forms cult. in the U. S. shows, all have the prominent midrib on the lvs.

1975. Japanese iris.—I. lævigata.

85. **vérna,** Linn. Dwarf, 6 in. high: rhizome wide-creeping: sheaths not splitting into fibers: lvs. linear, slightly glaucous, 3–8 in. long: st. scarcely any, 1-headed: tube slender, 1½ in. long; limb deep violet; outer segms. 1½ in. long, obovate, narrowed into a slender yellow, slightly pubescent claw; inner segms. erect, smaller, violet. Shade, Ohio, Ky., Va. and south. L.B.C. 19:1855. B.M. 8159.—An anomalous species with the habit of a pogoniris but lacking the beard.

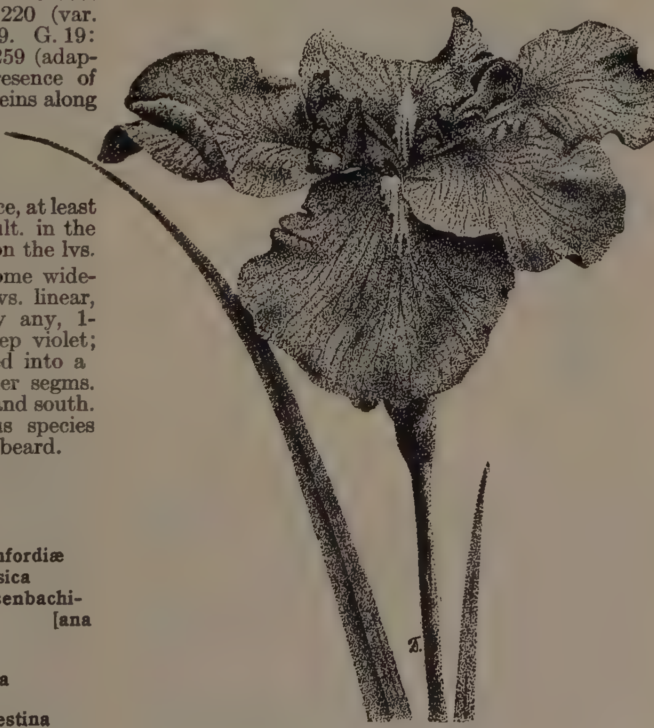
86. **Dánfordiæ,** Boiss. (*I. Bórnmuelleri,* Hausskn.). Fl.-sts. 2–4 in. high: lvs. very short at flowering time finally a foot long: fls. bright yellow, 1½ in. diam.; outer segms. with an orbicular blade spotted with brown; claw cuneate; inner segms. reduced to minute, spreading, subulate teeth; style-crests large. Spring. Cilician Taurus. B. M. 7140. Gt. 39:1327. Gn. 37:462; 67, p. 89. G.C. III. 27:170.—Fragrant.

87. **pérsica,** Linn. Bulb ovoid: lvs. 4–5, 2–3 in. long, becoming 6 in. long after flowering time, with white obscurely ciliated edges: st. short, 1-headed: tube 2–3 in. long; limb pale lilac; outer segms. with an orbicular blade with a dark purple blotch, an orange keel, and purple lines and spots; claw auriculate; inner segms. small. Asia Minor and Persia. B.M. 1. Gn. 11, p. 207; 14:490; 33:558; 54, pp. 103, 470; 66:8. F.S. 10:1045. G.C. III. 7:577. R.H. 1912, p. 454.—Should



1976. Japanese iris.—Iris lævigata, better known as Iris Kaempferi. (×½) be lifted in summer. Var. **purpùrea,** Dykes (*I. purpùrea,* Siehe). A bright purple variety. Fine. Var. **Sieheàna,** Dykes (*I. Sieheàna,* Lynch. *I. Haussknéchtii,* Siehe). Similar to var. *purpurea,* but with larger, silvery gray fls. marked with reddish purple. B.M. 8059. G.C. III. 35:251. Var. **stenophýlla,** Dykes (*I. stenophýlla* Hausskn. & Siehe. *I. Heldreìchii,* Hort.). Fls. pale blue; outer segms. blackish blue at the tip, with spots of the same shade on the rest of the blade; keel yellow; crests of the style-branches nearly as large as the outer segms., suborbicular, crenate. Cilician Taurus. B.M. 7734. G.C. III. 27:171. Gn. 59, p. 225; 76, p. 132. F.S.R. 2:328. Var. **Taùri,** Dykes (*I. Taùri,* Siehe). Fls. bright violet-purple veined with white on the lower part of the blade and on the claw of the outer segms.; keel deep orange; inner segms. depressed, 3-lobed. B.M. 7793. G.C. III. 29:191. Gn. 61, p. 93.

88. **Rosenbachiàna,** Regel. Lvs. 4–5, finally 6–8 in. long and 2 in. broad: st. short, 1–3-headed: outer segms. obovate-cuneate; blade reflexed, white at the tip, deep purple in the middle and creamy below, with a yellow keel and dark lilac veins; inner segms. spreading or reflexed, obovate, pale lilac. The color of the fls. is very variable. Mountains of Turkestan. B.M. 7135. Gt. 35:1227. Gn. 33:558 J.H. III. 28:189. G.C. III. 7:577. G.M. 34:171. C.L.A. 5:134; 9:410.

1977. Iris orchioides.—A good species for pots or the open. (×¼)

89. **alàta,** Poir. (*I. scorpioìdes,* Desf. *Xìphium planifòlium,* Mill.). Lvs. about 6, plane, 6–9 in. long: st. very short, 1–3-fld.: tube 4–6 in. long; outer segms. 3–4 in. long, obovate-cuneate, bright lilac, variegated with white, and having a yellow keel down the claw; inner segms. obovate-unguiculate, spreading from the base of the outer; style-crest large, laciniately toothed. Spain to Sicily and Algeria. B.M. 6352. B.R. 1876. Gt. 40:1351 (vars.). Gn. 10, p. 579; 54, p. 102. G.C. III. 45:52. G.M. 35:614. G. 1:665; 11:689; 35:55. Gn.W. 20:185.—Winter-flowering. Plants very dwarf.

90. **palæstìna,** Boiss. Lvs. 3–6 in. long: st. very short, 1–3-fld.: tube 2–3 in. long: fls. pale yellow, tinged with lilac; outer segms. oblong, upper one-fourth reflexed; claw auriculate; inner segms. minute, narrowly lanceolate. Mountains of Palestine.—Fls. in winter. Very near *I. caucasica,* but distinguished by its longer acuminate spathes and the color of the fls.

91. **Willmottiàna,** Foster. Lvs. about 8, with a white horny edge, broad, not acutely channelled, deep glistening green: st. 6–8 in. high, 4–6-fld.: fls. sessile, lavender or pale purple; tube 2 in. long; outer segms. oblong, with a white patch at the throat, marked with veins and patches of deeper purple, claw with white and purple markings; outer segms. small, depressed, cuspidate; style-crests small, triangular. Mountains of E. Turkestan. Gn. 59, p. 411; 75, p. 128; 66:8. G.C. 47:364; III. 29:271.—Resembles *I. caucasica* in habit and size but has narrower spathe-valves which are not inflated.

92. **caucásica,** Hoffm. Lvs. about 6: st. very short, 1–4-fld.: fls. pale or bright yellow; outer segms. with an ovate blade and a very broad rhomboidal claw, with small auricles and a toothed or ciliated crest; inner segms. oblanceolate. Caucasus to Asia Minor, etc. Gt. 1874:800. C.L.A. 9:409.—Dwarfer habit than *I. orchioides.*

93. **Fosteriàna,** Aitch. & Baker. Lvs. 8–10 in. long: st. 6–8 in. long, 9–12 in. long after flowering, hidden by the clasping lvs., 1–2-fld.: outer segms. yellow, streaked with black, obovate-cuneate; claw not auriculate; inner segms. shorter, obovate, bright purple. March. Afghan and Russian boundary. B.M. 7215.—Very different from the allied species *I. orchioides* and *I. sindjarensis,* and so on, on account of the difference in color of the sepals and petals.

94. **cærùlea,** Fedtsch. (*I. caucásica* var. *cærùlea,* Regel. *I. orchioìdes* var. *cærùlea,* Hort.). Lvs. about 8: st. about 15 in. high, bearing 3–4 fls. in the axils of the lvs.: fls. bright lilac; outer segms. with a ligulate claw expanded slightly at the base and an obovate-oblong blade with a conspicuous whitish crest and a yellow blotch on the throat; inner segms. pendent, with a narrow pointed lanceolate blade. Turkestan.

95. **warleyénsis,** Foster. Lvs. 6–7, 6 in. long, 1–1½ in. broad, with a conspicuous horny margin: st. 1 ft., 3–5-fld.: fls. sessile; outer segms. with a strap-shaped claw expanding into an orbicular blade, deep violet with a whitish crest and an orange patch at the throat, claw pale violet with deeper markings; inner segms. narrow, pale blue, purple, or violet, cuspidate. Turkestan. B.M. 7956. Gn. 61, p. 241; 72, p. 635. G.C. III. 31:386. J.H. III. 44:339. F.S.R. 3:344. G.M. 46:322.

96. **sindjarénsis,** Boiss. Lvs. about 8, crowded, distichous, glossy above, conspicuously striated below, 8–10 in. long, 1½–2 in. broad: st. 6–9 in. long, 3–6-fld.: fls. slaty lilac; outer segms. with an obovate, reflexed blade narrowed to a claw, with darker lilac lines and a small yellow crest; inner segms. oblong, clawed. Feb. Deserts of Mesopotamia. B.M. 7145. G.C. III. 7:365. J.H. III. 28:227; 48:97. Gn. 69, p. 134. Gn.W. 21:260; suppl. pl.—Plants ½ft. high. Var. **assyrìaca,** Lynch (*I. assyrìaca,* Hort. or Hausskn.), is a white variety from Mesopotamia. Gn. 69, p. 195. C.L.A. 9:409.

97. **fumòsa,** Boiss. & Hausskn. Lvs. about 10: st. 6 in. long: outer segms. spatulate-oblanceolate, recurved above the middle, claw with a yellow crest; inner segms. minute, spatulate, toothed. The fls. are greenish yellow, shaded with smoky gray. Dry fields, Syria.—Perhaps a variety of *I. sindjarènsis.*

98. **orchioìdes,** Carr. (*I. caucásica,* Regel). Fig. 1977. Lvs. about 6: st. 12–15 in. long, with distinct internodes: spathes 1-fld., 2 in. long: fls. yellow; outer segms. with an obovate blade, and a purple blotch on each side of the crest of the claw; inner segms. oblanceolate, less than an inch long, and generally sharply deflexed, with a long filiform claw. B.M. 7111. Gn. 53, p. 482. R.H. 1880, p. 337. Spring. Var. **oculàta,** Maxim. Blade of the outer segms. more spotted.

SUBGENUS XIPHIUM.

99. **Xíphium,** Linn. (*I. hispánica,* Hort. *I. spectábilis,* Spach). SPANISH IRIS. Fig. 1978. Lvs. about 1 ft. long: st. 1–2 ft. high: pedicel long. tube obsolete; outer segms. 2–2½ in. long, violet-purple, yellow in the center; inner segms. as long, but narrower. Late June. Spain and N. Afr. B.M. 686. Gn. 20:442; 30, p. 385; 54, p. 471.—Long cult. and well known. Hardy in N. J. in protected situations. Var. **lusitánica,** Foster (*I. lusitánica,* Ker). Fls. yellow. B.M. 679. Var. **Báttandieri,** Foster. Fls. pure white, except the orange keels of the outer segms. Lvs. very glaucous. Algeria.

100. **xiphioìdes,** Ehrh. (*I. ánglica,* Hort.). ENGLISH IRIS. Lvs. about 1 ft.: st. 1–2 ft.: fls. dark violet-purple in the typical form; outer segms. orbicular, yellow in the center; inner segms. shorter, oblong. French and Spanish Pyrenees. B.M. 687. R.H. 1891:36; 1907, p. 446. Gn. 30, p. 384; 31:212; 54, p. 471. Gn.M. 15:362. G.W. 12:547 and p. 549 (vars.).

101. **júncea,** Poir. (*Xíphium júnceum,* Klatt). St. slender, erect, rigid, 9–18 in. high, bearing 1 (rarely 2) golden yellow fls., 2–3 in. diam.: lvs. rigid, slender, rush-like, 18–24 in. long: outer segms. with an orbicular blade shorter than the cuneate claw, recurved and veined with brown; inner segms. erect, oblanceolate. May, June. Algeria, Tunis, etc. B.M. 5890. Gn. 54:470.

102. **Boissièri,** Henriq. Lvs. linear, very deeply channelled, 1 ft. long: st. about a foot long, bearing few, reduced lanceolate lvs. and a single fl.: outer segms. 1½ in long; blade obovate, reflexed, as long as the cuneate claw, bright lilac, with a yellow keel running down the claw, slightly bearded; inner segms. as long as the outer, erect, obovate, clawed, bright lilac. June. S. Portugal. B.M. 7097.

103. **filifòlia,** Boiss., not Bunge (*Xíphium filifòlium,* Klatt. *X. tingitànum,* Hook.). Slender and leafy, about 2 ft. high, bearing 1–2 bright violet-purple fls. 2–2½ in. diam.: lvs. about 1 ft., those of the non-flowering bulbs twice as long, weak, flexuous, convolute: outer segms. with a narrow claw expanding suddenly into a reflexed, suborbicular blade, bright yellow down the center; inner segms. erect, obovate-lanceolate, erose, notched. S. Spain and N. W. Afr. B.M. 5928; 5981.—Intro. 1869. Hardy.

104. **tingitàna,** Boiss. & Reut. (*I. Xíphium,* Desf.). St. stout, 1–2-headed, about 2 ft. high, hidden by the sheathing bases of the stout, falcate lvs., of which there are 6–7 on the st., the lower about 1 ft. long: fls. 2–3 in a cluster; outer segms. 3 in. long, with an obovate, reflexed blade, pale lilac, yellow in the center, and with a bright yellow keel down the claw; inner segms. shorter, oblanceolate, erect, incurved. Tangiers. B.M. 6775. Gn. 36:294; 63, p. 41; 71, p. 404; 74, p. 349; 75, p. 323. G.C. III. 37:339; 40:24; 48:16, 17. G.M. 40:377. J.H. III. 50:429.

105. **reticulàta,** Bieb. Lvs. 2–4 in a tuft, short, erect quadrangular, with horny edges, elongating to 1½ ft.: st. very short: tube 3–6 in. long; fls. bright purple, very fragrant; outer segms. 2 in. long, yellow at the claw, with a low yellow crest; inner segms. narrower. Mid-April. Asia Minor and Persia. B.M. 5577. F.S. 5, pp. 509. R.H. 1890, p. 133; 1912, p. 454. Gt. 779; 13:452. Gn. 20:112; 54, p. 471; 59, p. 233. G.C. II. 11:501; 21:217; III. 52:339. F. 1860:161. G. 19:466. G.M. 51:695. F.W. 1871:225. Var. **histrioìdes,** Foster (*I. histrioìdes,* Dykes). Outer segms. much mottled with white and lilac on the claw and broad, orbicular blade. Asia Minor, Persia, and the Caucasus. Gn. 42:364; 62, p. 42 and 77, p. 42. G.M. 51, p. 87. J.H. III. 34:111.—Early-flowering, and fine for pots. Var. **Krèlagei,** Regel. Fls. red-purple, varying

1978. Iris Xiphium.—Type of bulbous iris. (×¼) greatly in shade; claw conspicuously veined. The common wild form of the Caucasus. Nearly odorless. L.B.C. 19:1829. Gt. 22:779. R.B. 18:60. G.C. II. 21:217. Var. **cærùlea**, Hort. Azure-blue. Var. **cyànea**, Regel. Blue. Gt. 23:797. Var. **màjor, Hort.** Like the type, but larger. Gn. 60, p. 198.

106. **Hístrio,** Reichb. f. (*Xiphium Histrio,* Hook. f. *I. reticulàta* var. *Histrio,* Foster). Plants tufted, slender and flaccid: lvs. quadrate, with horny edges, deeply grooved on each face, 1 ft. long: st. very short, very slender, 1-fld.: fls. 3 in. diam.; tube 3–4 in. long, blue above; outer segms. obovate-spatulate, spreading, deep blue, with a yellow line in the center bordered with white and spotted and shaded with blue; inner segms. erect, oblanceolate, blue. Feb. Mountains of Palestine. B.M. 6033. Gn. 9, p. 29; 33:558. G.C. III. 12:729; 21:105; 45:55.—Related to *I. reticulata,* differing only in its paler, odorless fls., which are produced several weeks earlier.

107. **Vártanii,** Foster. Lvs. usually 2, 8–9 in. long, slender, finally longer: st. very short, hidden: tube 2½ in. long; outer segms. with a narrow claw, suddenly enlarged into an ovate-lanceolate blade, pale, slaty lilac, with darker veins and a crisp yellow crest down the claw; inner segms. erect, almost linear-lanceolate, pale lilac. Dec. Palestine, near Nazareth. B.M. 6942. Gn. 77, p. 69.—Not scented.

108. **Bakeriàna,** Foster. Lvs. 3–4, 6–9 in. long, finally a foot or more after flowering, hollow, cylindrical, 8-ribbed: fls. single, on a short peduncle, fragrant; tube 3–6 in.; outer segms. with a long, obovate-elliptical claw, and a small, ovate, reflexed blade, intense violet, creamy in the center, with a yellow streak down the claw; inner segms. shorter, erect, oblanceolate, lilac; style-crests large. Feb., March. Armenia. B.M. 7084. Gn. 37:462. G.C. III. 7:293; 21: 103; 45:53. J.H. III. 34:177; 42:142. G.M. 40:118.

109. **Kolpakowskiàna,** Regel (*Xiphium Kolpakowskiànum,* Baker). Lvs. 5–6, wrapped round by a sheath at the base, very short at the flowering time, but growing longer, linear, channelled, with thickened edges: scape very short, 1-fld.; tube 2–3 in. long; outer segms. with a long, erect claw and an ovate, acute blade, deep violet-purple with a yellow keel down the claw; inner segms. oblanceolate, erect, pale lilac. Mountains of Turkestan. B.M. 6489. Gn. 17, p. 75; 33:558. Gt. 1878:939.—Very near *I. reticulata,* fls. at the same time, and is sweet-scented.

SUBGENUS GYNANDRIRIS.

110. **Sisyrínchium,** Linn. (*Moræa Sisyrinchium,* Ker. *Xiphium Sisyrinchium,* Baker. *I. maricoìdes,* Regel). St. 6–12 in. high, stout or flexuous, 1–3-headed: lvs. 2, slender, as long as the st.: fls. fugitive, lilac-purple, with a yellow, oblong spot on the outer segms. which are oblong-spatulate; inner segms. narrow-lanceolate, erect, pale; style-crests large, lance-deltoid. Widely spread through S. Eu., Afr. and Asia. B.M. 1407 (not good), and 6096.—Easily killed by frost. In *I. maricoides,* Regel, the filaments are said to be distinct from each other and from the style.

Of some of the names, found in catalogues, no complete description is available: *I. àmas,* Hort. Germanica group.—*I. angustìna.* Deep yellow, marked with maroon. Garden form of I variegata.—*I. angustíssima,* Hort. Fls. dark purple.—*I. brachysìphon.* Pale blue. Rhizomatous.—*I. británnica.* Pale pink, with the outer segms. veined with purple. Garden form of I. squalens.—*I. Brooksiàna,* Hort. Mauve-purple.—*I. candiàna.* Outer segms. reddish purple; inner segms. light lavender. Germanica.—*I. coreàna.* Like I. sibirica, early and a free bloomer.—*I. edìna.* Light purple and violet. Var. of I. neglecta.—*I. Físheri.* Apogon.—*I. Gladstoniàna.* Hybrid of I. atropurpurea. Pale black, with yellow markings. —*I. grácilis,* Lichten.=Moræa tenuis. See also index, p. 1668.—*I. Guáldii,* Hort.—*I. ignitítia,* probably Ignacite, a form of I. neglecta. Lilac, with the outer segms. shaded purple.—*I. ligulàris.* Purple. Germanica. —*I. macrántha,* Hort. Germanica. —*I. nígricans.* Lvs. short ensiform: fls. dull black to deep black. Distinct from I. atropurpurea by its uniform dark color and dwarf foliage. Oncocyclus.—*I. páncrea,* probably pancrace, var. of I. variegata. Buff and purple.—*I. Robinsoniàna,* F. Muell.=Moræa Robinsoniana.—*I. Rùdinii,* Hort., Herb. Fls. black-brown and claret. Said to be stronger and more free-flowering than the other oncocyclus irises.—*I. tuberòsa,* Linn.=Hermodactylus tuberosus. —*I. Vogeliàna.* Similar to I. persica and I. Rosenbachiana, but earlier-flowering. Fls. variable in color, silver-gray predominating, with violet, rose or lilac markings. Var. *grandiflòra.* Large-flowering.

The following are garden hybrids, sometimes cult.: *I. interrégna* =I. germanica × I. pumila. Several color vars., pale yellow, citron, lavender, and claret-red: fl.-sts. 18 in. high, holding the fls. well above the lvs. —*I. mónspur,* Foster=I. Monnieri × I. spuria. Said to be very ornamental.—*I. ochro-aùrea* or *ochaùrea,* Foster=I. orientalis × I. aurea. Outer segms. rich yellow with a cream-colored border; inner segms. erect, yellowish, bilobed at the apex. 5 ft. —*I. páravar* or *I. párvar,* Foster=I. paradoxa × I. variegata. Sts. 2-fld.: fls. dark purple with the bases of the segms. pale brown with darker markings. G.C. III. 29:398.—*I. síndpers,* Van Tubergen=I. sindjarensis × I. persica. Intermediate between the parents in foliage and general habit. Free-flowering: fls. blue like those of I. sindjarensis but lacking the conspicuous patch at the apex of the outer segms.

The following species are sometimes cult: *I. gracílipes,* Gray. Rootstock slender, wide-creeping: lvs. finally 1 ft. long, ⅓in. broad: st. 8–10 in. high, forked once or twice: spathes of a single, membranous, scarious valve which reaches about the top of the tube, 1-fld.: fls. purple or lilac; outer segms. obovate-cuneate, deeply emarginate, about 1 in. long, white in the middle, veined with purple and bearing a yellow crest; inner segms. oblanceolate emárginate, smaller, uniformly colored. Japan. B.M. 7926.—A small pretty iris of the Evansia group.—*I. Púrdyi,* Eastwood. Rootstock thin and wiry: lvs. 1 ft. long and ⅓–½in. wide. thick, sub-erect: st. 4–6 in. long, entirely covered by the short inflated bracts: spathe-valves 1½–2 in. long, inflated, the outer slightly keeled: fls. pale straw-yellow; tube 1¼–1½ in. long; outer segms broadly lanceolate, veined with brownish purple; inner segms. lanceolate, spreading, faintly veined. Gt. 35: 1222 (as I. Douglasiana) —An iris of the apogon group closely related to I. bracteata from which it differs by the long linear perianth-tube.—*I. ténuis,* Wats. Rootstock slender, wide-creeping: lvs. thin, ensiform, 1 ft. long, ½in. broad: st. equaling the lvs., branched: spathe-valves scarious, 1 in. long, 1-fld.: outer segms. oblong-spatulate, white, yellow at the throat and marked with purple veins; inner segms. smaller, erect, emarginate. Ore. G.F. 1:6. Apogon.—Rare, found only in Ore., and not in cult. except possibly in collections.

Two Chinese species recently offered in England are *I. Bulleyàna,* Dykes. Foliage grass-like: fls. described as of pretty form though not striking, deep blue; standards blue-purple and falls mottled with same color on creamy ground.—*I. Fórrestii,* Dykes. Lvs. grassy, linear, 12 in., glaucous beneath: sts. numerous, about 12 in.: spathes green, with 1 or 2 fls.: falls with veins of dark red or purple-brown; blade drooping, pale lemon-yellow, sometimes with purplish veins. G.C. III. 47:418.

HEINRICH HASSELBRING.

IRONWOOD: Usually *Ostrya virginica;* in S. Calif., *Lyonothamnus floribundus*; in Ariz. *Olneya Tesota*; in Texas, *Bumelia lycioides.* Many hardwooded plants bear this name.

IRRIGATION. Irrigation in its broadest sense includes all problems of collecting, storing, delivering, and applying water to the land through the construction of dams, reservoirs, canals and laterals, and the application of power when necessary to deliver the water; while in a restricted horticultural sense it is a method of cultivation, having for its object to increase and regulate the water-supply in the soil.

In this latter sense, irrigation is a necessary practice in the arid regions, and is advisable in the humid regions in proportion to the intensity of the cultivation and the value of the crop grown. Thus in Florida, with an average of 60 to 70 inches of annual rainfall—usually well distributed—irrigation has been largely introduced in the past few years for horticultural crops and even for tobacco, as an insurance against loss or damage by the occasional droughts. The first cost of a small irrigation plant in Florida, for 20 acres or over, is said to be approximately $100 to $150 an acre; the interest on which, and the necessary repairs, would amount to $5 to $10 an acre each year. This is a small expenditure to insure a crop against loss or injury where the value to the acre is so great as in many horticultural lines. Irrigation is needed not only to prevent the actual death of the plants, but to promote a uniform, rapid, and continuous growth, which is necessary for the development of the finest texture or flavor of the commercial crop.

King has shown that the value of a crop saved in Wisconsin, such as the strawberry, in a season when the crops generally are injured by drought, may pay all the expenses of the original cost of the irrigation plant.

In the semi-arid regions west of the 100th meridian, with a rainfall of 20 inches or less, crops are liable to be entire failures three or four years out of five; while with an irrigation plant there should not be a failure one year in five. In the arid regions with less than 15 inches of rain, irrigation is a necessity on most soils. Here the work has been highly organized and systematized, so that the cost of water delivered at the field amounts to $2 to $5 an acre each year. Under skilful management, the most abundant yields are secured. The most careful management is required in the application of water to prevent serious injury to the land and to avoid actual injury to the crop in rendering the plants tender and liable to disease, and in maintaining the quality and flavor, both of which are liable to depreciate unless good judgment is displayed in supplying water.

Sources of water-supply.

The principal sources of water-supply are streams, surface wells, artesian wells, and the storage of storm waters. For small irrigated tracts near cities, the city water-supply may often be used to advantage. In other localities the nature of the conditions will determine the most economical source from which to secure the water. Perpetually flowing streams, if situated in such a way that water can be carried to the land by gravity, have the advantage of cheapness of construction and maintenance. On the other hand, if the stream supplies others in the community, there is liable to be trouble and expense in establishing and maintaining water-right claims and in securing water when needed for the crop. Questions arising out of the water-rights on streams and rivers in the western states, with the various state laws, the multiplicity of court decisions on the most intricate legal questions—both in different states and different countries along the line of the stream—the absence in most states of adequate police or judicial powers vested in the irrigation commissioner, have led to the most perplexing and bewildering state of affairs, and have involved the states and individuals in enormous costs for lawsuits, resulting in many cases in the apportionment of many times the volume of the stream to the settlers along its bank.

The large planter must seek some perennial and abundant supply of water, as is furnished by streams, but it is safe to say that all streams of any size in the western part of the United States are already appropriated to their fullest extent, although the water so appropriated is not all in present use. Smaller planters are much more independent with some of the other sources of supply mentioned above. Wells from 10 to 20 feet deep, with pumps operated by windmills, or wells of a maximum depth of 50 feet operated by many forms of gasolene, hot-air or portable engines, attached to direct-acting pumps or centrifugal pumps, form in general a very satisfactory means of irrigating small areas.

Over limited areas artesian wells have been very successfully used. If they are flowing wells delivering a considerable stream, they can be used over small areas without storage reservoirs, or over much larger areas with reservoirs. They should be capped in all cases, where possible, so that the flow can be stopped when not actually needed.

In many places it is possible, at a comparatively small expense, to construct a dam to collect the storm waters. The magnitude and expense of such work will depend entirely on the configuration of the surface, the area of the watershed, the volume of the water to be handled as well as the nature of the soil, and the material out of which the dam is to be constructed.

Methods of raising water.

Various methods are used for raising water from streams, wells, or storage reservoirs which may lie below the general level of the land to be irrigated. Hydraulic rams are sometimes used for small areas, but these are not economical when a small volume of water is at hand, as only about one-seventh of the water can be collected. Open buckets carried on an endless belt, operated by either windmills, or steam-power or even horse-power, are used with success and offer the advantage of cheap construction. The ordinary cylinder or plunger pumps are usually employed when the water has little or no sediment, and are operated by windmills or by steam or other form of engine. When the water carries considerable sediment such pumps are liable to wear away rapidly, and the centrifugal pump is the most economical form to use. The relative first cost of equipment for pumping with windmills or with gasolene or hot-air engines of approximately equal horse-power is about the same. The windmill, however, is dependent upon a mean velocity of wind of about 8 miles an hour, while the engine may be operated at any time, and is thus more reliable when either form of motive power is taxed to nearly the extreme limit. There are many kinds of windmills on the market, and many forms of home-made construction are in use

Storing and conducting water.

Storage reservoirs for streams and for storm waters vary in size and in cost as well as in mode of construction according to the character of the land, size of area, volume of water, nature of the material of construction, and demand for the water. The construction of such reservoirs sometimes involves engineering problems of the most difficult kind, demanding the expenditure of immense sums of money.

In the use of windmills, it is necessary to have small distributing ponds or tanks, as the direct flow from the pump is usually so small and varies so much with the velocity of the wind that it cannot be depended on to water any considerable area. Where it is stored it can be turned out on the land in large volumes, so that it spreads over the surface and waters the whole area uniformly. For an ordinary windmill the ponds are from 50 to 100 feet square. They can be stocked with fish and thus be a source of some revenue and variety in the family supplies. Unless the pond is situated on a slight elevation, the earth for the embankment must be taken from the outside. The banks are usually made with a slope of 1½ to 1 foot. For a bank 5 feet high and 2 feet across the top, the side would be about 7½ feet and the base about 13 feet wide. If the ground is at all pervious to water, the bottom of the pond should be protected from undue seepage and loss of water by puddling. This should be done with clay, if this is obtainable. This puddling is often done by driving horses or cattle in the pond while the surface is wet. A pond of the size indicated above, operated by a windmill where the mean wind velocity is about 8 miles an hour, will irrigate from 3 to 5 acres of land in the semi-arid regions. Such a pond could be counted upon to irrigate from 5 to 10 acres where, as in the East, only one or two irrigations would be required during the season. The size of the reservoirs and the area they will irrigate, when supplied by steam or other kind of engine, will depend upon the available water-supply and upon the size of pump and power used.

Ditches and flumes.

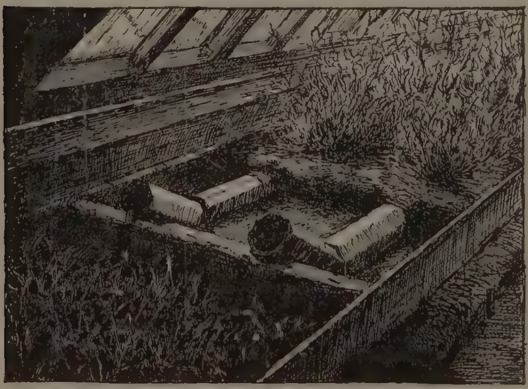
The water is usually carried from the stream or storage reservoir by gravity in open ditches. This involves loss by evaporation from the surface and by seepage through the soil. When the water-supply is limited and its value is consequently great, terra-cotta pipes, iron pipes, cement or wooden pipes may be used. When the surface of the country is uneven and ravines have to be crossed, flumes are used to carry the water on an even grade across the depression. These flumes may be iron pipes, open wooden troughs, or wooden pipes held together with substantial hoops. If the depression is not too great the ditch may be built up on an earth embankment. When the water has to pass through a gravelly soil, or when for other reasons the soil is very pervious, special precautions should be taken to prevent seepage by using pipes, cementing the sides of the open ditch, or puddling the ditch with clay or similar material.

Application of water.

The water is usually applied to the ground by flooding over the whole surface. For this purpose the surface must be perfectly level and the ground carefully prepared, so that the water will flow uniformly and quickly over the entire area and be of uniform depth throughout. When crops are cultivated in rows or on beds, the water is allowed to flow down in the troughs between the rows, and there must be a sufficient head of water to reach the ends of the rows in a reasonably short time, so that the whole width of the field will be properly watered.

Where the surface of the ground is so uneven that surface flooding cannot be used, basins are formed by throwing up slight ridges, with a plow or other implement, and the water turned into these basins in succession and allowed to accumulate to a sufficient extent. This method is particularly applicable to fruit trees, although it is occasionally used in other crops. In very sandy soils the water is occasionally carried through the field in wooden troughs, which admit of sufficient seepage to water the land. This prevents the undue seepage which might occur in such soils if the water was flowed over the surface. Another method is to distribute the water through the field in iron pipes, with openings at frequent intervals, in which nozzles can be attached to deliver a fine spray over a small area. With four or five such nozzles an attendant can water a considerable area of ground in the course of a day. Such an irrigating outfit in Florida was supplied with a power equivalent to about one horse-power an acre. The mains and laterals were of 1-inch or 1½-inch iron pipes laid near the surface of the ground, the laterals about 100 feet apart, with hydrants every 50 feet. Tanks were originally used, but it was found desirable to pump directly into the mains to insure a sufficient pressure.

Care should be exercised in applying water to the land. Where water is plentiful there is a common practice of using such an excess as to injure the flavor of fruit, increase the liability of disease, and eventually injure the land by the accumulation of seepage waters and of alkali. As a rule, there has been very much more damage from over-irrigation than from the use of too little water. The first two or three years a soil usually requires a considerable amount of water, but after becoming well moistened to a considerable depth it should require comparatively little water thereafter to maintain its fertility. As it is not easy to apply just the proper amount, the excess should be provided for. If there is any reason to fear lack of drainage, the land should be thoroughly underdrained before irrigation is started, or at any subsequent time when the need of it becomes apparent.



1979. Sub-irrigation with two runs of tile.

Irrigation always should be supplemented by the most thorough cultivation. After going to the expense of watering the soil in this way, it is poor economy to allow the water to escape by evaporation or otherwise; therefore every precaution should be used in thorough, subsequent cultivation and in the exclusion of weeds, to conserve the moisture so applied. The intelligent horticulturist will find that in the use of this expensive method of maintaining a proper water-supply in the soil, it is incumbent upon him, even more than if the method were not used, to give careful attention to all the ordinary methods of preparation and cultivation in order to maintain the advantages he has established by the irrigation plant. MILTON WHITNEY

Sub-irrigation in the greenhouse.

The term sub-irrigation is used to describe a method of supplying water to the roots of plants by means of some form of conduit placed below the surface of the soil. In greenhouse operations, the essential features of the plan are a level water-tight bench-bottom, and tile, or pipes, to serve as conduits for the water. The tile, or pipes, are laid directly on the bench-bottom, and over these the soil is spread, usually to the depth of about 6 inches. When water is introduced in sufficient quantities through the tile or pipes, it passes out at the joints, or perforations into the soil.

When applied to greenhouse operations, the term sub-watering has been proposed by E. S. Goff, for the reason that irrigation is used to denote watering on a large scale out-of-doors. It may be said, however, that the words watering and irrigation do not indicate the scale of operations with any degree of accuracy; therefore it seems as well to use an old word as to coin one, especially when the familiar word expresses the meaning intended.

Experiments in watering plants by this method were begun in the winter of 1890 and 1891, at the Ohio Experiment Station. The suggestion came from the result obtained in an effort to check the lettuce rot. Water was introduced to the soil in boxes by means of a pipe, in a manner similar to the method often employed in watering hills of melons and cucumbers. When the plants were watered in this manner, the lettuce showed so much more vigor than that watered in the ordinary way, that operations were begun at once on a larger scale; first in a bed on the ground having a clay bottom, then on a water-tight bench, made of lumber, and finally, on tile benches, covered with cement.

In all of the earlier experiments the water was introduced through pipes, or drain-tile, laid about 2 feet apart on the bottom of the benches. Goff has used brick instead of tile, placing them near enough together to touch. They were set on edge in a galvanized iron pan, made for the purpose. J. C. Arthur clipped off the corners of the bricks, so as to facilitate the flow of water. The Ohio Station has modified this plan by using common drain-tile, laid so as to touch, thus covering the entire bench bottom, instead of lines of tile every 2 feet, as at first.

Benches made of lumber have proved unsatisfactory because of the swelling and warping of the boards. Solid beds on the ground have not been successful, except where an impervious clay bottom existed. Galvanized iron adds greatly to the cost of construction, and lasts only a short time. The only suitable bench for greenhouse sub-irrigation is one made of materials which are not acted upon by water.

A well-made tile-and-cement bench seems to be the only form of construction that will meet the requirements. Such a bench does not cost so much as to preclude its use, and will last as long as any other part of the greenhouse. In describing such a bench, it will not be necessary to enter into details, except such as relate to the method of watering under discussion. The bench must be water-tight, and this essential condition is secured by spreading a layer of cement, an inch or more in thickness, over the tile bottom. It is not a matter of any moment whether flat tile or common drain-tile are used, except in the quantity of cement required. The cement must be spread with care, so as to secure a perfectly flat level bottom, otherwise the water will not flow uniformly in all directions. The sides of the benches are made of cement also, but need be only 2 or 3 inches high, or of sufficient height merely to retain the water. Boards or slate are placed outside the cement wall to retain the soil. The tile-bottom may rest on iron or wood cross-pieces. Wood has been in use for this purpose at the Ohio Station for twenty years and shows no signs of decay, because it is out of reach of the water.

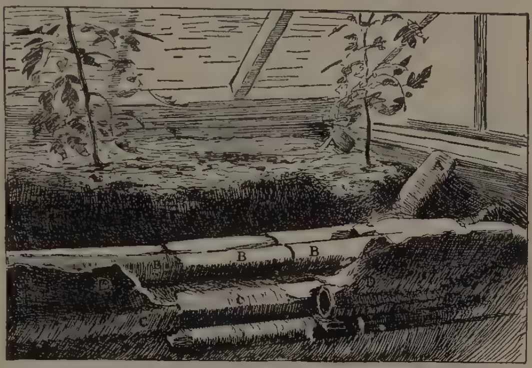
Twenty years' experience shows that a perfectly constructed bench-bottom, with the tile laid 2 feet apart, will serve satisfactorily in distributing the water to all parts of the bed, provided the tile are straight, so as not to impede the flow of water. The tile are laid in the same manner as tile-drains, and lengthwise or crosswise the bed, as preferred. Better results are usually secured if they are laid crosswise than lengthwise, as it is difficult to secure an even flow from long lines of tile. A little cement or mortar is used at each joint simply to hold the tile in place when the soil is put in the bench, but not enough to impede the flow of water from the joints. The first tile where the water is introduced is laid at an angle, one end resting on the edge of the bench side. This leaves a wide opening at the first joint, which is closed with cement. A better plan is to use a curved sewer-pipe for the inlet, but this is not always available. The picture (Fig. 1979) shows how the tile is laid on the bench bottom, being a view of a side bench in a carnation-house.

Following Goff's suggestion in the use of brick, tiles have been used over the entire bench-bottom with good results, and it seems probable that this will be found to be the best form of construction, as it appears more certainly to insure an even distribution of water. The method of construction is the same as above described, for the two plans differ only in the number of tiles employed to distribute the water. When the bench-bottom is covered with tile, placed near enough together so that the soil will not fall between, it will readily be seen that water introduced at any point will flow to all parts of the bed in and around the tile. It needs simply to be brought up to such a level that it will reach the soil, when capillary attraction will complete the distribution. Fig. 1980 shows a bench in a tomato house constructed after this plan. *AA* are the inlets; *B* the irrigating tile, from which the soil has been removed; *C* is the tile bench-bottom, covered with cement. The same size of tile, viz., 2½- or 3-inch, is used both above and below. *D* is the cement side, which has been broken away to show the method of construction. The outer board has been removed also.

The cost of construction need not be discussed here, except to state that the only items extra, more than are required in any well-constructed greenhouse, are the cement bottom and the tile in which the water is distributed.

A plan has been devised for applying water to small plants in flats which may properly be mentioned under this head. The flats are shallow boxes with slatted bottoms. When the plants require water, the flats are placed in a shallow vat of water and allowed to remain until the surface of the soil appears to be damp, or even wet.

A watering in this manner is far more efficient than by the ordinary method. Taken in connection with sub-irrigation in the benches, a crop of lettuce can be brought to marketable size nearly two weeks earlier than when surface-watering is practised. Anything like a full discussion of results of experiments in watering plants in the greenhouse by sub-irrigation would be too voluminous for an article in this connection. A brief review of the results obtained at some of the stations, together with a short discussion of some general principles, will serve the purpose intended. The increase in weight of lettuce from sub-irrigated plats over those watered in the ordinary manner has been reported by Rane, as 25 per cent and by Goff and Cranefield as 26 per cent. At the Ohio Station the range has been from 25 to 100 per cent. In the latter case the result was obtained by commencing with the plants as soon as taken from the seed-bed, and carrying the two lots through to the termination of the experiment, one by watering altogether on the surface of the soil, the other by subirrigation. Each of the experimenters speaks of a gain in earliness of several days, by sub-irrigation. Rane secured similar results with long-rooted radishes by this method of watering, but not with the turnip-rooted sorts, while Munson doubled the crop by watering below. Better results have usually been secured at the Ohio Station with the turnip-rooted than with the long varieties, but in all cases there has been a gain in favor of sub-irrigation, varying from 50 to 100 per cent. Rane found that sub-irrigation increased the yield of tomatoes, but the gain was not large. Essentially the same results have been secured in Ohio. The tomato crop has not been greatly influenced by the manner in which the water was applied, and the same is true of beets, while sub-irrigated cucumbers and parsley have shown a decided gain over surface-watered. Carnations, roses, chrysanthemums, sweet peas, violets and smilax have been under experiment by the two methods of watering, and while no such marked results have been secured as with lettuce and radishes, the sub-irrigated plats have shown superiority over those watered in the ordinary manner, in nearly all cases. With carnations the improvement has been mainly in length and stiffness of stem.



1980. Sub-irrigation with several rows of tiles.

Aside from the increase of crop secured by sub-irrigation, there are other considerations which may be urged in its favor, and these are embodied in the following general propositions:

1. *Watering by sub-irrigation in the greenhouse saves labor.* The amount of labor saved depends mostly upon the completeness of the arrangements for watering, but there is a saving in the number of applications as well. It is possible to reduce the time employed in watering a house, or series of houses, to one-fifth the time usually required.

2. *Watering by sub-irrigation assures an abundant and uniform supply of water to all parts of the bed.* Perfect construction of the benches is assumed in this case, but with such construction watering becomes almost automatic, the only care necessary being to look after such portions of the beds as may, by position, be subject to unusual conditions of air or sunlight.

3. *Where sub-irrigation is practised in the greenhouse, the surface of the soil does not become compacted, but retains its original loose, friable condition.* It is true that where frequent syringing is practised the surface of the soil becomes more or less hardened, but not to the extent that occurs in surface-watering, and the condition is easily remedied, whereas in the other case it is not. It follows that a heavier soil may be used for sub-irrigation than with surface-watering.

Still other considerations might be urged in favor of this method of watering, but many of them would apply to special cases only. Regarding the effect of the method upon insects and diseases, but little can be said. Lettuce rot is less prevalent upon sub-irrigated plats than upon those which are surface-watered, but in extreme cases plants succumb to the disease, whichever method of watering is practised. Munson found that radishes suffered more from the attacks of millipedes upon sub-irrigated plats than upon plats watered in the usual manner. Nematodes work upon the roots of roses, whichever way the plants are watered. The manner of watering has no apparent effect upon the red-spider. Even in houses watered wholly by sub-irrigation this pest is no worse than in houses where the water is applied to the surface of the soil. It may be said, however, that nearly all classes of plants are more easily kept in a healthy growing condition, and are thus better able to resist enemies of all sorts, when sub-irrigated than when supplied with water in the ordinary way.

This method of applying water to plants in greenhouse benches has now been sufficiently tested to determine its value. All that now remains is to devise ways and means to utilize what is known concerning it. The adaptation to suit particular cases must be made by individuals, but this will be far easier in the future than in the past, because better methods of construction prevail than formerly. The success of sub-irrigation in the greenhouse is now simply a question of mechanics.

W. J. Green.

Irrigation for vegetable-growers and other gardeners.

In this Cyclopedia, it is not the purpose to discuss the general agricultural practice of irrigation but rather those phases that apply particularly to gardening operations. In arid countries, the garden irrigation practice will naturally follow the general methods of the region. In humid countries or regions, the practices may be very special. In the growing of strawberries and garden vegetables in the eastern United States, special irrigation practices are developing, and these may be briefly considered.

Success in crop-growing depends on many factors. If one of these factors is deficient to such an extent as to limit the crop in yield or quality, no excess of the other factors will suffice to make up the lack. Thus, if nitrogen is present in the soil in only very minute quantities, no amount of phosphorus or potash will enable the plant to offer the husbandman a worthy harvest. In vegetable-gardening the amounts expended in making the various conditions favorable are relatively large. Accordingly, if one factor is deficient, the loss is very heavy. Perhaps the moisture factor is more often to be charged with the responsibility for poor returns than any other single deficiency.

We are told that 10 inches of rainfall in a year is sufficient for the production of successful crops under the methods of dry-farming. We are told that 20 inches of precipitation is sufficient for the production of successful crops under ordinary farm methods—provided it is well distributed throughout the year. Most places in the eastern states enjoy from 30 to 40 inches of rainfall a year. Nevertheless, there is hardly a season in which crops, and especially vegetable crops, do not suffer for lack of moisture during at least a month. The solution of this seeming paradox lies in the fact that our rainfall is poorly distributed through the growing season. We may have as much as 9 inches in a single month, and occasionally less than 1 inch. The total for three months in succession may be as low as 4 inches. Even such a condition as this does not frequently appear upon the weather records; for a period of drought may be followed by torrential rains sufficient to make up the average rainfall after the harm is done.

In view of these conditions, it is necessary that the vegetable-grower take measures to prevent the loss, through lack of sufficient moisture, of all the time and money that he has invested in land, tillage, fertilizer, seed, planting, cultivation, and care, to say nothing of the loss of the profit which he may reasonably expect. He may accomplish much by so managing his land as to conserve to the utmost the rainfall that is his. He may leave his land rough over winter to prevent run-off, he may harrow frequently till planting time, he may maintain an effective mulch throughout the season; even so through lack of rainfall—through absence of moisture to be conserved—he may lose his whole crop or so much of it that he might better have left the ground unplanted.

Within the past ten years, the possibilities of irrigation have become apparent to many vegetable-producers. They have found that the elimination of the moisture factor as one of the obstacles to successful crop-production has made possible larger yields, better quality and early maturity, with all the advantages in economy of management and in returns that accompany these gains. Irrigation has proved of especial value when sowings are made in midsummer for autumn maturity, at transplanting time, and as crops approach harvest.

Surface irrigation is practised to a very limited extent in the East. The method consists in conducting water along the end of the plat to be irrigated and allowing it to flow into furrows between the rows of the crop. It is best to permit the water to reach the far end of the row as soon as possible and then allow it to be absorbed evenly throughout the length. If this is not done, the part of the field next the supply-ditch will receive much more water than the remainder. This form of irrigation is useful on level land where there is abundance of water and where the soil is suitable. Light soils drink up the moisture so rapidly that an even distribution of the water is difficult and uniform results may not be secured.

Boston gardeners employ hose in watering their plantations. A system of underground pipes is installed in such a way that 50 feet of hose will reach all parts of the block. The cost of installation for the first acre is reported in a Massachusetts bulletin as being about $65 and successive acres may be piped for approximately $50. An acre may be given 1 inch of water by one man, using 1¼-inch hose, in five or six hours. Hose irrigation is objectionable on account of the disturbance of plants, the danger of injury to the physical condition of the soil, the amount of labor, and the frequent replacement of hose.

Sub-irrigation is practised in certain districts of Florida and on some muck land areas in the North. In the Sanford, Florida, district, which is typical, the water-supply is from artesian wells. The land is underlaid with tile which is accessible at both its highest and its lowest points. Thus it serves for both watering and drainage. The impervious bottom which underlies the soil is essential for the successful operation of the plan. On the muck lands of the North, the object is accomplished by closing the drainage outlets and so raising the water-table that the surface soil is moistened. It is not good practice to keep the water-table high, because it inhibits the proper root-development of the plants.

Growers of vegetables in the eastern half of the United States are using various types of overhead irrigation far more than other methods. These systems usually involve the establishment of lines of pipe mounted on posts and carrying either sprinklers or small nozzles. These lines are so spaced that the ground may be evenly covered by the spray. Some types of sprinklers are so constructed as to revolve and cover an area of perhaps 25 feet radius. These are objectionable because they cannot cover the ground as evenly as other types.

More commonly employed are small nozzles which consist merely of a threaded plug of brass through which a straight hole is accurately drilled. These are set in holes in the pipe-line. Recently various modifications and improvements in these nozzles have been made. The nozzle line is screwed together and mounted on the posts, and a special machine equipped with a small level is used for tapping and threading the holes. The nozzle line is mounted with a union in which is set a handle for turning to cast water far to each side or to cover the near gound by throwing vertically. The nozzles are usually spaced about 3 feet apart and throw a fine solid stream which breaks at some distance from the opening. When the water reaches the ground, it is a fine mist similar to a light rain. Twenty-five to forty pounds of pressure is sufficient to cover a belt ranging from 20 to 30 feet on either side of the line.

A long line, of say 300 feet, would consist of 100 feet of 1¼-inch pipe, 100 feet of 1-inch pipe, and 100 feet of ¾-inch pipe.

Nozzle lines are supported in many different ways. The consensus of opinion at present is that they should be about 7 feet above the ground to avoid interference with work that is being done. These posts must be set 15 feet apart to carry ¾-inch pipe and a little farther apart for larger sizes. Posts of pipe or wood are most commonly used, but suspension from a cable supported by posts 100 feet or so apart is gaining in favor with vegetable-gardeners.

Occasionally, for temporary purposes, as for a single watering of young strawberry plants, the pipes are simply laid on the ground and turned by the handles in the usual way. Other growers have small horses which may be placed on the ground to carry the line temporarily. Mechanism has been devised by which a large number of lines may be automatically controlled from a single point, turning the spray constantly from one side to the other.

The main at the end of a field may be buried and the lines supplied through risers, or it may be carried on the first post of each of the rows which support the nozzle lines.

Comparatively few gardens are so located that a suitable supply of water is not available at reasonable cost. There are several possible sources. Some gardeners pump directly from streams or ponds, ordinarily using a gasolene engine and the triplex type of pump. In other sections, where the water-table is relatively near the surface, and where the ground-water is abundant, wells are sunk. Some employ a number of driven wells and gather water simultaneously from all of them. At Rochester, New York, many wells of large diameter with concrete walls are to be found. The method of sinking them is ingenious. A circular ditch of the desired diameter, say 15 to 25 feet, and about 2 feet wide and 4 feet deep is dug. In this is built by means of wooden forms a concrete ring. The lower edge of this ring is beveled outward at an angle of perhaps 30°. The ring is strongly reinforced and short bits of pipe are inserted radially. After the concrete in this ring has set and the forms have been removed, the work of digging is begun within. The earth is removed, one man seeing that it is taken evenly from the sides of the well under the sharpened edge. As the work progresses the ring sinks into the ground and radial concrete blocks are built upon it to serve as a wall. The well may be sunk to a depth of 20 or even 25 feet. The large diameter offers great gathering surface, and an abundance of water may be secured from a stratum that would not yield a sufficient amount by means of small wells.

Many gardeners in the neighborhood of cities are able to utilize the municipal water-supply, taking advantage of the low rates which are granted to large users. Some are able to procure water at a cost as low as 6 cents a thousand gallons. This is about as cheap as pumping.

Many questions arise as to the handling of irrigation-water. The practices have not been worked out nearly so fully in the East as in the West. Almost no well-planned experimental work has been conducted, and opinions among users vary greatly. Although a few prefer to apply water in small amounts and frequently, most seem to think that thorough irrigation is preferable. Most men water at night or when it is cloudy, but some do not hesitate to apply even in midday, thinking that the plants are benefited by the cooling. It is well so to plan the work that the ground will not be muddy at harvesting-time. With tomatoes, precautions must be taken against cracking. This is usually occasioned by heavy watering after the plants have been kept quite dry. Lettuce requires special care to avoid the development of rots of various sorts.

The use of irrigation-water does not relieve the grower of the necessity for good drainage or careful conservation of moisture. The former guards against overwatering or heavy rains which may come just after a thorough irrigation. The latter saves water, which is costly and keeps the soil in better physical condition.

Overhead irrigation systems are used to some extent for spraying, for the application of fertilizers, and for frost protection. In some cases the water is heated before it passes to the nozzle lines.

It makes little difference how perfect a system of irrigation equipment one may have installed, or how smoothly the pump works, or what a beautiful spray the nozzles throw on the crop if the returns are not sufficient to justify the outlay. This suggestion raises the questions of cost and of gain in market value of the crop. The first cost for equipping an acre is stated by manufacturers to be in the neighborhood of $125 to $150, making use of new pipe. Some men have economized in various ways and have achieved the desired result at lower cost, although many figures that are given are misleading because the very important labor of the owner in installing the system has been neglected.

It requires 27,152 gallons of water to cover an acre 1 inch deep. This amount of water is applied through $\frac{1}{32}$-inch nozzles at the usual spacings in eight and one-half hours. Water may be pumped ordinarily at 2 to 6 cents a thousand gallons.

Many growers can give very inspiring figures as to the results that they have secured by means of irrigation equipment. One well-known New Jersey grower is reported on first-rate authority to have secured twenty-five tons of beets to the acre and 620 bushels of potatoes from the same area. A crop of onions worth $1,500 has been taken off a 5-acre piece early enough to permit a later crop of Golden Self-blanching celery to be matured. Another grower reports that an outlay of $300 to $400 saved several thousand dollars worth of celery, whereas an unwatered acre and a half was a complete failure.

The Ontario Agricultural College reports experiments as follows:

	Irrigated.	Non-irrigated.
Maturity—		
Leaf	June 22	July 4
Head	July 10	July 26
Weight of crop—		
Leaf	20 lbs., 5 ozs.	11 lbs., 3 ozs.
Head	25 lbs., 15 ozs.	9 lbs., 1 oz.
Quality	Fine	Bitter

At the outset it was pointed out that the heavy cost involved in making conditions favorable for crop-production renders it almost essential that vigorous measures be taken to prevent loss by drought. Now that the possibilities and advantages of irrigation have been indicated, it is well to emphasize the importance of making every other condition favorable. If every factor is favorable except the moisture factor and one other, and money is invested in irrigation, and the other factor prevents the maturing of a profitable crop, the situation of the grower is worse than before by the amount of his new investment.

An application of water equal to an inch of rain over an acre requires 27,152 gallons, as has been said.

To deliver this water, No. 1 Skinner nozzles with pressure of forty pounds should be placed 4 feet apart in the line and the lines should be 56 feet apart; nine hours and twenty-three minutes at forty pounds pressure is the time required. The disharge for each nozzle is 24.1 gallons a minute.

Ninety-four and two-tenths feet of elevation gives forty pounds pressure.

A four horse-power gasolene engine and duplex pump will deliver approximately 100 gallons a minute at thirty pounds pressure, at a cost of roughly 10 cents an hour.

A 2½-inch pipe will deliver 100 gallons a minute at a distance of 100 feet, and a 3½-inch pipe is required for distances between 500 and 700 feet.

With No. 1 outdoor nozzles, a nozzle line 150 feet long may be composed entirely of ¾-inch pipe.

A line 250 feet long needs 100 feet of ¾-inch and 150 feet of 1-inch pipe.

A line 700 feet long needs 90 feet of ¾-inch, 160 feet of 1-inch, 175 feet of 1¼-inch, 175 feet of 1½-inch and 100 feet of 2-inch pipe. PAUL WORK.

ISABÈLIA (Isabel, Comtesse d' Eu, patroness of horticulture). *Orchidàceæ.* One Brazilian creeping epiphyte, 1-lvd., with small reticulated pseudobulb, said to require treatment of maxillaria. *I. virginàlis*, Rodr. Fls. white, solitary; sepals nearly equal, the middle one free, the others connate and produced into a spur; petals small, narrow, the lip upright, entire. O. 1911, p. 8.—Apparently little known in cult.

L. H. B.

ÌSATIS (ancient name, of obscure meaning). *Crucìferæ.* Herbs, for ornament and for dyeing.

Annual, biennial, perennial; erect, branching, glabrous or pubescent or rarely tomentose: lvs. undivided, the upper ones clasping and auricled: fls. small, yellow, many in lax racemes, without bracts; sepals and petals 4: pod large and mostly flat, pendulous, linear to oblong or obovate or even nearly circular, indehiscent, strong-ribbed on either side, 1-seeded, the stigma sessile; radicle mostly incumbent.—Species about 50, Eu., N. Afr., Asia.

This genus includes the dyer's woad, *I. tinctoria*, formerly cultivated for a blue dye but no longer advertised. Cæsar relates that the ancient Britons used the woad for staining their bodies, and the word Britain itself comes from an old Celtic word meaning painted. Before indigo became common in Europe, the dyer's woad produced the chief blue coloring matter for woolen cloth. The introduction of indigo in the seventeenth century destroyed this important industry, not without opposition. Dioscorides and Pliny mention both the dyer's woad and indigo.

tinctòria, Linn. Rather tall; glabrous or nearly so, and glaucous: biennial, 1½–3 ft.: st.-lvs. lanceolate, entire, sessile, somewhat arrow-shaped: fls. small, yellow, borne in early summer, on panicled racemes: instead of a pod, opening lengthwise by valves, it has a closed fr. like the samara of an ash, 1-celled, 1-seeded, indehiscent, wing-like. S. E. Eu. and probably eastward; now widely naturalized in Eu.—The cult. form is sometimes distinguished as var *satìva*, DC., with broad glabrous lvs.

glaùca, Auch. Perennial, glaucous, the st. thick, 2–4 ft., and bearing a large panicle: lvs. glabrous, entire, the radical oblong and the cauline very small: fls. yellow: pod about ½in. long, linear-oblong, obtuse or truncate-retuse. Asia Minor, Persia. G.M. 47:492.—Offered abroad.

I. Boissieriàna, Reichb. Annual, 12 in.: basal lvs. cuneate-oblong, toothed; upper lvs. entire, oblong: fls. yellow: pod pubescent, various. Turkestan.

L. H. B.

ÍSCHARUM: *Biarum.*

ISCHNÓSIPHON (name refers to the narrow corolla-tube). *Marantàceæ.* Upward of a dozen calathea-like perennial herbs or bamboo-like plants of S. Amer., belonging to that group of the family having 1-celled rather than 3-celled ovary (and so differing from Calathea and Phrynium, and agreeing with Ctenanthe and Maranta, but differing from the last two in having a solitary staminodium). Lvs. large, coriaceous or soft: fls. geminate, in an elongated cylindrical spike; sepals 3, free, long-linear; corolla-tube narrow and much elongated, the lobes lanceolate or oblong-lanceolate; stamen-tube nearly obsolete; staminodium petal-like, large, obovate: caps. elongated, very unequally 3-valved, 1 valve dehiscent. Tall often branching plants with leafy sts., very little, apparently, in cult. They are treated as calatheas or marantas. **I. leucophæ̀us**, Koern. (*Maránta màjor* and *Calathèa màjor*, Hort.). Two feet and more, nearly simple: basal lvs. ovate or oblong, acuminate, more or less cordate at base, farinose beneath: racemes simple, about 6, slender; corolla white or rose-colored, the tube upward of 1 in. long, the lobes oblong-lanceolate. Panama to Brazil. **I. bambusàceus**, Koern. (*Calathèa bambusàcea*, Poepp. & Endl.). Bamboo-like, becoming 30 ft. or more tall, much branched, with graceful shoots: lvs. small (3–5 in. long), somewhat ovate-lanceolate, attenuate-acuminate, green above and glaucous beneath: raceme short and sessile, solitary or twin; corolla-lobes whitish yellow, lanceolate, the tube exserted and about 1 in. long. Peru.

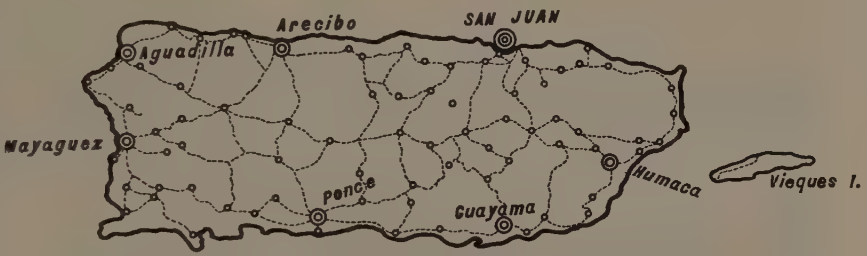
L. H. B.

ISLAND DEPENDENCIES, Horticulture in. The island dependencies of the United States comprise territories in both Atlantic and Pacific waters. They are all tropical, however, and therefore may be considered together horticulturally. The islands that call for special treatment in this work are Porto Rico, Hawaii, Philippines, Guam, and the American part of the Samoan group (Tutuila). The inclusion of these wide-scattered territories in this Cyclopedia brings in the flora of the tropics, although it is intended to discuss, in the regular entries in the different volumes, only the most important or outstanding species; to endeavor to comprise all cultivated plants that might find home or lodgment in these islands would be to describe practically all tropical subjects, and this would be far too large an undertaking for a work of this character.

The geographical articles in this Cyclopedia are gathered under three heads,—British North America, Island Dependencies, North American States. In the last symposium will also be found an account of Panama in its horticultural relations. All these articles should give the reader a comprehensive view of the horticultural possibilities of the North American continent north of Mexico, and of the tropical territories that have become attached to the United States. They depict a surprising range of natural conditions and resources, and indicate a very real horticultural conquest of a relatively new part of the earth's surface.

Porto Rico.

The island of Porto Rico (Fig. 1981) is rectangular in form, about 100 miles long and 35 miles wide. Its area is about one-twelfth of that of Cuba and nearly the same as that of Jamaica. It lies in 18° north latitude and 65° to 67° west longitude, which places it 600 miles due east of Jamaica. Although Porto Rico is mountainous, the mountains are low and rolling, but few of the short ranges exceed 2,000 feet in elevation, making practically all of the area suitable to some branch of agriculture. The low plains extending a few miles inland from the sea and reaching for the most part around the island, and the numerous plains and low rolling areas between the ranges of mountains, afford a variety of rich soils, of temperatures and of elevations, which has developed extensive horticultural interests and operations. The rainfall is generally considered heavy, although the sea-breezes and varying temperatures of different elevations cause a great difference in rainfall between different sections. In all parts of the island, excepting the western and southern areas, the rainfall is fairly well distributed through the year, although the season for heaviest rainfall is from May until December, which is the only season when the western and southern sections have an abundance of rain. In sections in which drought continues through the winter months, irrigation is often employed. The elevated sections are well supplied with rains and are drained by numerous ravines, creeks and small rivers, which afford an abundance of power and opportunity for irrigation. In inches, the annual rainfall varies from 37, in the southwestern parts of the island, to 135 on the higher mountains in the northeastern part, the average for the island being 77.



1981. Porto Rico.

The climate is healthful and delightful, the temperature being almost ideal. Because the island is small and has a moderate elevation, and lies in the zone of the trade-winds, the climate is uniformly warm and comfortable. The coolest month is January, which has an average temperature of 73°, while August, the warmest month, has an average of 79°. The mean daily temperature is quite constant, the change from day to night temperature being 20° to 25°. The average daily maximum temperature along the coast in summer is 87° and the daily minimum temperature in inland sections is 65°.

The population of the island, according to the census of 1910, was 1,118,012, which allows 320 persons to the square mile. All persons but a small percentage are engaged in agricultural pursuits.

The soils of Porto Rico are of many types, and grade from very heavy clays to light sandy loams. The hills and mountains are, for the most part, red clays, while the valleys between them and the coastal plain are heavy dark loams, grading in some places into sandy loams. While the soils are usually fertile, many crops respond to a complete fertilizer. There are practically no swamps in Porto Rico, although during the season of excessive rains ditching is necessary to drain large areas of the level coastal plains. Except in areas near the sea surface, drainage is good; however, poor drainage of the subsoil in some areas is a hindrance to horticultural crops.

Horticulturally the island is divided into three sections: The narrow sandy plains which skirt the coast are well adapted to coconut culture. The slightly elevated plains and low rolling lands between the flat coastal plains and the more elevated portions of the island on the north have been proved to be well suited to pineapple and citrous fruit-growing, while the highest mountain ranges that traverse the central part of the island are devoted almost entirely to coffee. Sugar-cane growing is confined mostly to the heavy soils of the coastal plains.

The leading horticultural crops are citrous fruits, coffee, coconuts, pineapples, vegetables, bananas and other tropical fruits. The agricultural industries are sugar-cane, tobacco-growing and stock-raising.

The most attractive field for the horticulturist in Porto Rico is citrus-culture. This industry has made wonderful progress since the American occupation, over 3,000 acres now being given up to it, while there were no commercial groves at the time of the occupation. Grapefruit, oranges, lemons, limes and other less important citrous fruits are cultivated, although attention is given mostly to grapefruit and oranges. In the area adapted for citrus-culture, the temperature is ideal for tree-growth and fruit-production. Care must be taken, however, in selecting the orchard site to secure subsoil which will drain well and areas protected from the winds. The trade-winds are in some places constant enough to hinder a normal tree-growth and to prevent the best development of certain fungi which prey on injurious scale insects. Where there is not natural wind-protection, a belt of tall-growing trees is planted on the windward side of the grove for shelter. Several leguminous crops, such as jack beans, velvet beans and cowpeas grow to perfection and are used extensively as cover-crops and green-manure crops.

Four ship lines furnish excellent transportation between the island and New York, the ocean rates being much less a box to New York than from Florida or California.

Grapefruit seems to be especially well adapted to Porto Rico conditions and is receiving first attention among horticultural crops. The trees are very vigorous, come into bearing early and are very prolific. The quality of the fruit is excellent and Porto Rican grapefruit is throughout the year a favorite product in the northern markets. The fruiting season for this crop is very long. The main crop is harvested during the winter and spring months but each week throughout the year Porto Rican grapefruit is offered on the market. Varieties "Duncan" and "Marsh Seedless" are the most popular.

Oranges have been more extensively planted than grapefruit though they do not seem so well adapted to the conditions, and the planting of them has practically ceased. Like grapefruit, the trees bear early and are prolific, and the fruit is of a high quality. Dis-

1982. A native hut in Porto Rico.

eases and insects cause but little damage. Oranges are found growing wild throughout Porto Rico, though most numerous through the western mountains, which are planted to coffee. These wild orange trees, grown under the protection of the coffee shade trees, produce a beautiful clean fruit which matures during the driest season and develops an excellent flavor and quality. These wild oranges are given no culture and the fruit is sold on the tree by the coffee plantation owner to packing firms in the western seacoast towns, who box and ship them to northern markets. Until within late years, unexperienced packers have brought Porto Rican wild oranges into disrepute by shipping great quantities of poorly packed or immature fruit, which reached the market in bad condition. The lack of good roads into the interior of the island prevents the marketing of thousands of boxes of fruit annually and allows quantities of boxes to be bought for a few cents a box. While the wild fruit is handled for the most part by the natives of the island, the cultivated oranges and grapefruit are practically all grown and marketed by Americans.

Pineapples have been one of the most profitable crops in Porto Rico for several years, as the price of the fruit has been high and weather conditions favorable for production. The old Spanish belief that pineapples were not profitable except in the locality of Lajas, a town in the western part of the island, was soon disregarded by the American settlers and at present this crop is found in many parts of the island. The commercial plantings are confined to two varieties, the Cabezona, meaning in English "large-headed," and Red Spanish. The former is grown for canning and the latter for shipping fresh. Most of the Red Spanish variety is grown in sections near Rio Piedras, where the soil is a light sandy loam, and from Bayamon to Arecibo, where the soil is an open, well-drained red sandy loam; however, they grow well in many other locations. The chief demands of the pineapple are well-drained, well-aërated soil, abundance of sunshine and a good supply of complete fertilizer where the surface soil is not naturally rich. This crop is practically free from insects and diseases. The plants are very prolific and can be brought into bearing at any season of the year. As the northern market shows a preference for Porto-Rico-grown pineapples, the industry bids fair to become still more important. Though the practice varies with conditions, the usual cultivation method is to plow the soil and by plow and hand labor work it into beds a few inches high, leaving ditches to afford drainage. The beds are made wide enough to provide for two to six plants set from 12 to 18 inches apart. Of the 10,000 plants to the acre, which is the number usually set, 90 per cent are expected to bear fruit the first crop. Fertilizer is applied at the time of planting and at intervals during the growth of the plant. As the first crop of fruit matures, suckers spring from the base of the plants and produce a second crop. On the most suitable land three or four crops are allowed to develop from suckers, though seldom more than two are considered profitable. The Cabezona variety is grown for canning principally, although profitable shipments of fresh fruit have been made. In the western end of the island, and especially in the area from Lajas to Mayagüez, the conditions are especially adapted for the growing of this variety. In this area a great quantity of the fruit is grown and sold to canners by the ton.

1983. A grapefruit grove in Porto Rico.

FRUIT SHIPPED FROM PORTO RICO TO THE UNITED STATES AND FOREIGN COUNTRIES DURING THE TWELVE YEARS ENDING JUNE 30, 1912.

Year	Oranges	Pine-apples	Canned pine-apples	Coco-nuts	Grape-fruit	Other fruits
1901....	$84,475	......	......	$8,334	......	$16,992
1902....	51,364	......	......	12,720	......	9,898

At the present time, the coffee industry is flourishing, as both weather conditions and prices are favorable. Aside from the influence of changing tariffs, practically the only drawback to this great industry is severe storms which once in a series of years visit the island, usually coming in the coffee-ripening season. Porto Rican coffee is not well known in the United States, but throughout the West Indies and in some European countries it is a favorite among coffees and brings high prices, selling for several cents a pound higher at wholesale than Brazilian coffee. The mountainous region of the central and western part of the island is given up mostly to coffee and affords a splendid field for its culture. The best coffee in Porto Rico grows on the well-drained upland areas and reaches its highest perfection at 1,500 and 2,000 feet. Throughout this coffee-growing area, the air is always cool and refreshing and conditions for health are almost ideal. As the coffee is prepared for market on the plantations and can be transported to the seacoast markets or to the main roads leading there by pack animals, the lack of good roads does not hinder this industry as it does others in this section. Throughout the area devoted to coffee the land is cheap, in many localities not exceeding $30 an acre. Coffee may be grown in Porto Rico for 5 cents a pound and on a good plantation from 300 to 400 pounds an acre is an average crop. At the present price of 15 cents a pound, handsome returns are realized. Practically all plantations devoted to this crop are large and under Spanish or Porto Rican management. It is a rare exception when any fertilizer is applied to coffee. As the plantations are rolling and the trees set but a few feet apart, no animal cultivation is given and the only cultural work is confined to shallow hoeing and weeding.

There is no crop in Porto Rico which yields such regular and satisfactory returns as the coconut palm. Without cultivation or fertilizing, the trees bear good crops of large nuts which bring first-class prices in the United States markets. The narrow strip of sandy coastal plain, which rarely exceeds ½ mile in width and for the most part skirts the island, is ideal for coconuts, as the sandy loam affords perfect drainage, which is the principal requisite for this crop. Most of the suitable land has been planted and is in bearing. The trees are planted from 25 to 30 feet apart each way and bear in five to eight years, depending on the fertility of the land. The area devoted to coconuts in Porto Rico is small, and practically all of the product is exported to the United States, the only demands at home being for drinking the water from the half-mature nuts and for making coconut-oil and its products.

The temperature in Porto Rico is ideal for vegetable-growing, but injurious influences of excessive rains and prolonged droughts, together with the rather heavy poorly aërated soils, make commercial vegetable-growing practically a failure so far as shipping to foreign markets is concerned. When irrigation is practised, excellent crops of lettuce, radishes, turnips, carrots, tomatoes, peppers, cucumbers, and so on, are grown, but usually at a cost so high that export is not profitable. Large quantities of vegetables are grown and sold at a very low price for home consumption. The most productive crops and those that can always be depended upon are the starchy root crops including ñame, yautias, dasheens and yuca. These products are not exported, although they are grown by every Porto Rican family on the island where the farm or dooryard is large enough for them. One exception is yuca (Manihot) which is grown by commercial firms and the starch extracted in a modern factory near Bayamón.

Bananas are found growing in all parts of the island and form a part of the daily diet of both Porto Ricans and foreigners. They are grown in dooryards, along streams, in orchards, as windbreaks for young citrous trees, as shade for newly planted coffee trees and throughout the hilly coffee plantations. A number of the best varieties, including yellow- and red-fruited kinds, and those for eating raw and for cooking, may be found in plenty on nearly every farm.

As is true with other West Indian Islands, the mango is the most popular fruit. It is truly the apple of the tropics. Until late years but little has been done to improve the quality of mangoes in Porto Rico, and there are but few of the choice strains growing here. The favorite kinds grow in the Mayagüez district. The fruiting season continues for several weeks during which time this fruit is one of the chief articles of food among some of the poorer classes. No effort is made to export the mango. At home they are used only in the fresh state except that fully grown green fruit is made into sauce which resembles apple sauce very closely, both in appearance and flavor. No orchards of native mangoes are cultivated, as the trees grow wild and produce well with no care. The federal experiment station and a few commercial fruit-growers are introducing and distributing superior varieties from other countries, notably East India and the Philippine Islands. These imported varieties are thrifty and the fruit of a very superior quality.

The avocado tree requires a well-drained soil and prefers one of a rich neutral loam. It does not grow well on all parts of this land and reaches its heaviest production on the west end of the island near Isabella and Aguadilla. The fruits are so plentiful, however, that those of highest quality may be purchased in markets at 1 or 2 cents each during the few weeks of harvest. Among other fruits that may be found in quantity in the markets of the island are mamey, anona, caimito, nispero, papaya and guayaba.

Among the agricultural industries, cane- and tobacco-growing and animal-production are important undertakings. Most of the cane is grown on the low coastal plain which reaches around a large part of the island and in some places is several miles in width. In these areas the soil is well adapted to the industry and as the temperature is even and never low a good yield can be depended upon each year. In 1901, the exports of sugar were less than 70,000 tons; in 1911 they were nearly 323,000, and during 1912, 367,000,—five times greater than they were eleven years ago,—and they are still increasing, having advanced 10 per cent during the past year (1913). The external sales of this product yielded $31,500,000 against less than $5,000,000 in 1901.

1984. A pineapple field in Porto Rico.

Tobacco is grown to some extent in all parts of the island, though most of the Porto Rican output is grown in the vicinity of Cayey, Caguas and Gurabo. In these sections an excellent product is grown and it is the chief industry. Quoting from the report of Governor Colton for 1912,—"The output of cigars was more than fourteen times greater than in 1901, since which year it has continuously increased until the sales of 1911–12 reached 281,000,000, an increase of 10,000,000 over the preceding year. Of these 170,000,000 were consumed upon the mainland and 111,000,000 in Porto Rico."

Great interest is shown by the people of the island in promoting scientific agriculture and agricultural education. Institutions engaged in this work are the Federal Experiment Station, an Agricultural College, a Sugar Producers' Experiment Station supported by the sugar-growers, and a Board of Agriculture.

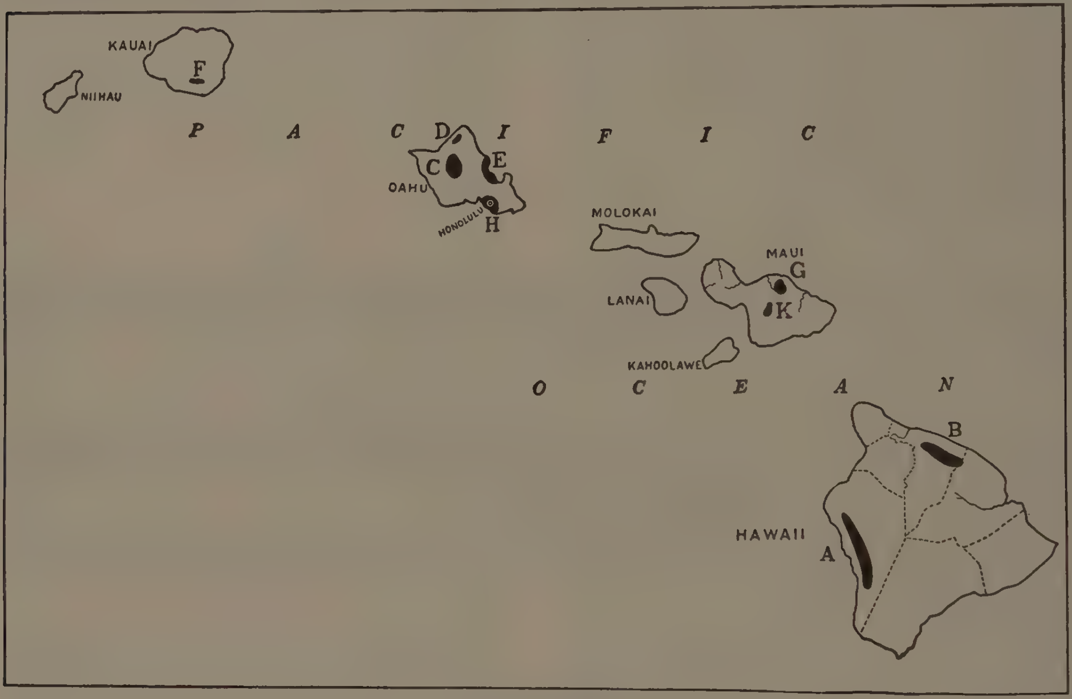
C. F. Kinman.

Hawaiian Islands.

The group known as the Hawaiian Islands (Fig. 1985) is located about 2,100 miles from San Francisco in a southwesterly direction. These were named the Sandwich Islands by the discoverer, Captain Cook, but this designation was abandoned many years ago for the original native name, taken from that of the largest member of the group, Hawaii. Since annexation to the United States, the Hawaiian Islands have been officially known as the Territory of Hawaii. Disregarding small and unimportant islands, Hawaii lies between the parallels 18° 50′ and 23° 5′ north latitude and between the meridians 154° 40′ and 160° 50′ west longitude. The five most important islands have an area of about 6,200 square miles, or rather less than that of Massachusetts, and extend about 380 miles from northwest to southeast.

It is hardly correct to speak of the climate of Hawaii, for there are so many different climates in this small area. The extent of the rainfall, for example, which forms so important a factor in the horticultural conditions of a country, is decidedly divergent in different regions and even in localities within a few miles of each other. To understand the climatic conditions, it is necessary to recall that these islands are of volcanic formation, their central parts and the larger part of their area being occupied by rugged and high mountains, descending sometimes gradually, sometimes precipitously to the sea and with valleys or tablelands lying between the ranges and narrow plains near the coast. Being in the path of the northeast trade-winds, the windward side of the islands receives an abundant rainfall throughout the year, while the southwest shores are comparatively dry. Thus, at Honolulu, on the southwest shore of Oahu, the annual rainfall averages about 38 inches, while that of the city of Hilo, on the windward side of the island of Hawaii, measures 12 feet. Even within a very narrow range, as, for example, the limits of the city of Honolulu, there is great variation in rainfall, certain localities receiving frequent rains throughout the year, while others only 2 or 3 miles distant practise irrigation constantly. Some of the great sugar-cane plantations depend wholly upon the natural supply of water, while others could not grow cane at all without their expensive systems of artesian wells and irrigation.

Similarly there is a great variation in the temperature in different parts of this small but important country, but exceedingly slight variations with the changing seasons. The windward side is cooler than that which is sheltered by the mountains, but in no part of the islands is the heat so intense as would be expected from their location within the tropics. Only rarely, in the hottest localities, does the mercury rise to 90° F. Again, the variation in elevation from sea-level to many thousand feet gives a like variation in temperature, so that some of the mountains of the largest island are covered with snow during a part of the year. In short, so far as climate is concerned, the Hawaiian Islands offer all that could be asked for great and diversified horticultural industries.



1985. Hawaiian Islands.

Only a small proportion of the total area of the country is suitable for cultivation. The lands lying near the shore and along the lower slopes of the mountains are occupied almost exclusively by sugar-cane, with an occasional banana plantation and with rice and taro growing on the low valley bottoms which can be kept submerged for these aquatic plants. The cane-belt rises to an elevation of only a few hundred feet on some plantations, limited by the cost of pumping water, but in some other localities it extends to nearly 2,000 feet. These lower lands are well adapted to the growth of tropical fruits and such, together with many of the vegetables and flowers of the temperate and tropical zones, may be found in gardens. Above the cane-belt are lands also suited to such tropical crops as pineapples and coffee, and still higher there are some areas where apples, peaches, plums and many temperate-zone fruits may be grown, although none of these crops has become the basis of an industry. The regions on the map, designated by the letters *A* and *B* are the two most noted coffee-producing sections; *C*, *D*, *E*, *F*, and *G* are localities in which pineapple-growing has become an important industry; *H*, indicating the district lying about the city of Honolulu, locates the area where there is probably the greatest variety of introduced horticultural plants; at *K*, known as the district of Kula, on the Island of Maui, potatoes, corn and other temperate-climate crops have been grown for many years and were shipped to California to supply the needs of the gold-seekers in 1849 and the years following before the agricultural industries of that state were developed.

The growing of pineapples is not only the leading horticultural pursuit but ranks next to sugar-production among the industries of the Islands. Hawaii is widely known for its pineapples. It is only within the last decade that this crop has risen to large importance. The beginnings of the industry were near Honolulu and the first large plantation was about 14 miles from that city in a northwesterly direction, on the foothills sloping from the Koolau Mountains. A little farther to the northwest a small colony of American farmers settled at Wahiawa on virgin lands, said to be useless except for grazing. They found that the pineapple attained perfection on their lands and the industry began to extend rapidly from that center. Several thousand acres have been planted on the foothills and the plains between the mountains, and considerable areas have been devoted to the crop on the north and east sides of the island. Other centers are to be found as indicated above on Maui, Kauai and more recently on Hawaii. Only a small fraction of the crop is marketed as fresh fruit, the greater portion being sold in the can. Large canneries are in operation in all the centers of production, owned and controlled by the larger plantations. The price paid for first quality pines is about $20 a ton. The total output for the season of 1912 is estimated at a little over 1,000,000 cases of two dozen cans each and valued between $3,000,000 and $4,000,000. At the present rate of planting it appears that the annual pack will again be doubled within a few years. The products of the pineapple cannery include not only canned fruit in several forms as sliced and grated pineapple but recently the juice is being bottled in much the same way as grape juice. A syrup is also made from the juice and one factory is engaged exclusively in this business.

The fresh fruit trade is also increasing and shipments are made by nearly every steamer to the mainland, where they are distributed to all parts of the Pacific states and a few are sent to the East. Carload shipments have been made to the great central markets, but the Hawaiian pineapple-growers have devoted their attention chiefly to the more conservative method of disposing of their product as canned fruit, which has found a ready market in the United States.

Most of the pineapples are produced under the plantation system, the units varying from a few hundreds to several thousands of acres each. A few individual planters are in the business and at the present time their number seems to be increasing through the opening of homestead lands by the government.

The pineapples are grown just above the cane-belt, but in places in which water is insufficient for cane, the pines extend almost to sea-level. The soil upon which they are grown is usually rather a heavy loam, subtended often with a clay substratum. Since the plant will not endure standing water, drainage is one of the important problems. Underdrains of tile or rock are not in use, but surface ditches or depressions are provided to carry off the surplus water of heavy rains. Deep plowing is practised to break the almost impervious layer which develops just beneath the cultivator teeth. The use of giant powder for the purpose is now being tried. Both these practices can be conducted only when the plants have been removed from the fields, which it is necessary to do in preparation for replanting every four or five years.

Another problem of the pineapple-planter is to avoid excessive manganese in the soil, for the plant is very sensitive to an excess of this element. A few places in the pineapple region have been found where soils, otherwise excellent, have proved useless for this crop. It is easy to discover its presence by chemical analysis and usually by the appearance of the soil which, therefore, can be avoided or devoted to other crops less sensitive to manganese.

1986. Hawaiian vegetation. Showing the royal palm as it grows in Honolulu.

The method of culture is to set the plants in single, double or triple rows and cultivate thoroughly between them by mules and with hoes. Sheds are not thought of in Hawaii for there is never frost in the pineapple area. The first crop matures in sixteen to twenty-four months and is followed by a rattoon crop a year later. A second rattoon and occasionally a third may be taken from the field before plowing up the old plants and replanting. The Smooth Cayenne is the chief variety in cultivation, but another smooth-leaf variety has become somewhat mixed with the stock and all have passed usually for Cayenne. These are the only varieties now in commercial cultivation in Hawaii, although very many kinds have been tested and some continue in gardens.

Banana-growing is an older industry but it has not made as rapid progress as the pineapple. For several years the export trade has run from about 180,000 to 200,000 bunches a year, netting the growers about 50 cents a bunch when prices are good. Banana-growing for export is confined almost entirely to Oahu, since this is the only island which enjoys frequent and direct steamship communication with the mainland. The island of Hawaii ships a few bananas on its regular boats but these do not run with sufficient frequency to encourage extensive plantings. The fruits are shipped to San Francisco and practically all are consumed in that market or those immediately around the Bay. The bananas are grown in small plantations varying in size from 2 to 50 or more acres. They are owned and operated chiefly by the Chinese who unite in companies for the purpose. The lands occupied are generally at a low elevation, for the commercial banana does not prosper, in most parts of Hawaii, above 1,000 feet, and it is important, with so bulky a product, to be near the shipping port or a connecting railway. Most of the bananas, therefore, are grown along the line of the railway which circles one end of Oahu, or in the immediate vicinity of Honolulu. The plants are set at distances varying from 8 by 8 feet to 12 by 12 feet and receive water by irrigation, by natural rainfall or by capillarity when the plants are grown on ridges thrown up in swamp-lands with wide canals between the ridges. The Chinese or Cavendish banana (*Musa Cavendishii*), almost exclusively, is grown for export, although the Jamaica or Martinique variety, common in all the American markets, has been introduced and distributed. There are many varieties of bananas that are indigenous to Hawaii, and some of these are being cultivated in yards and gardens. One class of these varieties, known as the Maoli group, is grown in a small way commercially and finds a ready sale in the local market as a banana for cooking. These, when well baked or fried, are far more delicious than any of the bananas found in the American markets and a trade in them should be developed, for they are well adapted for shipping.

Coffee-growing is conducted as a small industry and there are a few rather large plantations. About fifteen years ago the trees were planted quite extensively and it appeared as though the crop would be exceedingly profitable; but cheap coffee imported from Brazil depressed prices in the American markets to a degree which caused the uprooting or abandonment of most of the plantings. A few of the original planters continue in the business and produce a high grade of coffee which has made a good reputation. The name "Kona" coffee has been applied to much of the product because the district of Kona on the island of Hawaii is one of the leading coffee districts. The total output for the year ending August 15, 1911, was about 5,200,000 pounds. The coffee-growing districts lie chiefly above the cane in localities which are well supplied with rain, as along the northeast side of Hawaii and in Kona on the west side.

Citrous fruits are found in yards and gardens in many varieties of orange, lemon, lime, pomelo, shaddock and other species, but there are few citrous orchards. Seedling oranges are shipped to Honolulu, in fifty-gallon casks, from Kona, where they grow in a half-wild and uncultivated condition. A few limes are also sent to this market. The oranges are of excellent flavor but because of inferiority in appearance and packing they sell at low prices.

The avocado, sometimes erroneously called the alligator pear, is found in nearly every dooryard and garden and recently a few orchards have been planted. The fruit is always in demand and sells at high prices even in the local market, good fruits bringing from 8 to 15 cents each at retail or from 60 cents to $1 a dozen on the trees. Previous to the advent of the Mediterranean fruit-fly (*Ceratitis capitata*), avocados were shipped to California and in experiments conducted by the Hawaii Experiment Station, these fruits were sent in refrigeration to Chicago and arrived in good condition. They sold at wholesale in San Francisco for about $2.50 a dozen. Satisfactory methods of propagating the best varieties and of handling the fruit were completed only a short time before the Mediterranean fly made its appearance and interest was being manifested in the planting of orchards of avocados for the marketing of the fruit on the mainland. Although the insect infests the avocado very rarely, it has been found in a few instances, which fact has placed this fruit on the quarantine list at the California ports. For these reasons, the growing of avocados, which at one time seemed likely to develop into an important industry may not be widely extended until the status of the pest is changed. There is room, however, for considerable extension to supply the growing local market and the culinary departments of ocean liners.

The mango is even more widely distributed than the avocado and prospers in a great variety of soils up to 500 or 600 feet. It is found even higher than this but does its best in the warm and dry lowlands if irrigated. There are many varieties, including some superb sorts of local origin as well as the renowned East Indian kinds and Cochin-China type. Of the Indian varieties, the Pirie gives most promise, but several others, as Mulgoa, Alphonse, Jemshedi and Brindabani, have done well. The Smith and the Wooten are two of the best of local origin. None of these better varieties is widely disseminated, partly on account of their recent introduction and partly because ready methods of rapid multiplication have not long been developed. For this reason, it is impossible to find any choice mangoes in the local markets, the few that are sold being disposed of privately at about 5 cents a fruit. This condition will not continue for many years, for the choice sorts are now being disseminated. The mango also is under quarantine on the mainland because of the Mediterranean fruit-fly, but the best varieties could be profitably grown for the local markets and for supplies to passenger ships. Certain fine varieties are quite resistant to the attacks of the fly.

1987. A banana plantation in the Hawaiian Islands.

Guavas (*Psidium Guajava*) cover the hillsides, the jungles in many places being composed chiefly or wholly of this tree. The wild fruit is gathered and used in the making of guava-jelly and jam, the greater part of which is consumed locally. A few selected varieties of this species and of the strawberry guava (*P. Cattleianum*) are cultivated in gardens.

The papaya (*Carica Papaya*) is the most important breakfast fruit in Hawaii and is grown in almost every dooryard as well as in small orchards. It is of very easy culture, coming into bearing within a year from planting and continuing for several years to produce good fruit on almost any well-drained soil. For this reason it is a fruit for the rich and the poor alike. The tree is propagated chiefly by seeds and as there has been very little attempt to keep strains pure, there is a very wide variation in flavor and other qualities. The difficulty of keeping pure strains has been complicated by the fact that most papayas are diœcious and it is impossible to know the inherent qualities of the male trees. But fortunately there is a hermaphrodite type and with this there is hope of establishing reasonably stable varieties of good quality.

A great variety of tropical and semi-tropical fruits and nuts is to be found in these islands. A list of some of the more important of these is as follows:

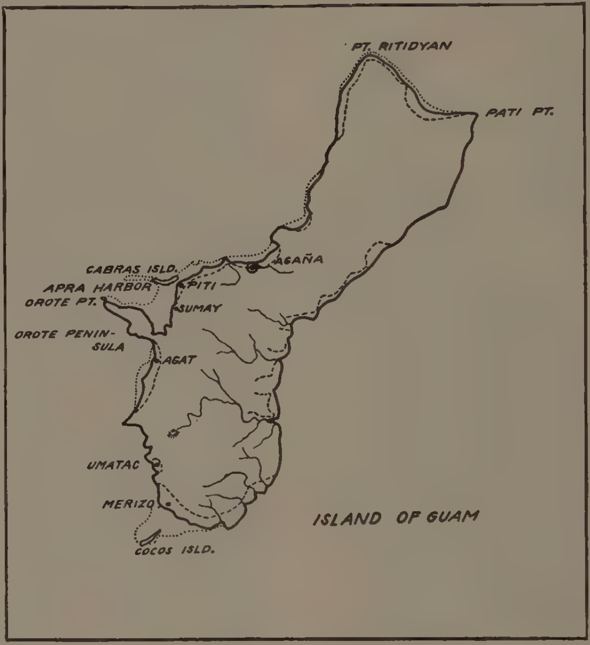
- Ananas sativus (pineapple).
- Artocarpus:
  - (*a*) Artocarpus incisa (bread-fruit).
  - (*b*) Artocarpus integrifolia (Jack-fruit).
- Annona:
  - (*a*) Annona muricata (soursop).
  - (*b*) Annona squamosa (sweet-sop or sugar-apple).
  - (*c*) Annona reticulata (custard-apple or bullock's heart).
  - (*d*) Annona Cherimola (cherimoya).
- Anacardium occidentale (cashew).
- Averrhoa Carambola (carambola).
- Ægle Marmelos (Bael fruit; elephant apple; or Bengal quince).
- Achras Sapota (sapodilla).
- Aleurites Moluccana (kukui nut).
- Areca Catechu (betelnut).
- Bunchosia sp.
- Citrus:
  - (*a*) Citrus sinensis (sweet orange).
  - (*b*) Citrus Aurantium var. Amara (sour or Seville orange).
  - (*c*) Citrus Limonia (lemon).
  - (*d*) Citrus sp. (rough lemon).
  - (*e*) Citrus aurantifolia (lime).
  - (*f*) Citrus grandis (pomelo or grapefruit).
  - (*g*) Citrus grandis (shaddock).
  - (*h*) Citrus nobilis (Mandarin orange).
  - (*i*) Citrus japonica ("China" orange, or kumquat).
  - (*j*) Citrus Medica var. genuina (citron).
  - (*k*) Citrus mitis (Calamondin orange).
- Canarium commune (pilinut).
- Carica:
  - (*a*) Carica Papaya (papaya).
  - (*b*) Carica quercifolia (dwarf papaya).
- Chrysophyllum Cainito (star-apple).
- Casimiroa edulis (white sapota).
- Coccoloba uvifera (shore-grape).
- Cocos nucifera (coconut).
- Cocos Gaertneri
- Claucena Lansium (the wampi).
- Diospyros decandra (Cochin-China persimmon).
- Durio zibethinus (durion).
- Eriobotrya japonica (loquat).
- Eugenia:
  - (*a*) Eugenia malaccensis (mountain apple).
  - (*b*) Eugenia Jambos (rose apple).
  - (*c*) Eugenia uniflora (Cayenne or Surinam cherry).
  - (*d*) Eugenia sp. (1, white water apple).
  - Eugenia sp. (2, red water apple).
  - (*e*) Eugenia myrtifolia (brush cherry).
  - (*f*) Eugenia Jambolana (black plum or jambolan plum).
- Ficus Carica.
- Garcinia:
  - (*a*) Garcinia Mangostana (mangosteen).
  - (*b*) Garcinia sp. (African mangosteen).
- Hibiscus Sabdariffa (roselle).
- Inocarpus edulis (mape, or Polynesian chestnut).
- Lucuma nervosa (egg-fruit).
- Malpighia glabra (Barbados cherry).
- Musa (banana):
  - (*a*) Musa Cavendishii (Chinese banana).
  - (*b*) Musa sapientum (including practically all other common edible bananas).
- Mangifera indica (mango).
- Mammea americana (mammee apple or St. Domingo apricot).
- Monstera deliciosa (delicious monster).
- Macadamia ternifolia (Australian nut).
- Morus alba (the mulberry).
- Morus nigra (the mulberry).
- Morus multicaulis (silkworm mulberry).
- Nephelium (genera Litchi and Euphoria):
  - (*a*) Nephelium Litchi (litchi).
  - (*b*) Nephelium Longana (longan).
- Noronhia emarginata.
- Olea europæa (olive).
- Persea gratissima (avocado).
- Passiflora (the passion flower fruits):
  - (*a*) Passiflora lauriflora (yellow water-lemon).
  - (*b*) Passiflora edulis (purple water-lemon).
  - (*c*) Passiflora quadrangularis (granadilla).
  - (*d*) Passiflora alata (granadilla).
- Psidium (guava).
  - (*a*) Psidium Guajava (sweet, sour, and lemon guavas).
  - (*b*) Psidium Cattleianum (strawberry guava).
- Phœnix dactylifera (dates).
- Punicum Granatum (pomegranate).
- Phyllanthus acida (Indian gooseberry).
- Phyllanthus Emblica (emblic myrobolan).
- Physalis peruviana (poha).
- Rubus Macraei (akala).
- Rubus hawaiiensis (Hawaiian wild raspberry).
- Spondias dulcis (Wii fruit, or Tahitian Vii apple).
- Terminalia Catappa ("Kamani" [foreign] tropical almond).
- Tamarindus indicus (tamarind).
- Theobroma Cacao (cacao).
- Vitis (grape: chiefly V. vinifera and V. labrusca).
- Vanilla planifolia (vanilla).
- Vaccinium reticulatum (ohelo).
- Zizyphus Jujuba (Jujube).

Vegetable-gardening is conducted chiefly by the Chinese and Japanese, who grow most of the more easily managed vegetables. Nearly all the vegetables found in the mainland markets can be grown in Hawaii, but some require special skill and a few demand an elevated location. All the cucurbits are difficult of culture except in isolated localities because of the prevalence of the melon fly (*Dacus cucurbitæ*), which also attacks less seriously tomatoes, peppers, and a few other vegetables. Sweet corn, peppers, and tomatoes were shipped experimentally to San Francisco as winter vegetables and realized good prices, but it was necessary to discontinue this trade because the melon fly had been found to some degree in each of these vegetables and is not known in California. Sweet potatoes, which are so easily grown here, have been shipped to San Francisco during the spring and early summer months, and early onions, chiefly of the Bermuda type. Both of these bring high prices, being easily grown in good quality for the opportune season in the market, and each may become the basis of a rather important trade if no insect or disease prevents its being shipped.

Taro (*Colocasia antiquorum* var. *esculentum*) furnishes the chief food of the native Hawaiians and is much used by foreigners also. It, therefore, requires a considerable area of land to supply the local market. There are many varieties of taro and some of the best succeed only under submerged conditions and for this reason, this crop, with rice, occupies most of the valley bottoms, where water can be led readily from the streams. Other varieties which succeed with less water are grown in moist lands where there is a heavy rainfall. Very few Hawaiians now engage in growing taro extensively, the industry being conducted chiefly by the Chinese. The plant has a large corm or rootstock and is propagated by cuttings from the top of this or of the smaller offsets. The crop matures in ten to fifteen months and the corm which is rich in a very easily digestible starch, furnishes most of the food, although the tender young leaves are also eaten. Taro is eaten as a vegetable and makes a good substitute for the potato, but its chief use is in the making of poi, the most important Hawaiian dish, which is prepared by crushing the steamed corm with stone pounders or more recently by American-made machinery. It is about the consistency of paste and is eaten after it has been allowed to ferment for a few days. Taro flour under various trade names has been placed upon the American markets.

Hawaii is a land of flowers, but many of the most beautiful blooms are on large trees and vines. Among the most striking of these are the royal poinciana (*Poinciana regia*), golden showers (*Cassia fistula*), pink showers (*Cassia grandis*), pink and white showers (*Cassia nodosa*), bougainvillæa, petrea, beaumontia, alamanda, bignonia, and plumeria. The night-blooming cereus flourishes and presents a magnificent sight when in flower. The old Hawaiian custom of bedecking guests at a feast or embarking friends at a departing vessel is still kept up, and it is one of the unique and beautiful scenes in Hawaii when a steamer engaged in the Honolulu-San Francisco run leaves the Hawaiian port, with all its passengers decorated with "leis" (pronounced lays) or wreaths of flowers. Until recent years, this constituted the chief market for cut-flowers. During the last eight or ten years a considerable cut-flower trade of the American type has grown up and there are several Americans now in the business and also a number of Japanese florists.

The city of Honolulu supports a number of small parks, containing some interesting and curious plants. In gardens, owned by private individuals, are many more rare and beautiful plants. The great Moanalua estate, the property of Samuel M. Damon, with its parks and gardens, is one of the most interesting places of Honolulu for the admirer of plants, and no plant-lover should pass by the islands without visiting these grounds, which are traversed by the public road and thus generously made available to all who are interested. Another strikingly beautiful sight which no one who is in Honolulu at the right time should fail to see, is the 1,000 feet or more of night-blooming cereus at the Oahu College grounds. The exact seasons of flowering are impossible to predict, but there is usually a grand display for several nights in May or June and again in August or September.



1988. The island of Guam.

Literature.—The literature of horticulture in Hawaii is limited. The only book devoted exclusively to the subject is "Fruits of the Hawaiian Islands," by G. P. Wilder, Hawaiian Gazette Company, Ltd., Honolulu. The bulletins and reports of the horticultural department of the Hawaii Experiment Station cover a part of the field and are as follows: "The Banana in Hawaii," Bulletin No. 7; "Citrus Fruits in Hawaii," Bulletin No. 9; "The Mango in Hawaii," Bulletin No. 12; "Marketing Hawaiian Fruits," Bulletin No. 14; "Shield-budding the Mango," Bulletin No. 20; "The Avocado in Hawaii," Bulletin No. 25; "Fruit-marketing Investigations in 1907," Press Bulletin No. 21; "Pineapple Shipping Experiments in 1908," Press Bulletin, No. 22; "The Pineapple in Hawaii," Press Bulletin No. 36; Annual Reports 1901 to date. See also "Index to Publications of the Hawaii Agricultural Experiment Station, July 1, 1901 to December 31, 1911." Numerous references to horticultural subjects are to be found in "The Hawaiian Forester and Agriculturist," the "Paradise of the Pacific," "The Mid-Pacific Magazine," and other periodicals.

J. E. Higgins.

Guam.

The island of Guam (Fig. 1988), belonging to the group of islands known as the Ladrones or Marianas, lies in the Pacific Ocean between the parallels 13° 14′ and 13° 40′ north of the equator, and between the meridians 144° 37′ and 144° 56′ east of Greenwich. A line drawn almost due west from Guam strikes, at a distance of about 1,200 miles, the San Bernardino Passage dividing the island of Samar from the southern extremity of Luzon and marks the relative position of Guam and the Philippine Archipelago. Of the fourteen islands composing the Mariana group, Guam is the largest and its position the most southerly. It is of historic interest as the first stopping place of Magellan after passing beyond the South American coast on that remarkable voyage of exploration for the Spanish crown in 1521. The island did not, however, assume a place of special interest in the minds of the American public until the year 1898 when, by the provisions of the treaty of Paris concluding peace between the United States and Spain, it became territory of the United States.

Guam has a warm and humid climate. The temperature is remarkably equable throughout the year; and no physical or other influences exist to cause perceptible variation in temperature in different parts of the island. Absolute temperatures seldom rise above 95° F. in the heat of the day or fall below 70° F. at night. The average annual rainfall is in the vicinity of 120 inches; and a very large percentage of the yearly precipitation occurs during the period from July to November inclusive. During the remainder of the year rainfall is erratic and uncertain. The climatic factor most potent in retarding horticultural progress is the occasional furious hurricanes or typhoons. These storms occur more or less frequently and sometimes with such sweeping force as to leave the island vegetation almost completely devastated of all its foliage.

The northern portion of the island is an inclined forest-covered plateau, rising from near sea-level at a point a short distance north of Agaña to an elevation of some 500 or 600 feet at the northern extremity of the island and to an almost equal elevation along the east coast. The soil of this plateau is of coral derivation and at many points is underlaid with partially disintegrated coral limestone covered at many points with but a few inches of soil. This territory is well drained and has a fertile soil usually well adapted to the cultivation of horticultural products. On it coffee grows luxuriantly and yields abundant crops of berries of a specially superior flavor. Cacao (*Theobroma Cacao*), producing the so-called chocolate bean of commerce, was grown in this district with much success prior to the severe typhoon that ruined the plantations in 1900. The lack of fresh water streams or other domestic water-supply prevents the rapid development of this district. The remaining portion of the island lying south of Agaña has a rolling contour and is traversed by numerous river valleys made fertile by sediment deposited from the surrounding hills. These valleys afford favorable conditions for the cultivation of coconuts and many of the tropical fruits. Constant and heavy rains during the period of excessive rainfall have leached the hill lands, rendering them of little value for horticultural purposes. The island's highest elevation is found in the peak "Humuyong Manglo," signifying "the mountain whence the winds issue." This peak is located in the southwestern part of the island and reaches an altitude of 1,274 feet. A strip of strand, varying in width but usually under a mile in extent, fringes a greater part of the coast-line. The soil of this low land has been formed partially from the washings and erosions from the surrounding hills and partially from shell, calcareous sands, and the like, of marine formation. Due to the fertility of this soil and to its proximity to the sea which furnishes fish and transportation facilities for the exchange of supplies between the different parts of the island, all the principal villages have been established here, and here also horticulture is more extensively practised than in any other part of the island.

The advantages of a well-defined economic system, involving the principles of labor-division as practised in modern enlightened communities, are unrecognized in Guam. In general, every man is his own fisherman, his own tradesman, and husbandman of the trees and plants required to feed his own family. The local market demands under such a system are decidedly limited; and the tendency is naturally in the direction of small plantings and indifference toward the improvement of varieties and methods of cultivation. There are neither nurseries nor seed farms on the island. Plants of the banana, pineapple, and the like, grow from suckers, but aside from those species which propagate naturally, the fruits trees are the simple result from chance seedlings voluntarily produced from discarded seed, with but little effort being made to foster or preserve them. The practice of perpetuating superior forms by the various methods of asexual propagation is unknown to the Guam planter.

Agricultural implements are of the crudest and most antiquated type. The native plow is an awkward home-made wooden contrivance with a single handle and a rough cast moldboard and point. It is drawn by a water buffalo and tears and thrusts aside the soil, leaving a ragged furrow about 4 inches wide. A man with a buffalo and one of these implements, working on an eight-hour-day basis, will require at least five days to plow in a most ineffectual manner 1 acre of land. In addition to the plow, a simple little hand tool, the fosiño, on the principle and of the construction of a scuffle-hoe, is the only implement in common use for tilling the soil.

Regardless, however, of the primitive methods of the people, Guam is essentially a land of agriculture. It has no other possible natural resource. With a moderately fertile soil and a climate permitting the planting and harvesting of crops during 365 days of the year, the island is a garden specially created for the farmer. How rapidly the development of the agricultural industries may come, or how remote the time when the full possibilities of the island may be achieved, is a matter of mere conjecture, but the absolute necessity of improvement is daily becoming more manifest. Education is rapidly creating a higher and more expensive standard of living and this increased expense must be balanced by correspondingly augmented production from the soil. Lack of shipping facilities has seriously impeded progress in horticultural lines and until improvement is brought about there is little to encourage the establishment of the fresh fruit industry upon a commercial basis. Products for export must necessarily be limited to such of the less perishable crops as coconuts, coffee, and cacao, and to articles preserved by some of the various methods, of which pickling, bottling, canning, and evaporation are examples.

The coconut (*Cocos nucifera*) was found growing in Guam at the time of the discovery by the Spaniards. Safford observes that "the first accurate description of the coconut was published by Dampier from observations made by him in Guam in 1686." This is the most important product of the island, copra, the dried kernel of the nut from which the coconut-oil of commerce is expressed, constituting the only article of export. The nut is also variously used in cookery, and furnishes one of the principal feeds for both poultry and hogs. Aside from the nut itself, the leaf is split through the midrib from the terminal end and the pinnæ of each plaited together, forming from each frond two crude but effective shingles for thatching the roofs of buildings. The fact that probably 95 per cent of the dwellings in Guam are thatched with this material indicates the extent to which the leaves are used for this purpose. Toddy, a popular beverage, non-intoxicating when first drawn, is collected from an incision in the flower-stalk; and this, by the process of boiling, is converted into syrup, and, by a further continuation of the process, sugar is obtained. Fermented toddy is an intoxicant and is extensively employed in lieu of yeast in making bread. It is also used in the preparation of vinegar or, by distillation, a highly alcoholic liquor, known as "aguardiente," is produced.

The native devotes but little attention to his trees; yet natural conditions are favorable, and the trees flourish and yield good crops regardless of neglect. Bud-rot has not made its appearance on the island. Cattle running at large cropping off the young trees, and rats which gnaw off the young immature nuts, are, as a matter of fact, the only serious enemies of the plantation. In Guam, crops are gathered to a limited extent during all seasons of the year, but the general tendency is to confine pickings as much as possible to the dry season, when weather conditions facilitating the process of air-drying the copra usually prevail. Drying with artificial heat is never practised. That part of the output going to the export trade is disposed of to Japanese traders who ship by sailing schooners to Yokohama where the oil is expressed and the residual meal employed to increase fertility of Japanese gardens. To give some idea of the importance of the industry, the following custom-house records covering the exports for the annual periods ending June 30, for the past three years are given:

Period	Tons	Value
1909–10	534.5	$33,610.11
1910–11	870.5	51,058.80
1911–12	1047.0	59,924.10

Fruit of bananas and plantains, Musa species, grow in rich profusion everywhere and form an important food staple of the people. Plantations are not established systematically and are confined to small areas of land contiguous to the home. Total neglect of the plantation is common and when cultivation is at all practised it consists of the occasional removal of weeds and grasses and the application of this organic matter and a small amount of surface soil about the base of the plants. This mulch of soil and litter serves two purposes, according to the season of its application. In hot dry weather it cools the soil and assists in the conservation of moisture, and in the season of heavy rainfall its rapid decomposition adds fertility to the root-feeding areas of the soil.

Among the forms common in Guam, the Chinese dwarf or Cavendish banana (*Musa Cavendishii*), known in the vernacular of Guam as chotda Guahu (the Oahu banana), is the only well-known commercial variety. It is of comparatively recent introduction and is not well distributed. Chotda Dedos (the finger banana) is so named from the long slender form of the fruit, lending a fancied resemblance to the fingers on a human hand. Chotda Haya (pronounced hadya—signifying native or unintroduced banana) is supposed to have been the earliest form cultivated on the island. Chotda Dama is similar and possibly identical to the variety "Gloria" of the Philippines, which Blanco refers to *M. paradisiaca ternatensis.* Chotda Manila (*M. paradisiaca cinerea*) has been introduced from the Philippines, where it is known as Letondal or Latendan. This variety, though inferior in flavor and subject to cracking and dropping from the bunch when ripe, is a heavy-yielding sort and consequently a most popular one. Probably 75 per cent of the bananas annually produced on the island are of this variety. Chotda tanduque (*M. paradisiaca magna*), a favorite fruit of the plantain type, eaten both cooked and uncooked, is also of Philippine introduction. Other good varieties of recent introduction which may be expected to assume leading places in the future are, the Bungulan (*M. paradisiaca suaveolens*), the Lacatan (*M. paradisiaca lacatan*), from the Philippines, and the Brazilian banana from the Hawaiian Islands. The Jamaica or Bluefields banana was introduced into Guam during the fiscal year 1912 by the United States Department of Agriculture.

1989. A native hut in Guam; roof thatched with coconut leaves. Sour-sop (Annona muricata) in left foreground

The leaves and false stem of the banana are relished by cattle and after maturing their fruit these constitute a valuable by-product.

Breadfruit (*Artocarpus incisa*) grows in great luxuriance in the warm humid climate of Guam, and it is probably nowhere more abundant or more highly esteemed. Uncultivated and uncared for, the copious supply of nutritious food which it yields during its long fruiting season from June to December is wholly a gift of Nature. Both the seed-bearing variety and the more highly improved seedless form of *A. incisa* exist in extensive forests. The breadfruit is not a commercial article, yet the important part which it plays in the domestic economy of the people renders it worthy of mention in a work of this character. In addition to the value of the fruit for human food, the immature fruits are fed to cattle and hogs and the ripe fruit also constitutes a most valuable hog-feed. The leaves of the breadfruit tree are largely employed as a fodder for cattle and the fondness shown for them by the native cattle is not acquired; for cows imported from the United States manifest an equal relish for them at the first feeding. In this connection the necessity of providing the young plants with protection from cattle is indicated.

The coffee shrub (*Coffea arabica*), and to a more limited extent the Liberian species (*C. liberica*), are successfully grown, and especially is this true in the district of Yigo in the northern part of the island and at Sinahaña situated on an elevation south of Agana. It is said that during the latter part of the Spanish régime when direct shipping means existed between Guam and Manila, an export trade of considerable importance was enjoyed and that the Guam product was recognized for its superior quality. Coffee is now more sparingly grown than in former times and within the past few years the output has not been sufficient to supply the home demand. The absence from Guam of the coffee fungus, *Hemileia vastatrix*, so widely distributed throughout the Old World Tropics and so destructive to the coffee industry wherever it exists is both interesting and significant. Aside from field-rats, which feed upon the sweet pulp, dropping the naked berry to the ground, there are no serious pests to contend with in Guam. Even with the limited acreage adaptable to coffee-culture, the industry is entirely capable of development to the extent of not only supplying the home demand but also of furnishing a considerable surplus for export.

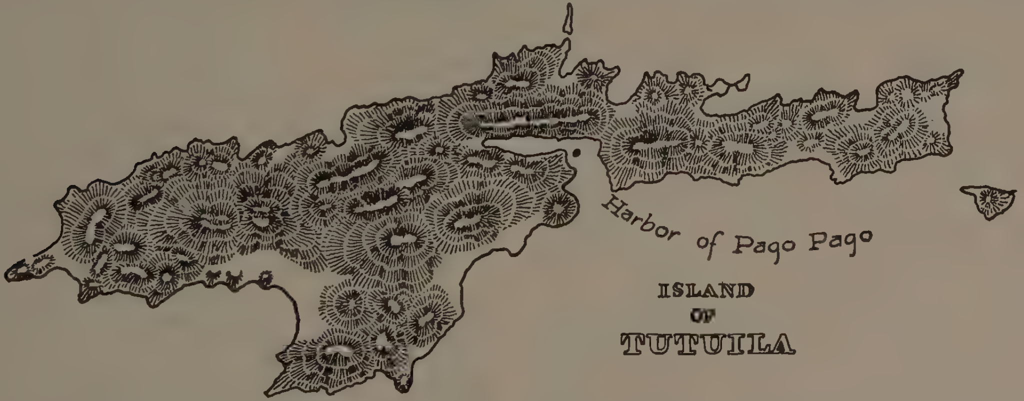
The mango (*Mangifera indica*), a most delicious tropical fruit, is grown in Guam in two races, both of which come true to seed, or at least practically so, and are propagated only by that method. The "Guam mango" is of medium size, contains but little fiber and is free from the disagreeable taste of turpentine, common to some of the inferior varieties, when it is properly ripened. It is identical with the common "Carabao" mango of the Philippines. In the quality of its fruit this variety is superior, but on the island of Guam it possesses the disadvantages of light and irregular bearing-habits. Another feature in the cultivation of this species that tends to discourage planting is the fact that trees require from twelve to twenty years to grow from the seed to a state of production. Owing to these habits of slow development and light yields, the supply of mangoes is insufficient to meet the demand for them and the same conditions create an ever-ready market-price of 5 to 10 cents United States currency for a fruit. Large trees claimed to be more than 100 years old, measuring as much as 9 feet in circumference of the trunk and from 50 to 60 feet in top diameter, are common.

The "Saipan mango" introduced from the island of that name, now seat of the German government in the Marianas, is a small fruit weighing about four ounces. It is full of a coarse fiber and is inferior in flavor. The tree of this variety is of comparatively small dimensions, comes into bearing in four to seven years from the seed, and is a regular and heavy bearer. As a fruit this race is of little importance, but as a stock upon which to inarch the "Guam mango" it should prove valuable, as its less vigorous root-system should result in dwarfing the tree of the Guam variety and in rendering it more prolific.

In addition to the more important fruits noted above, others of more or less value abound in great variety. Lemons and limes of fair quality and oranges of an inferior grade are plentiful. The bullock's-heart (*Annona reticulata*) grows spontaneously, and the sour-sop (*A. muricata*) and sweet-sop (*A. squamosa*) are common fruits. The papaya (*Carica Papaya*), in a degenerate form, has escaped from cultivation and grows in great profusion throughout the island. Excellent papayas are grown from introduced seed of improved forms, but hybridization between these and the native papayas results in a reduction in the size of the fruit with each successive generation. When careful methods of hand pollination are not practised, the use of introduced seeds of the best improved varieties is found essential to best results. The avocado (*Persea gratissima*) has been introduced since the establishment of American government on the island and the remarkable vigor and heavy yields of a few trees indicate a bright future for this new fruit. Pineapples, small in size and of fair quality, are found in neglected plantings. The United States Department of Agriculture has introduced plants of the Smooth Cayenne pineapple, which promises great improvement over the native variety. The sapodilla (*Achras Sapota*), the cashew (*Anacardium occidentale*), the carambola (*Averrhoa Carambola*), the Otaheite apple (*Eugenia malaccensis*), the guava (*Psidium Guajava*), and the tamarind (*Tamarindus indica*), are all listed in the catalogue of island fruits.

A discussion on vegetable-gardening in Guam must essentially treat of possibilities rather than of achievements. Gardening is practised to a very limited extent and in accordance with the most antiquated methods. Among the most common temperate-zone vegetables, tomatoes, potatoes, cabbage, sweet corn, and garden peas are not successful. Beans in wide variety of types, radishes, lettuce, okra, eggplants, peppers, cucumbers, muskmelons, and watermelons are all successfully produced. Important rootcrops, handled more as field than garden products, are yams, taro, and sweet potatoes. The most important food staple cultivated on the island is maize. Rice was formerly grown extensively, but now nearly all the rice consumed on the island is imported. Tobacco is also successfully cultivated by the natives. Peanuts are common and are grown entirely from vine cuttings. The difficulty of preserving the vitality of many of the common garden seeds in the warm humid climate of Guam is one of the principal causes of the present indifferent attitude shown by the native farmer toward the cultivation of the vegetable-garden.

A few species of valuable tropical hardwoods are found in the forests of Guam but owing to extravagant and wasteful cuttings, the better grades of timber are becoming comparatively scarce. Among the most important of these species, *Afzelia bijuga*, known in Guam as "ifit," is extensively used for general construction purposes and as a cabinet-wood. *Calophyllum inophyllum*, generally designated as "palo maria," is usually employed in cabinet-work and the construction of cart wheels. *Claoxylon marianum*, the "panao" of the Chamorro, is specially valued for flooring purposes. *Heritiera littoralis*, called "ufa," is utilized in making plow-beams, while *Ochrocarpos obovalis* and *Premna Gaudichaudii*, known respectively as "chopag" and "ahgao" are extensively employed in the construction of buildings.



1990. Tutuila.

A systematic flora of the island has recently been published by E. D. Merrill ("An Enumeration of the Plants of Guam," Philippine Journ. Science, Vol. IX, 1914). Merrill points out the affinity of the Guam flora with that of the Malayan region, practically all the indigenous genera being of wide Indo-Malayan distribution. The nearest approach to an endemic genus is Saffordiella, which also is found on the island of Yap. Among the new orchids described by Ames are species of Bulbophyllum, Liparis, Eulophia, Phrætia, Cœlogyne, Saccolobium, and Dendrobium. Among the conspicuous forest trees, Merrill describes several banyans, the sacred nunus of the natives, *Ficus mariannensis* and *F. Saffordii;* the yoga, *Elæocarpus joga*, a lofty tree with buttressed trunk and clusters of bluish grape-like fruit; a new almendra, or talisai, *Terminalia Saffordii*, with edible almond-like fruit; and several species of Eugenia. He also describes several new shrubs, among them, *Macaranga Thompsonii* and *Phyllanthus Saffordii*, belonging to the Euphorbiaceæ; *Grewia mariannensis*, closely allied to the Polynesian *G. malococca;* a number of Rubiaceæ, including species of Hedyotis, Morinda, Oldenlandia, Psychotria, and Tarenna; and *Discocalyx megacarpa*, a plant with erect habit, glossy green leaves, and bright red berries.

For further information on the horticulture of Guam, see "The Useful Plants of Guam," by Safford, and the Annual Reports of the Guam Agricultural Experiment Station.

J. B. Thompson.

Tutuila.

The most important island of American Samoa (Fig. 1990) is situated about 4,200 miles southwest of San Francisco in latitude 14° 20′ south and longitude about 170° 40′ west of Greenwich. Although smaller than the German islands, Savaii and Upolu, lying to the westward, it is more important strategically on account of its remarkable natural land-locked harbor, Pago-Pago, the precipitous walls of which afford safety to an entire squadron even during the violent hurricanes which sometimes sweep the group. Tutuila has an area of about 54 square miles, with a population of nearly 4,000 inhabitants. Like other islands of the group, it is volcanic with barrier coral reefs surrounding it. The forest-clad mountains rise to a height of about 3,000 feet. Several other neighboring islands belonging to the United States have a combined area of not more than 25 square miles and a population of 2,000 inhabitants. The group known as Manua, lying a degree to the eastward of Tutuila, is composed of the small islands Tau, Ofu, and Olosenga, the first formed like a great mole-hill, the other two rising precipitously from the sea. Rose Island, lying 70 miles to the eastward, is a typical coral atoll almost circular in shape.

The islands are swept almost continually by the trade-winds, and there is abundant rainfall. The climate is healthful, the volcanic soil quickly arbsorbing the precipitated moisture. December, the warmest month, has a mean temperature of about 87° F.; July, the coolest month, a mean temperature of about 78° F.

American Samoa is governed by an officer of the United States Navy, detailed by the Secretary of the Navy. The wisdom of the government in dealing with the natives is shown by its methods of administration. Ancient Samoan customs are followed as closely as possible. The villages choose their own chiefs from those who have hereditary rights to the position, subject to the governor's approval. The villages are grouped into counties ruled by high chiefs and the counties are grouped into three great districts, Eastern Tutuila, Western Tutuila, and the District of Manu'a, each of which has at its head a chief appointed by the governor. The customs officer is a naval officer and the health department is under a medical officer of the Navy, who has charge of the island dispensary and the hospital, or sick quarters, of the station. At the end of each year there is held a general fono, or assembly to which all parts of the islands send delegates. In this assembly matters of general interest are discussed, new laws recommended, complaints and suggestions are listened to, laws are explained, and information given regarding all matters affecting the welfare of the natives and the administration. Suffrage is restricted to the heads of families (matais) in accordance with Samoan custom, the family and not the individual being considered the unit of society.

1991. Samoan dwelling thatched with sugar-cane leaves, with side blinds of coconut-leaf mats, on the sloping shore of Pago-Pago Bay, Island of Tutuila. Surrounding vegetation: bananas, coconut palms, breadfruit tree, and 'ava pepper (Piper methysticum), a large mango tree in the distance.

There are no public lands in American Samoa. Even the land occupied by the Naval Station was acquired from the native owners by purchase. A few small tracts are owned by foreigners, who acquired their titles before the American occupation. Only one plantation is owned by a white man, and he is connected by marriage with one of the highest chiefs of Samoa. On his plantation in a valley on the north side of Tutuila, he has planted coconut trees, rubber, cacao, and a small amount of coffee. On account of the small amount of arable land there is no opportunity for Americans to become planters in these islands.

The only product of commercial importance is copra, the dried meat of the coconut. All the beaches are fringed with coconut palms. At the mouths of streams where the water is brackish, there are mangrove thickets composed chiefly of Rhizophora and Bruguiera. Surrounding the thatched huts of the natives are many ornamental plants, including *Hibiscus rosa-sinensis*, the beloved aute of the natives, who adorn themselves with its bright red flowers; trees of the fragrant *Canangium odoratum*, here called "moso'oi," from the flowers of which the natives make garlands and prepare a scented oil for anointing their bodies; clumps of pandanus, from the leaves of which they weave their mats; ironwood (*Casuarina equisetifolia*) called "toa," from the trunks of which they make spears and war-clubs; *Piper methysticum* from the roots of which they prepare their national drink called "'ava;" and nearby are usually clumps of bananas and plantains; patches of taro (*Colocasia antiquorum* var. *esculenta*) the starchy roots of which form one of their most important food staples; trees of breadfruit (*Artocarpus incisa*) magnificent mango trees; the Polynesian "chestnut" (*Inocarpus edulis*), called "ifi;" several varieties of yams (Dioscoreæ) the paper mulberry (*Broussonetia papyrifera*), from the inner bark of which the women make bark-cloth, the widely spread *Hibiscus tiliaceus*, here called "fau," from the bark of which they make cordage; urticaceous plants, fau-songa (*Pipturus argenteus*) and fau-pata (*Cypholophus macrocephalus*), from the fiber of which they make their shaggy mats and their fishing nets; dracæna-like *Cordyline terminalis*, here called "ti," from the leaves of which they make skirts worn while fishing on the reef; besides many other interesting and useful plants.

Though much of the island is too steep for cultivation, every foot of the soil near the coast seems to yield useful plant products, and edible sea-weeds are secured from the shallow lagoons between the shore and the surrounding reefs.

The slopes of the mountains as well as the valleys are covered with rich humus formed principally by the decay of vegetable matter together with a slight proportion of decomposed volcanic rock. Nearly all tropical plants which have been tried have been grown successfully. Oranges, grapefruit, lemons, limes, citrons, the mango, alligator pear (aguacate, or avocado), papaya, pineapple, are among the introduced fruits. The citrous fruits are subject to scale. The lemons are mostly thick-skinned and of inferior quality. Bananas of many varieties are cultivated, each family having a banana-patch for its own use. Certain varieties are allowed to ripen and eaten raw, while others are gathered immature, before the starch has turned to sugar, and are cooked as a vegetable. The varieties growing in Samoa before its discovery are known as "fa'i Samoa," while those introduced by the whites are called "fa'i papalangi." Banana leaves are used for table-cloths, umbrellas, wrapping-paper (with the mid-rib removed), improvised hats (when it rains), and, when dried, for cigarette wrappers. In addition to the cultivated species there is a wild banana in the mountains, called "soa'a" (*Musa Fe’i*, Bart.), which yields a black dye. Of this species which bears its fruit in an erect raceme, the natives have a story telling of a battle between the soa'a and the fa'i. The soa'a was victorious and ever since it has kept its head erect, while the conquered fa'i is compelled to bow its head earthward as a token of its humiliation.

Several varieties of taro (*Colocasia antiquorum* var. *esculenta*) are cultivated, some of them in marshy places, others in clearings made in the forest. On the island of Tutuila there is not much marsh taro in comparison with upland taro. The latter is usually planted in virgin soil in holes made by a digging-stick. Very little care is afterward bestowed upon it except to keep the patches weeded. Marsh taro requires a constant supply of fresh water. The starchy roots must be thoroughly baked to destroy their acridity, which, like that of our Indian turnip, is caused by minute needles of oxalate of calcium (raphides). Closely allied to the taro is the giant taro, *Alocasia macrorhiza*, called "ta' amu" by the Samoans. Several kinds of ta'amu occur in Samoa, all of which are probably varieties of *A. macrorhiza*. They are propagated like upland taro. The roots, which sometimes reach a great size, in times of scarcity are an important food staple. The enormous satiny leaves are used for covering the native ovens. The young leaves of taro are cooked in various ways as a vegetable. One of the most agreeable dishes, called "palusami," is composed of the expressed cream of grated coconut meat combined with young taro leaves and a little salt water wrapped in an outer covering of leaves and baked in a native oven. The fermented paste made from taro known in the Hawaiian Islands as "poi" is unknown in Samoa.

Yams (*Dioscorea Batatas*), called "ufi" by the Samoans, resemble the forms known on the island of Guam as "dago." The tubers often grow to an enormous size. The plants are propagated by cuttings, each of which must possess an eye or bud from which the new plant springs. The plantations are made in clearings in the woods, stones are laid around the young plants and stakes are placed for the plants to climb upon. In about six months after planting the tubers are ready for food. As the propagation and gathering of yams are more difficult than in the case of taro, they are not so extensively grown, though they thrive well and are well liked by the natives.

Tacca pinnatifida, Forst., called "masoa" by the Samoans and commonly known as "Polynesian arrowroot," yields an excellent starch, which is used principally for pasting together the filmy beaten bast of the paper mulberry in making bark-cloth (siapo). It is also an article of food and is sometimes prepared with coconut custard in the form of dumplings or puddings. In Tahiti the natives braid beautiful hats from the epidermis of the flower-scapes and petioles of this plant. As with the yams, the tubers are mature when the plants die down. When fresh they are bitter. The starch is prepared by grating the tubers to a fine pulp which is put into a vessel of water. This becomes milky and the solid particles are removed by straining. After standing for some time, the starch settles and the clear liquid is poured off. This plant grows spontaneously in Samoa, but it is sometimes cultivated.

Rice is not cultivated. Though it was introduced into the island of Guam before the discovery of that island by Europeans, it was entirely unknown to the ancient Polynesians of the central and eastern Pacific.

The breadfruit (*Artocarpus incisa*) is planted about every village. It grows in the form of a symmetrical tree with spreading top. Its curved limbs furnish the Samoans with rafters for the roofs of their best houses; the viscid milky latex is used by them for many purposes; and the large lobed leaves are eaten with relish by all herbivorous animals. The fruit, gathered before it is quite ripe, is prepared for food in a variety of ways. It is often eaten with pork, fish, or fowl, sometimes with a sauce of cooked custard expressed from grated coconut meat; or in the form of dumplings cooked in this custard. As the breadfruit season is limited, quantities of the fruit are placed in pits and allowed to ferment, somewhat after the manner of sauer-kraut. Though the fermented substance has a very offensive smell, it is nutritious, and is made into cakes and baked. "Masi," the name of these cakes, is now a general term applied to all kinds of biscuits and crackers. The trees are propagated from suckers, to which a portion of a root of the parent plant is left attached. The young trees grow rapidly and in three or four years bear fruit.

The Polynesian "chestnut" (*Inocarpus edulis*) is a magnificent forest tree belonging to the Leguminosæ. Its fruit roasted in the shell has somewhat the taste of chestnuts and is much eaten by the Samoans. Its wood is hard and durable, of fine texture and very tough. It has the remarkable quality of burning readily while green.

Sugar-cane is grown to some extent. It has been grown by the Samoans from prehistoric times, but not for commercial purposes. No sugar is made on the island. The cane is relished especially by the children, who suck its sweet juice. Its principal use is in furnishing an excellent durable thatch for the houses of the natives.

Tobacco is grown in small quantities very much after the fashion pursued in other countries, first in seed-beds, then transplanted. It is consumed by the natives, both male and female, in the form of cigarettes wrapped with dry banana leaves.

Piper methysticum, called "kava" in some parts of Polynesia and "'ava" in Samoa, is extensively grown for the sake of the narcotic infusion prepared from its root. This is prepared with great ceremony in the presence of the chief or head of a family by young girls. In former times, the root was first chewed and then placed in the wooden bowl in the form of quids upon which cold water was poured from a coconut water-bottle; but now the root is rasped on an improvised grater made by puncturing holes in a sheet of tin. The infusion is not allowed to ferment but is drunk fresh, each person present partaking of it in succession in the order of his rank. 'Ava-drinking in Samoa is never indulged in so extensively as to become a vice, but the beverage is a wholesome and refreshing stimulant. 'Ava takes the place in Samoa of the betel pepper (*Piper Betel*) of the Philippines and the island of Guam, the leaves of which are chewed with areca nut and a little lime. The latter has never found its way into eastern Polynesia.

In the woods there are valuable hardwood trees, many of which are clothed with epiphytal orchids, lycopods, and ferns, and the slopes of the mountains yield rich returns to the botanist in rare ferns and other plants, especially graceful tree-ferns.

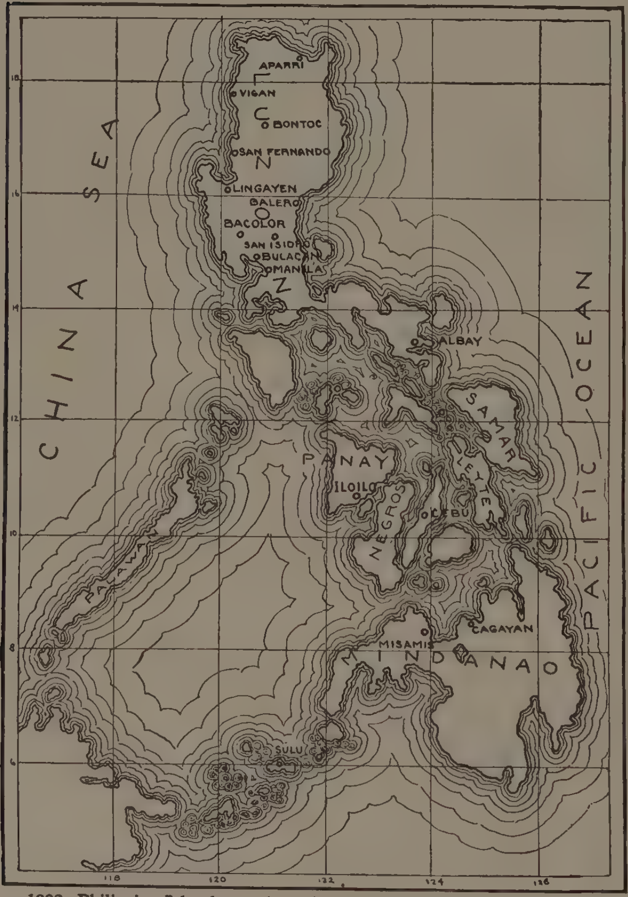
In the vicinity of Pago-Pago the most common trees are the fau (*Hibiscus tiliaceus*); milo (*Thespesia populnea*); lama, or candle-nut (*Aleurites moluccana*) called "kukui" in the Hawaiian Islands; toi (*Alphitonia excelsa*); tavai (*Rhus simarubæfolia*); masame (*Antidesma sphærocarpum*); tamanu, a species of Maba; and fetau (*Calophyllum inophyllum*). The futu (*Barringtonia speciosa*), a beautiful tree with glossy leaves and white flowers with crimson stamens, bears a peculiar four-angled fruit which is used in Samoa, as in Guam, for stupefying fish in tide pools on the coral reefs. The appearance of the red blossoms (aloalo) of the ngatæ (*Erythrina indica*) marks an epoch in the Samoan calendar. The ifilele, which is identical with the valuable ipil of Guam (*Intsia bijuga*), is prized for its durable hard wood, and is much used for house posts. The fragrant flowers of the langaali (*Aglaia edulis*), like those of *Canangium odoratum*, are used to scent the coconut-oil with which the natives anoint themselves. The fruit of the vi (*Spondias dulcis*) is highly prized by the natives and that of the nonu-fiafia (*Eugenia malaccensis*) is also eaten. The giant banyans (Ficus sp.), rising like great hillocks above the general level of the forests and remarkable for their numerous aërial prop-like roots, are regarded by the Samoans to be the dwellings of spirits (*aitu*). The Samoans have legends and songs regarding many of their forest trees and shrubs, one of which called "The Battle between the Trees and Stones" is translated by Augustin Kraemer in his monumental work, "Die Samoa-Inseln" (Vol. I, p. 361, 1902), to which the reader is referred. See also "American Samoa," a general report by Governor W. M. Crose, dated June 22, 1912, Washington 1913; and F. Reinecke's "Flora der Samoa-Inseln," Engl. Bot. Jahrb., Vols. 23 and 25, 1897, 1898.

W. E. Safford.

Philippine Islands.

The Philippines (Fig. 1992), lying between the Pacific and the China Sea, extend almost due north and south from Formosa to Borneo and the Moluccas, and cover about 700 miles of longitude and 1,000 miles of latitude (from 4.40° to 20° north latitude, and 116.40° to 126.30° east longitude). The archipelago comprises 3,141 islands, having a total area of 127,853 square miles, and has a population of above 8,000,000 inhabitants. The largest islands are Luzon, with an area of 40,969 and Mindanao with 36,292 square miles.

The Philippines are of volcanic origin and in consequence the topography of the archipelago is characterized by a broken surface and more or less rugged mountains in all islands of any importance. Between the mountain ranges and on the banks of some of the largest rivers lie several rich, level valleys awaiting the advent of the cultivator, areas which are eminently suited for the cultivation of rice, corn, sugar, tobacco, hemp, and coconuts. The principal plains are found in Isabela and Cagayan Provinces, watered by the Cagayan River; in Tarlac and Pangasinan, watered by the Agno; and in Nueva Ecija and Pampanga, through which flows the Pampanga. The Cottabato Valley in the Moro Province is irrigated by the Mindanao River. The interior of Mindanao, from the mountain ranges east of the Agusan River to Lake Lanao in the west, consists of a remarkable series of level tablelands of great fertility between the mountains and cañons at an elevation ranging from 1,000 to here and there exceeding 2,500 feet.



1992. Philippine Islands, to show the general form of the archipelago.

The climate is remarkably mild and free from extremes, though there is considerable variation in temperature due to altitude. The Weather Bureau of the Philippines distinguishes three types of climate peculiar to the Philippines: (1) That of Sorsogon, Albay, Ambos Camarines, Catanduanes, and adjacent islands, the eastern coast of Luzon from the seashore to the mountains in Tayabas, eastern Isabela, and Cagayan, the north and east coast of Samar, the east and north coast of Mindanao and adjacent islands, the valley of the Agusan River, and the east coast of Leyte; this climate is characterized by an average rainfall of 3,090 millimeters, well distributed throughout the year, mean temperature 79.8° F., lowest recorded temperature, 62.4° F., highest 110.3° F., the greatest rainfall being in December, and the least in May, June, and July. (2) That of the provinces of Batangas, Bataan, Ilocos Norte, Ilocos Sur, Zambales, Union, Rizal, Western Bulacan, Pampanga, Nueva Ecija, Tarlac, Pangasinan, the west coast of Panay, Mindoro and Mindanao, with an average rainfall of 2,120 millimeters, falling mainly from May to October with a distinctly dry season during December, January, February, March and April; mean temperature 80.5° F., highest recorded temperature 103.1° F., lowest 57.7° F. (3) That of the extreme north of Luzon, including the Cagayan Valley and the Batanes Islands, the shores of Laguna de Bay, the west coasts of Samar, and Leyte, the north and east coasts of Panay, Negros, Cebu and Bohol, Davao Gulf and the south end of the Zamboanga Peninsula; annual rainfall 1,882 millimeters, falling mainly from September to January, with a short dry season in February, March, and April, mean temperature 79.7° F., highest recorded temperature 100° F., lowest, 59.9° F.

The following export statistics for the years 1897 and 1911 illustrate the development of the plant industries in the Philippines during the last fourteen years:

1897

Manila hemp	$8,571,850
Sugar	6,911,535
Copra and coconuts	2,687,978
Tobacco products	2,128,380
Indigo	72,379
Coffee	45,648
Candlenut products	35,219
Ilang-ilang oil	24,937
Sappan wood	23,323
Copal	22,562
Maguey fiber	13,687
Fruits	8,393

1911

Manila hemp	$16,141,340
Copra	9,899,457
Sugar	8,014,360
Tobacco products	3,605,567
Bamboo hats	301,141
Maguey fiber	254,053
Copal	49,716
Ilang-ilang oil	47,404
Gutta-percha	41,065
Fruits and nuts	23,568
Sappan wood	16,220
Kapok cotton	11,324
Coffee	366
Cacao	199

By comparing these statistics it will be seen that the exportation of hemp has about doubled during this period; copra has leaped into second place instead of sugar, of which there has been a comparatively small increase; the production of maguey fiber has increased over twenty-fold.

Rice, of which there are about 1,000 varieties more or less, is the most important cereal in the Philippines. The principal rice-producing provinces are, in the order of their importance, Pangasinan, Nueva Ecija, Tarlac, Ilocos Norte, Bulacan, Pampanga, and Capiz.

Corn succeeds well, but is of comparatively limited cultivation, Cebu and Pangasinan being the chief producers; however, corn-growing is greatly on the increase. Mungos and cowpeas are the only legumes grown under field-culture, but are not cultivated extensively.

Manila hemp is the leading export article; it is obtained from the leaf-stems or petioles of the abacá (*Musa textilis*), and is grown principally in Albay, Leyte, Ambos Camarines, Sorsogon and Samar.

Copra is the next important export. Tayabas, Laguna, Albay, Samar, Moro, Cebu, Capiz, and Leyte are the source of most of the copra, and the culture of the coconut is on a steady increase.

Sugar, the fourth most important crop, is cultivated primarily in the Provinces of Occidental Negros, Pampanga, Batangas, and Iloilo.

Most of the tobacco is grown in Isabela, Cagayan, Cebu, La Union and Pangasinan.

The statistics below relate to the six principal crops of the Philippines for the fiscal year 1911.

Crop	Area Hectares	Product	Amount produced	Approximate total value in provincial markets
Rice..........	1,043,757	Cleaned rice	574,842,682 kilos	$32,995,940
Abaca.........	404,160	Manila hemp	171,879,598 kilos	13,750,367
Coconuts......	208,476	....	....	....
Average of 200 trees per hectare	....	Ripe nuts for food	154,980,726 nuts	13,130,636
		Copra	118,323,114 kilos	
		Coconut oil	6,602,966 liters	
		Palm wine	37,649,880 liters	
Sugar-cane.....	120,313	Crude sugar	243,924,574 kilos	12,196,238
Corn..........	302,516	Shelled corn	186,404,700 liters	4,361,869
Tobacco.......	69,015	Leaf tobacco	25,518,132 kilos	3,444,947

Both fruit- and vegetable-culture have been greatly neglected in the Philippines, notwithstanding the fact that the soil is almost everywhere of great fertility and that a great number of vegetables succeed well and produce abundantly when properly cared for.

Coconuts, with the steady and increasing demand for copra and other coconut products, are undoubtedly destined to become not only the chief horticultural industry in the Philippines but the leading industry in the archipelago. If a coconut plantation is well located and intelligently cared for there is probably no other enterprise in the Philippines today that offers so large a return with so little care and expenditure. (See Philippine Bureau of Agriculture, Bulletin No. 17.)

Coffee (*Coffea arabica*) was a very profitable crop until the entrance of the coffee blight (*Hemileia vastatrix*) about twenty-five years ago, which gradually destroyed the hitherto very profitable coffee-plantations. Coffee-culture is now of little or no importance, and coffee to the value of $255,039 was imported in the fiscal year ending 1911. *Coffea liberica*, *C. robusta*, and the Maragogipe hybrid have been introduced in order to revive the coffee industry, but without avail. From the present outlook, coffee-growing will never become an important industry until a blight-resistant variety shall have been found that is equal in quality to the Arabian coffee.

The cacao (*Theobroma Cacao*) was long ago introduced into the Philippines, and large areas are well adapted to the culture of this tree, particularly in Mindanao, but although found in all provinces, even the home demand for cacao has never been supplied, and the cacao products imported into the Philippines in 1911 amounted to $261,935. The reasons for this neglect of what would undoubtedly be a profitable industry are that hemp, coconuts and sugar-cane, which require less attention and care, yet yield profitable returns, have been more than the cacao adapted to the agricultural educational standard so far attained by the population in the Philippines. It should not be forgotton, however, that systematic cacao-culture has never been introduced, either by the Spaniards, or by the Americans after their occupation of the archipelago. It cannot be doubted but that cacao will some day become one of the most important of the Philippine agri-horticultural exports.

Fruit-growing, in the pomological sense of the word, is scarcely even in its infancy. Fruits, fresh, canned and dried, were imported to the value of $241,686 in 1911, while the total horticultural exports for the same year were but $24,053. It is thus seen that the foreign markets are all neglected, and yet there is no doubt but that Hongkong could readily absorb many times the amount of fruit that is sent there and that much could be exported to Japan, China and Cochin-China, and even Australia. This latter country imported in 1910 citrous fruits alone to the value of $107,445 from California and the Mediterranean countries, and, in fact, the Philippines themselves, the home of some of the citrous fruits, yearly import oranges, pomelos and lemons that are far inferior to the home-grown product; canned pineapples are imported from Singapore and Hawaii. However, there has been an awakening during the past year to the anomaly of this situation, and considerable attention is beginning to be paid to the fruit industry.

Owing to the long distance to the principal large foreign markets, and the perishable nature of most of the fruits cultivated, the Philippine Islands can hope to export but few fresh fruits, such as mandarins, oranges, pomelos, bananas and mangoes, and while the production of fresh fruit for export should become a considerable item, the manufactured products—fruit canned, dried, crushed and grated, made into jams, jellies, marmalade, fruit syrups, flavoring extract and wine—are destined to be of primary importance. In this form the Philippine fruits can compete with others for the world's markets.

Two fruits only, the banana and the mandarin, can be said to be systematically planted and cultivated, and even then the care they receive is primitive. Practically all the mandarins are grown in a small district in Batangas; budding and grafting is never practised; marcottage is sometimes employed in the propagation of particularly choice fruit trees, principally the chico. Even the mango, the most famous of the Philippine fruits, is grown on the edges of the rice-paddies, on hillsides and along the roads, instead of in regularly planted orchards.

Also, there are many districts in the Philippines in which such hardy and vigorous species as the mango, tamarind, chico, and breadfruit have not yet been introduced and there are others such as the bauno (*Mangifera verticillata*), marang (*Artocarpus odoratissima*), and kambog (*Dillenia speciosa*), which are unknown except in their native habitat.

The banana (*Musa sapientum*, *M. paradisiaca*, and *M. humilis*) is the most important of the Philippine fruits as a food; the flower-buds are eaten as a vegetable. There are probably over one hundred varieties of bananas in the Philippines, of which the following are the most important in order of their enumeration: Lacatán, Latundán, Sabá, Gloria, Bungulan, Daliring señora, Butuan, Matabia, Lacatán morado, Ni-lanzon, Tundoc. These varieties occur under many synonyms.

Next to the banana, the papaya (*Carica Papaya*), is the most generally grown fruit in the Philippines; a very good variety of this fruit is being gradually disseminated. The second most important fruit commercially is the mandarin (*Citrus nobilis*), which has already been referred to. The trees are all seedlings, but the fruit is nevertheless remarkably good and uniform in appearance, size, and quality. The production of the other citrous fruits is very limited, and in the order of their importance they are: Pomelo (*Citrus grandis*), calamondin (*C. mitis*), lime (*C. aurantifolia*), orange (*C. sinensis*), cabuyao (*Papeda histrix*). The variation in these species is very great and several natural hybrids occur. (See Philippine Bureau of Agriculture, Bulletin No. 27.)

1993. Typical house near Manila. Roof made of nipa palm.

1994. A typical laborer's hut in Manila. Also made of nipa palm.

1995. A hay (rice grass) carrier in Manila.

The mango (*Mangifera indica*) is the third most important commercial fruit in the Philippines and, excepting the mandarin, the only one that is exported. The three most important types of mangoes are Carabao, Pico and Pahutan. Only the first two are worthy of cultivation. Cavite, Cebu, Bohol, Nueva Ecija, Pangasinan and Zambales lead in mango-production. (See Philippine Bureau of Agriculture, Bulletin No. 18.)

The pineapple (*Ananas sativus*) is grown chiefly for its fiber and is cultivated principally in Samar, Occidental Negros, Tayabas and Bulacan. Bataan supplies Manila with pineapples during its season; the variety grown is of good quality and flavor. Cayenne and Spanish were introduced in 1912. The chico (*Achras Sapota*) is grown to a considerable extent and is of good quality; the guava (*Psidium Guajava*) is naturalized everywhere; the lanzon (*Lansium domesticum*) is well esteemed, and Manila is fairly well supplied with this fruit during its season. The soursop (*Annona muricata*) and the sugar-apple (*Annona squamosa*) are the most generally grown fruits of the genus; the custard-apple (*Annona reticulata*) is less esteemed. The duhat (*Eugenia jambolana*) is the most generally distributed species in the genus; the yambo (*Eugenia Jambos*) is very rare. The mangosteen (*Garcinia Mangostana*) and durian (*Durio zibethinus*) have not yet been introduced north of Mindanao.

The betelnut (*Areca Catechu*) is of great local importance at present but the use of this stimulant is decreasing.

The above are the most important of the Philippine fruits. The following are grown to more or less extent:

Alubihod (*Spondias mangifera*), alupag (*Euphoria cinerea*), bauno (*Mangifera verticillata*), bignay (*Antidesma bunius*), bitoñgol (*Flacourtia sepiaria*), bobog, (*Sterculia fœtida*), camanchile (*Pithecolobium dulce*), camia (*Averrhoa Bilimbi*), carambola (*Averrhoa Carambola*), cashew (*Anacardium occidentale*), catmon (*Dillenia philippinensis*), cereza (*Muntingia calabura*), chico-mamey (*Lucuma mammosa*), ciruela (*Spondias purpurea*), citron (*Citrus medica*), date (*Phœnix dactylifera*), fig (*Ficus Carica*), granadilla (*Passiflora quadrangularis*), grape (*Vitis vinifera*), iba (*Phyllanthus acidus*), igot (*Eugenia* sp.), jak (*Artocarpus integrifolia*), kambog (*Dillenia speciosa*), kaki (*Diospyros Kaki*), kayam (*Inocarpus edulis*), lemoncito (*Triphasia aurantiola*), libas (*Garcinia Vidallii*), longan (*Euphoria Longana*), mabolo (*Diospyros discolor*), macopa (*Eugenia javanica* and *E. malaccensis*), manzanita (*Zizyphus jujuba*), marang (*Artocarpus odoratissima*), mulberry (*Morus nigra*), pangi (*Pangium edule*), pili nuts (*Canarium ovatum*, and *C. pacyphyllum*), pomegranate (*Punica granatum*), santol (*Sandoricum indicum*), strawberry (*Fragraria vesca*), tamarind (*Tamarindus indica*), togop, (*Artocarpus elastica*), zapote (*Diospyros Ebenaster*).

As the islands are becoming better explored, other fruits will undoubtedly be added to this list.

The following fruits have been introduced by the Bureau of Agriculture within the last few years:

The avocado (*Persea gratissima*), cherimoya (*Annona Cherimola*), roselle (*Hibiscus Sabdariffa*), hevi (*Spondias cythereæ*), hogplum (*S. lutea*), tiess (*Lucuma Rivicoa* var. *angustifolia*), boracho (*Lucuma salicifolia*), ceriman (*Monstera deliciosa*), tree tomato (*Cyphomandra betacea*), caranda (*Carissa Carandas*), carissa (*Carissa bispinosa*), *Cecropia palmata*, pitanga (*Eugenia uniflora*), caymito (*Chrysophyllum Cainito*), *Dillenia indica*, ginepap (*Genipa americana*), *Phyllanthus emblica*, bael (*Ægle Marmelos*), cattley guava (*Psidium Cattleianum*), biriba (*Rollinia orthopetala*), casimiroa (*Casimiroa edulis*).

During the past year, the leading varieties of citrous fruits have been introduced from their respective countries; also a large collection of mango varieties from India.

The most important vegetables are the sweet potato, here called camote (*Ipomœa Batatas*), ubi (*Dioscorea alata*), bolót (*D. fasciculata*), ñame (*D. sativa*), and gabe (*Colocasia antiquorum*), of all of which there are several varieties. If the cassava (*Manihot utilissima*) may be classed as a vegetable, this is another of great importance. The tomato, eggplant, sitao (*Vigna Catjang*), patani (*Phaseolus lunatus*), sincamas (*Pachyrhizus angulatus*), squash (*Cucurbita maxima*), and pumpkin (*Cucurbita Pepo*) come next in importance.

The following vegetables are also grown in the Philippines: Apalia (*Momordica balsamina*), batao (*Dolichos Lablab*), beet (*Beta vulgaris*), buting (*Phaseolus vulgaris*), cabbage (*Brassica oleracea*), cadyos (*Cajanus indicus*), carrot (*Daucus Carota*), chile (*Capsi-

cum minimum and *C. annuum*), coletis (*Amarantus oleraceus*), condol (*Benincasa cerifera*), cucumber (*Cucumis sativus*), endive (*Cichorium Endivia*), garlic (*Allium sativum*), lettuce (*Lactuca sativa*), libato (*Basella rubra*), magtambocao (*Canavalia ensiformis*), malungai (*Moringa oleifera*), melon (*Cucumis Melo*), mungo (*Phaseolus Mungo*), mustard (*Brassica juncea*), okra (*Hibiscus esculentus*), onion (*Allium Cepa*), pacupis (*Trichosanthes anguina*), panarien (*Tacca pinnatifida*), parsley (*Carum Petroselinum*), patola (*Luffa acutangula* and *L. ægyptiaca*), pea (*Pisum sativum*), pechay (*Brassica Pe-tsai*), potato (*Solanum tuberosum*), radish (*Raphanus sativus*), seguidilla (*Psophocarpus tetragonolobus*), turnip (*Brassica Rapa*), upo (*Lagenaria vulgaris*), watermelon (*Citrullus vulgaris*).

The sago palm (*Metroxylon Rumphii*) is indigenous in Mindanao and used by the inhabitants of that island in the preparation of sago.

The climatic conditions and soil for the cultivation of many of the spices are excellent. Certain species of vanilla grow wild in Mindanao and Luzon, and cinnamon (*Cinnamomum zeylanicum*) is indigenous to Mindanao. Black pepper (*Piper nigrum*), and ginger (*Zingiber officinale*) have been introduced, but nothing has ever been done to encourage systematic cultivation of spices. If the spice industry was properly fostered by the government until it was fairly well established, good varieties introduced and care taken to exclude dangerous fungi and insect enemies, it is believed that this industry would have a promising future in the Philippines.

It appears evident, from the researches made by E. D. Merrill, that there already was a botanical garden in existence in Manila in 1787, located where the Singalong Experiment Station of the Bureau of Agriculture now is. This was one of the first institutions of its kind established in the Philippines if not in the entire Orient. It was abandoned by the Spaniards, at what date is unknown.

The present botanical garden, so called, established in 1858, south of the Pasig River and west of Intramuros, containing an area of about 5 hectares, is a park rather than a botanical garden. The construction of Malate Park, intended to cover over 40 hectares is now in progress.

During the last two years, the Bureau of Education has paid special attention to school-gardening, which, if wisely persisted in, will undoubtedly greatly assist in elevating the standard of horticulture in the Philippines. Both the Bureau of Agriculture and the Bureau of Education are making large annual distributions of vegetable seeds, and the Bureau of Agriculture maintains two agri-horticultural demonstration farms, one located at Trinidad, Benguet, and the other in Iloilo. Coincident with the reorganization of the Bureau of Agriculture in force from the beginning of the fiscal year 1912, provision was made still further to extend the activity of the extension and demonstration work, and a division of horticulture was created. Much work has already been accomplished by this division in collecting data relative to Philippine horticulture, and work is in progress to assemble all food plants for study at the experiment stations. (Relative to the activities of the Bureau of Agriculture, consult the "Philippine Agricultural Review," a monthly publication issued by the Bureau.)

The Philippine Agricultural College, Los Baños, provides a course in horticulture and maintains a garden and nursery for practical demonstration work.

P. J. WESTER.

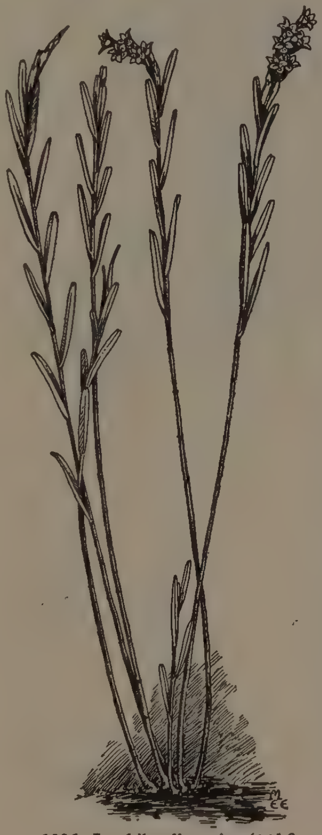
ISMÈNE: *Hymenocallis.*

ISNÁRDIA: *Ludvigia.*

ISOCHÌLUS (Greek, *equal lip*). *Orchidàceæ.* A group of tufted orchids, little cultivated. Plants epiphytic, with tall, slender, leafy sts., without pseudobulbs, bearing a few small fls. at the summit: sepals erect, free, keeled; petals similar but plane; labellum like the petals and united with them to the base of the column, somewhat sigmoid below the middle; column erect, long, without wings; pollinia 4.—About 5 species, Trop. Amer.

lineàris, R. Br. Fig. 1996. Slender, ¾–1⅓ ft. high, leafy: lvs. distichous, linear, striate, obtuse, emarginate, 1½ in. long: fls. purple, borne in a short, terminal spike. March. Growing on rocks and trees in thick woods, Jamaica, Trinidad, Brazil, etc. B.R. 745. L.B.C. 14: 1341. **I. màjor,** Cham. & Schlecht., of Mex., is taller, fls. larger and darker colored. HEINRICH HASSELBRING.

ISÓLEPIS: *Scirpus.*



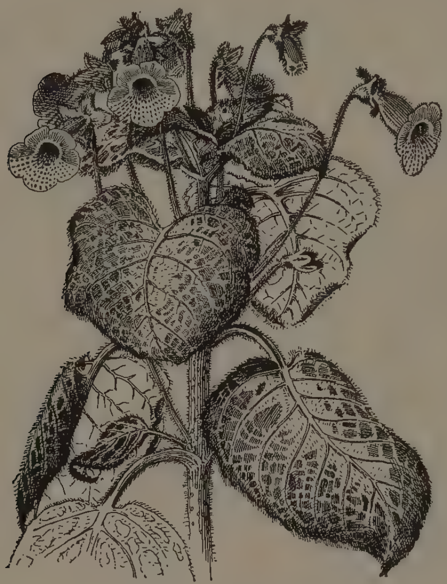
1996. Isochilus linearis. (×¼)

ISOLÒMA (*equal border*). Includes *Tydæa, Gieslèria, Sciadocàlyx, Brachylòma. Gesneriàceæ.* Greenhouse plants, very closely allied to Gesneria and Achimenes.

From Gesneria it is distinguished by absence of well-formed tubers and characters of caps. and anthers, and the 5 lobes of the disk equal; from Achimenes in the more tubular fls. and lobed disk. From Vanhouttea and Diastema the genus is separated technically by the open æstivation. Herbs, with creeping rhizome or base or roots: lvs. opposite, usually villose as in Gesneria: fls. scarlet, orange or vari-colored, usually peduncled in the axils; corolla cylindrical, enlarged above, erect or declined, the limb subequally 5-parted.—Species perhaps 50 in. Trop. Amer.

The culture is the same as for achimenes and gesneria. Seeds of the newer hybrids come quickly, and plants bloom the same year. It is probable that the pure species are not in the trade. Like achimenes, gesneria and gloxinia, they have been much hybridized and varied. It is probable that they are hybridized with achimenes and gesneria. It is not known how the current forms have originated. Some of the recent ones have fringed flowers (Gn. 55:348). Because of the variation and hybridization in cultivation, the names in this group are much confused, although few of them appear to be in the trade. The confusion is increased, also, by change in the generic name, from Isoloma to Kohleria. The genus Kohleria was founded by Regel in Flora, April, 1848. Later in the same year, Decaisne founded Isoloma in Revue Horticole, taking up, however, the name from Bentham who had used it for a section of Gesneria in his "Plantæ Hartwegianæ" in April, 1846. In 1848, also, Decaisne founded the genus Tydæa on *Achimenes picta* of Bentham (1844); but this genus is now by common consent included in

Isoloma (or Kohleria). When this plant, which is apparently the best known garden form, is taken over into Isoloma, it would naturally become *I. pictum;* but the plant first regularly given the name *pictum* under Isoloma is *I. pictum* of Planchon, 1850–51 (and Regel, 1854), which is founded on the *Gesneria picta* of Hooker (1849), and this is a very different plant from the cultivated *Achimenes* (or *Tydæa*) *picta*, and the latter must take a new name; and it assumes the name given it by Nicholson in 1888, *I. bogotense.*



1997. Isoloma bogotense. (×⅓)

bogoténse, Nichols. (*Achímenes pícta*, Benth., B.M. 4126, 1844. *Tydæa pícta*, Decne., R.H. 1848:468. *Kohlèria bogoténsis*, Fritsch, in Engler & Prantl, Nat. Pflanzenf. IV. 3*b*, 178, 1893. *Isolòma Tydæa*, Bailey, Cyclo. Amer. Hort. 836, 1900. *Isolòma píctum*, Hort., not Planch.). Fig. 1997. One to 2 ft., hairy: lvs. cordate-ovate, coarsely serrate, spotted and reticulated with pale green or silvery green, with a broad light zone down the center: fls. single, on long axillary sts., nodding, the orifice oblique and lobes obtuse, the upper longitudinal half of the fl. red, the lower half yellow and red-spotted. Colombia. B.M. 4126 (adapted in Fig. 1997). B.R. 31:42. F.S. 1:17, 18. *I. pictum*, Planch., F.S. 6:586 (*Gesneria picta*, Hook. B.M. 4431), is a different plant, apparently not in commerce.

amábile, Mott. (*Tydæa amábilis*, Planch. & Lind.). Erect, hairy: lvs. ovate, more or less tapering to the petiole, bluntly serrate, purplish on the veins: fls. hairy, pendent, dark rose dotted with purple, paler inside. Colombia. B.M. 4999. R.H. 1859, p. 25. F.S. 10:1070.

hirsùtum, Hort. Fig. 1998. Erect, hirsute on st. and lvs., free-flowering: lvs. ovate, acute, prominently petioled, close-toothed: fls. several on an axillary peduncle, hirsute, orange-scarlet, the rounded lobes darker-marked. Origin not clear. To be compared with the next.

eriánthum, Decne. (*Gesnèria eriántha*, Benth. *Brachylòma eriánthum*, Hanst. *Kohlèria eriántha*, Hanst.). Erect, 2–4 ft., the sts. and lvs. more or less fleshy and soft-hairy: lvs. long-petioled, ovate-lanceolate, dentate: fls. several on a peduncle, 1½–2 in. long, orange-red or cinnabar-red, the lobes rounded and the 3 lower spotted. Colombia. B.M. 7907.

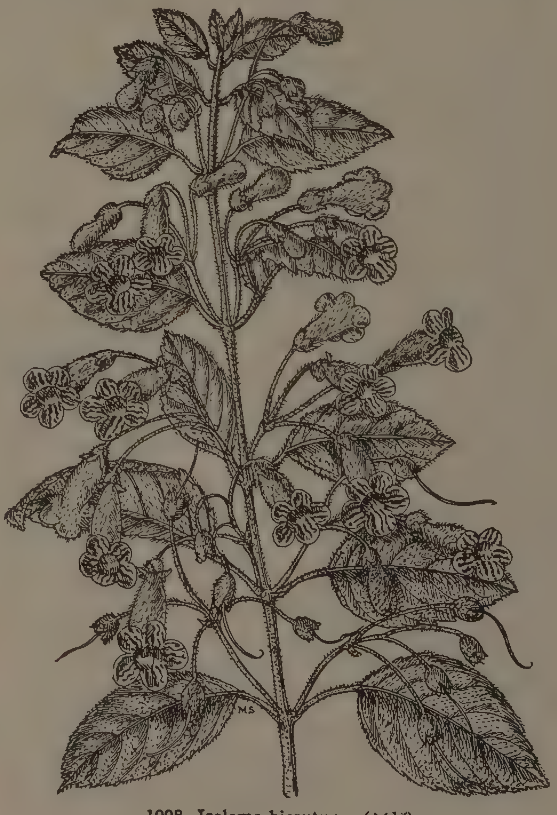
Cecíliæ, Nichols. (*Tydæa Cecíliæ*, André). Much like *I. amabile*, but lvs. marked with violet and silvery zones or blotches: fls. 2 or 3 from each axil, the fls. pale rose outside and striped in the throat, and the limb purple-spotted. Colombia. I.H. 23:260.

ocellàtum, Benth. & Hook. (*Achímenes ocellàta*, Hook). Short-hairy on the st.: lvs. ovate-acuminate, serrate, green: fls. small, on peduncles shorter than the lvs., the tube and short, rounded lobes red, the segms. marked with whitish and black spots. Panama. B.M. 4359.

jaliscànum, Wats. Fig. 1999. Herbaceous or somewhat woody at the base, 1 ft., pubescent: lvs. opposite, oblong-lanceolate to ovate-lanceolate to ovate, short-acuminate, short-stalked, serrate: fls. 2–4 on an axillary peduncle, the corolla an inch long, tubular and short-lobed, pubescent, scarlet. Mex.—A worthy plant, probably not in the trade. L. H. B.

ISONÁNDRA (Greek, *equal anthers*). *Sapotàceæ. Isonandra Gutta* (=*Palaquium Gutta*, Burck.). is a large-leaved East Indian tree belonging to this genus, which furnishes the best commercial gutta-percha. The name has appeared in one southern catalogue, but the plants were found to be not true to name. This plant should be called *Palaquium Gutta.* In Palaquium the floral parts are in sixes, stamens twelve and the seeds have no albumen, while in Isonandra the floral parts are in fours, the stamens eight, and the seeds albuminous.

Gútta, Hook. (properly *Palaquìum Gútta*, Burck.) One of the GUTTA-PERCHA TREES. Lvs. leathery, elliptic, abruptly pointed, 4 in. or more long, rusty-tomentose beneath, the primary nerves 24–30 on each side: fls. in axillary clusters on very short pedicels, the corolla ⅓in. long and with 6 elliptic obtuse



1998. Isoloma hirsutum. (×¼)

lobes; stamens 12; ovary 6-celled, becoming a small ovoid berry with 1 or 2 seeds: tree 40 ft. This is scarcely a horticultural subject. Malaya. R.H. 1898, p. 441.

ISOPỲRUM (from the Greek for *like*, and *wheat*, as the seeds resemble those of wheat). *Ranunculàceæ*. Dwarf stemless herbs sometimes used in the wild garden. Annual, or rootstock perennial: lvs. decompound, ternate; lfts. 3-lobed or cut, membranous: fls. white, regular, few or solitary, on slender scapes; sepals 5–6, deciduous; petals 5, very small or wanting: carpels 2–20, sessile; ovules 3 or more.—Fifteen to 20 species in temperate regions of the northern hemisphere. **I. thalictroìdes,** Linn., is cult. in alpine gardens, and has graceful foliage resembling a maidenhair fern. Six to 12 in. high: rootstock creeping: cauline lvs. alternate, 3-lobed or 3-foliolate: fls. white, resembling an anemone, in few-fld. terminal panicles; sepals oval, obtuse. W. Himalayas. April, May.—Thrives in any good garden soil. Prop. by seeds or by division of the roots in autumn. Very ornamental and good in masses. **I. grandiflòrum,** Fisch. Lvs. long-petioled; lfts. small, 2–3-lobed: scapes 3–4 in., equaling the lvs.; fl. solitary, 1–1¼ in. diam. Himalayas. G.C. III. 50:396. L. H. B.

1999. Isoloma jaliscanum. (×½).

ISÓTOMA (Greek, *equally cut* or *divided;* referring to the corolla, and true only by contrast with Lobelia). *Campanulàceæ*. Lobelia-like herbs, but with an entire corolla-tube (or only partially slit), and stamens attached near the top of the corolla: lobes of corolla 5 and nearly equal, spreading; upper anthers with terminal tufts: fls. solitary or in racemes, blue, purple or white (at least in the cult. species): lvs. alternate, entire, dentate or pinnatifid or even twice-pinnatifid: plants of various habit, some species erect, others creeping or acaulescent; annual or perennial.—Species 8, of which 6 are Australian, 1 W. Indian, and 1 in the Society Isls.

axillàris, Lindl. Perennial, flowering the first year so as to appear annual, but forming at length a hard rootstock, erect, with few spreading branches, 6–12 in.: lvs. linear, irregularly pinnatifid, 2–3 in. long, lobes linear: pedicels axillary, 2–6 in. long; fls. large, bluish purple, pale outside. Austral. B.M. 2702 (as *Lobelia senecioides*) and 5073 (as *Isotoma senecioides* var. *subpinnatifida*, which has the lobes again more or less pinnatifid). B.R. 964.—Probably not now in cult.

petræ̀a, F. Muell. Like the above, except that the lvs. are ovate-oblong or elliptical, with linear or lanceolate teeth or lobes which are not longer than the breadth of the body of the blade. Austral.—The plant in the trade is said to have cream-colored fls., and is sold as a "lemon verbena," a name which properly belongs to *Lippia citriodora.* L. H. B.

ISÒTRIA (Greek, *in equal threes*). *Orchidàceæ.* Terrestrial plants, with elongated fleshy roots, and scapose stem with a whorl of leaf-like terminal bracts. Flowers solitary or in 2's, erect or ascending; sepals narrow, about equal, longer than petals; lip somewhat 3-lobed, spurless, erect, crested; pollina 2, powdery-granular, tailless.—Species 2, E. U. S. See *Pogonia.*

verticillàta, Raf. (*Pogònia verticillàta*, Nutt.). Scapes 8–16 in. tall; bracts elliptic to oval, abruptly acuminate; sepals linear, 1–2 in. long, longer than the linear petals; lip erect, 3-lobed. E. U. S. B.B. 1:468.

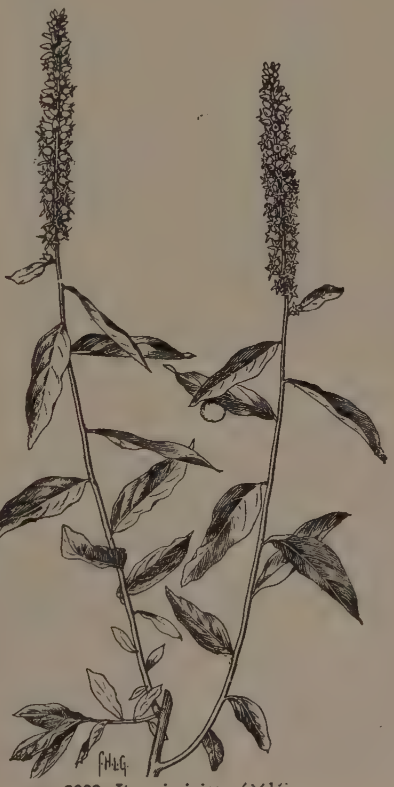
George V. Nash.

ISOTỲPUS: *Onoseris.*

ÌTEA (Greek name of the willow, applied here because it has willow-like leaves, or perhaps because it grows near the water). *Saxifragàceæ;* by some placed in a separate family, *Iteàceæ*. Trees and shrubs, numbering about 6 species, inhabiting tropical and subtropical Asia, and one of them in North America, *I. virginica*, a low, upright, somewhat coarse shrub, best known by its long, erect racemes of small white flowers appearing about July 1, in Massachusetts, and its brilliant autumn coloring.

The genus is characterized by alternate, narrow lvs., fls. in simple racemes which are terminal or axillary, white: calyx 5-toothed, with persistent lobes; petals 5, very narrow; stamens 5; ovary oblong, 2-celled: fr. a very narrow or a conical caps., which is 2-grooved, 2-parted when mature: some of the species are evergreen.

virgínica, Linn. Virginian Willow. Fig. 2000. A shrub, 1½–6 ft. high, usually not more than 2–3 ft. high, of upright, somewhat slender habit: lvs. deciduous, alternate, oblong, pointed, minutely serrate, smooth green above, pale and slightly pubescent below, petioled, without stipules, 1–3 in. long: fls. fragrant,



2000. Itea virginica. (×¼)

white, in solitary, erect, hairy, simple, dense, terminal racemes 2–6 in. long, given a greenish white effect by the stamens and pistils, not particularly showy, appearing late June and July. Pa. and N. J. to Fla. and La. B.M. 2409.—In nature it inhabits low, wet places. In cult. it seems to adapt itself to almost any soil. It is not perfectly hardy N., but grows rapidly and seems enduring of both sun and shade. In ornamental use it is planted in masses or mixed with other shrubs of similar character in the shrubby border or at the edge of woods. Its somewhat coarse character does not favor its approach to more refined objects. In autumn it becomes a brilliant red. It is prop. from seed, by cuttings and by division of roots, which spread slowly and form clumps of sts. It may be collected from the wild.

ilicifòlia, Oliver. Evergreen shrub, with holly-like spiny-toothed broadly elliptic lvs.: fls. small, greenish white, almost sessile, in a terminal drooping raceme 1 ft. or less long. Cent. China. G.C. III. 34:375; 42:123; 50:96. G.M. 54:567.—Hardy in parts of England.

A. Phelps Wyman.
L. H. B.†

ÌVA (named after *Ajuga Iva*, from its similar smell). *Compósitæ*. A genus of about twelve species of American shrubs or shrubby herbs with flowers suggesting those of Artemisia, or the common ragweed, but from which it differs in having heads all of one kind, the bracts of the involucre not united. This includes **I. frutéscens,** Linn, the MARSH ELDER or HIGH-WATER SHRUB, a native hardy perennial of no garden value, which is, nevertheless, on record as having been cultivated. It grows 3 to 12 feet high in salt marshes and on muddy seashores, has serrate leaves and flowers as inconspicuous as those of a ragweed. See B. B. 3:292 and the manuals.

IVÈSIA: *Potentilla.*

IVY. The common or English ivy is Hedera. **Boston I.**=*Parthenocissus tricuspidata.* **German I.**=Climbing Senecio and *Herniaria glabra.* **Ground I.**=*Nepeta Glechoma.* **Kenilworth I.**=*Linaria Cymbalaria.* **Poison I.**=*Rhus Toxicodendron.*

ÍXIA (Greek, *bird-lime;* said to refer to the juice). *Iridàceæ.* Attractive bulbs (cormose) from the Cape of Good Hope, with grass-like foliage and spikes of flowers in early spring, exhibiting a wide range of colors; usually flowered under glass, but can be grown in the open in the North with good protection.

Corm mostly globose, tunicated, fibrous-coated or nearly naked: st. simple or the infl. branched, about 1–2 ft. tall, bearing an erect spike or raceme of mostly 6–12 fls.: lvs. at the base of the st., erect, with perhaps a few smaller cauline ones: fls. funnelform or salverform with a slender sometimes elongated tube, and 6 nearly or quite equal segms., the colors white, yellow, orange, lilac, pink, crimson, red, purple or even green; stamens 3, attached in the throat, the filaments free or connate at the base; ovary obovoid or oblong, 3-celled and many-seeded, the style filiform with slender lobes: fr. a membranaceous obtuse 3-valved caps.—Species about 25 in S. Afr., 1 in Trop. Afr.

Ixias number their cultivated forms by the hundreds. Next to crocuses and freesias they have no rivals in point of popularity among spring-blooming bulbs of the iris family. Culturally they belong to the same class with babiana and sparaxis, which are also desirable and distinct in general appearance and coloring, but are surpassed by ixias in popularity and in number of varieties. Botanically, these three genera belong to the ixia tribe, in which the flowers are spicate, not fugitive and never more than one to a spathe. The stamens of Ixia are equilateral; those of Babiana and Sparaxis unilateral. Ixias have about six erect grass-like leaves arranged in two ranks; Babiana has plaited, hairy leaves. Bulb catalogues give no hint as to the parentage of the numerous named varieties. They may not mention *I. maculata* nor *I. columellaris,* which are probably the important parent stocks. Of the species recognized by Baker in Flora Capensis, apparently only *I. viridiflora* appears as a trade name, but *I. speciosa* and *I. paniculata* may be advertised under their synonyms *I. craterioides* and *I. longiflora.* Ixia flowers are charming in every stage of development. At first the flowers are erect and cup-shaped. They close at might and remain closed on dark days. As they grow older they open wider and become more star-shaped. Fig. 2001 shows the flowers in their drooping stage. The plants remain in flower for three weeks, although the faded flowers at the bottom of the spike should be taken off toward the end of the period. As cut-flowers, they are presentable for a week or two.

2001. Ixia flowers in their drooping stage. (×½)

For greenhouse bloom, ixia bulbs can be planted any time from September 15 to October 30, the sooner the better. In general, tender bulbs of small size tend to lose vitality when kept a long time in the dry air of warehouses. They should be planted an inch deep, five or six in a 5-inch pot, or eight to ten in a 6-inch pot. They like a compound of sandy soil and leaf-mold. It is probable that most of the failures with ixias are due to hasty forcing. The pots should be stored under a bench or in a rather dark cellar, at a temperature of 45°. The object is to hold back the tops while the roots are growing, in order to get stocky, well-colored, slowly started shoots. They need no water until growth has started. Then water carefully until the flowers come, as the young plants are liable to rot at the surface of the ground. While flowering, water freely. After flowering, some gardeners give the plants no water. Others keep the soil moist until the leaves turn yellow, and then gradually withhold water. As to temperature, the plants may be brought into a cool greenhouse (50°) when well started, and toward the end of January may be given 5° more heat if flowers are desired as early as the middle of March. Ixias have to be staked and tied. The old bulbs, from which the offsets have been removed, may be used again. Ixia bulbs, which are really fibrous-coated corms about ½inch thick, keep as well as freesias. Seedlings flower the third year.

In coldframes ixias give good results. Choose for the frame an open place, sheltered from north and west winds. In its construction give especial care to providing good drainage, to close-fitting and snug banking, so that frost, mice and moles can be kept out. A sandy soil, without manures, is safest and best for ixias. If fertilizers are used, they must be placed several inches below the bulbs, never in contact with them. As in outdoor culture, the bulbs must be planted late and in soil well dried by placing the sashes over the frame some time beforehand. Plant about 3 inches deep, as far apart, and treat afterward much as in greenhouse culture. Take off the sashes in early May to show the mass of rich, odd flowers which, ordinarily, will open about that time and last for several weeks. If the frame is to have other tenants through the summer, the ixias may be taken up after their tops are dead and stored in dry sand till planting time comes around again. Otherwise, merely cease watering as the tops of the ixias die down, and put on the sashes again, tilting them so that they will give air and shed rain. (L. Greenlee.)

Outdoor culture of ixia is likely to be more satisfactory than indoor culture, if one meets the few simple requirements. The planting of the bulbs should be delayed until the last moment, because ixias are more inclined than most things to make an autumnal growth. They should be planted 3 inches deep as late as November 30. In planting bulbs it is always well to sprinkle a handful of sand on the spot where they are to lie. This helps the drainage, especially on heavy lands, and prevents rotting. The bulbs should then be covered with about 3 inches of leaves, hay, or better still, pine-needles. In the latitude of Boston, ixia beds can be uncovered during the first week of April. However, there will still be sharp frosts to nip the tender shoots that have started beneath the winter covering. Consequently a little hay or other covering material should be left nearby, where it can be easily secured when a chilly evening threatens. In ten days the young sprouts will become sufficiently hardened to withstand any subsequent cold. Even such hardy things as alliums, when first uncovered, can hardly withstand any frost at all. It is, however, a mistake to wait two weeks longer and then permanently uncover the bulb beds, for by that time the early-starting things are likely to be so lank and long that they never attain ideal sturdiness. It is better to uncover too early than too late. The secret of success with ixias outdoors is largely in hardening the plants in early spring and in never allowing them to grow too fast under cover, where they become yellow and sickly. In winter, shutters may be placed over the bulb beds to shed the rain; but the bulbs do as well without this protection, though they may be later in starting. Of course, ixia bulbs cannot stand any freezing, and they must, therefore, be planted in unfrozen soil.—After flowering, let the bulbs remain in the earth until the end of July; then take them up, and store them, not in dry earth, but in boxes without any packing. Let them remain in a dry place until they are wanted for November planting. In the southern part of England, ixias can be planted 6 inches deep in hardy borders as late as December, and Krelage, perhaps thinking of still warmer regions, considers ixias as summer-blooming bulbs, and advises planting from October to December.—In the writer's experience, the flowers from the old bulbs are not at all inferior in succeeding years: indeed, the contrary has been the case, and the bulbs raised at home have been superior to the ones purchased. Amateurs are commonly advised to throw away the offsets because fresh bulbs are cheap. Yet the writer finds that many of the offsets bloom the first year and nearly all of them the second. Ixias have been raised commercially near Boston with every prospect of success. Ixias are amongst the most pleasing of all bulbs. With thousands in bloom in the month of June, they make a braver show even than tulips, and they are less known to the public. (W. E. Endicott.)

In California, ixias, with which may be grouped for cultural purposes such other South African irids as sparaxis, babianas, and tritonias, are of all bulbs the best adapted to California conditions, thriving outdoors with the minimum of care, increasing very rapidly by offsets, and even forming colonies from self-sown seed. Planting should be done as soon as the imported bulbs are available, usually in October. They should be put about 2 inches deep and as far apart as taste dictates,—say 3 inches, if space is valuable. Good drainage is essential and a sandy loam much better than heavy adobe, although the writer has grown them successfully in both. Divide every alternate year to prevent crowding. Pick the brightest place in the garden, as the flowers require strong sunlight to open them up well. This is especially true of the green kind, *I. viridiflora*.—To raise new varieties, sow seed in autumn, the resultant bulbs blooming the second season. Some of the best varieties in California are self-sown seedlings, the result of crosses between good named varieties in neighboring beds. After a start has been made, there is no reason why the American supply of these bulbs should not be grown in California, as they ripen very well and are of greater vigor than the imported ones.—Where space is limited, ixias may be planted among daffodils, thus renewing the show a month after the latter are over. As both bulbs ripen together, in harvesting this is no drawback. For garden effect, large plantings of separate, clear-colored, named varieties are much better than mixtures. The flowering season covers about six weeks, the pretty cerise *I. speciosa*, (*I. crateroides*) blooming in March, while the brilliant brick-red Vulcan is sometimes as late as May. (Sidney B. Mitchell.)

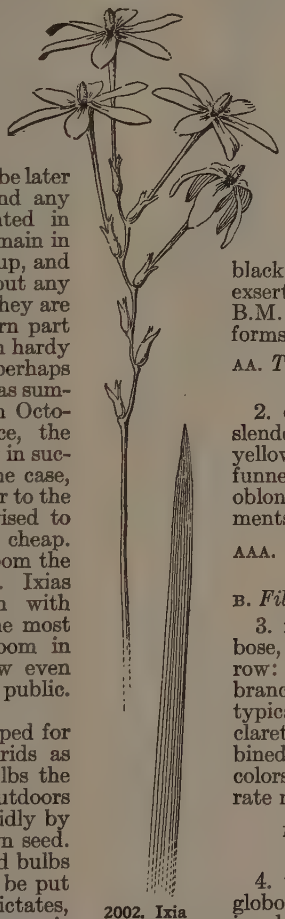
A. *Tube of perianth long, and somewhat dilated below the limb.*

1. **paniculàta,** Delaroche (*I. longiflòra*, Berger). Fig. 2002. Corm ¾in. or less diam., with brown tunics: basal lvs. 2–3, linear and glabrous, to 1½ ft. long: st. 1–3 ft., sometimes branched: fls. many, in lax erect spikes, the tube to 3 in. long and straight, the limb cream-white, the segms. obtuse, often tinged red and sometimes with a blackish base; anthers wholly or partially exserted, about as long as the filaments. B.M. 256; 1502.—There are two botanical forms or varieties.



2002. Ixia paniculata. (×⅓)

AA. *Tube of perianth short, and dilated below limb into a distinct funnelform.*

2. **odoràta,** Ker. Lvs. very narrow: st. slender, distantly branched: fls. bright yellow, fragrant, in a short spike; tube funnel-shaped, ½in. long, the segms. oblong; anthers equaling the free filaments. B.M. 1173.

AAA. *Tube of perianth short and cylindrical (not dilated upward).*

B. *Filaments more or less connate or joined.*

3. **monadélpha,** Delaroche. Corm globose, with fibrous coverings: lvs. very narrow: st. slender, simple or somewhat branched: fls. few, in a short spike; segms. typically lilac, but there are forms with claret-red, blue or pale yellow segms. combined with eyes and markings of various colors, some of which have received separate names. B.M. 607; 1378.

BB. *Filaments all free at the base.*

C. *Fls. green.*

4. **viridiflòra,** Lam. Corm depressed-globose, ½in. diam., with fibrous covering: lvs. narrow, strongly ribbed: fls. many, in a long loose erect spike, typically with

pale green segms. and black throat. B.M. 549. L.B.C. 16:1548. F.S. 2:124. Var. **càna,** Eckl. Segms. pale blue; throat black. B.M. 789 (as *I. maculata amethystina*). Var. **cæsia,** Ker. Segms. pale lilac; eye greenish. B.R. 530.

CC. *Fls. in other colors.*

D. *Throat of fl. (eye) differently marked from the segms.*

5. **maculàta,** Linn. Fig. 2003. Corm globular, 1 in. or less diam., covered with parallel fibers: lvs. about 4, linear, ribbed, 6–12 in. long: sts. slender, 1–2 ft., simple or branched: fls. many, in dense and erect spikes, typically yellow; tube slender; limb bell-shaped, with a dark purple or black mark at throat, the segms. oblong, obtuse. B.M. 539 (orange, as *I. conìca*). The natural varieties show the range of color: Var. **ochroleùca,** Ker. Segms. sulfur-yellow; eye brown. B.M. 1285. Var. **nìgro-álbida,** Klatt. Segms. white; eye black. Var. **ornàta,** Baker. Fls. flushed bright red or purple outside.

6. **columellàris,** Ker. Like *I. maculata,* but fls. typically with bright mauve-purple segms. and blue throat. B.M. 630.

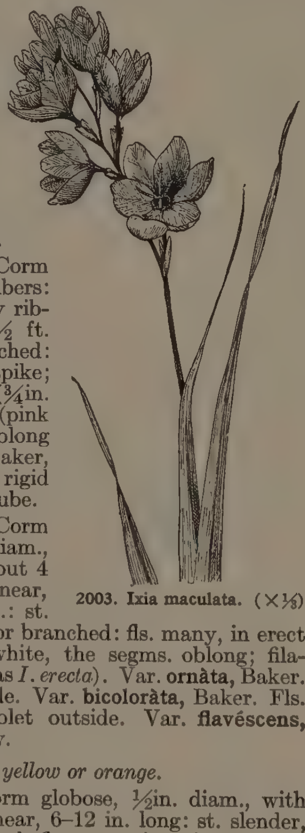
7. **ovàta,** Klatt. Like *I. maculata,* but has bright red fls. with purple-black throat. Var. **stellàta,** Klatt, has the throat yellow.

DD. *Throat not differently marked.*

E. *Color white or whitish (varying to tinted shades and colors).*

8. **aristàta,** Ker. Corm globose, with strong fibers: lvs. 3–4, linear, strongly ribbed: st. slender, to 1½ ft. high, simple or branched: fls. many, in a loose spike; perianth-tube slender (¾in. or less); limb whitish (pink in B.M. 589), with oblong segms. Var. **élegans,** Baker, has narrower and less rigid lvs., and much shorter tube.

9. **polystàchya,** Linn. Corm globose, ¾in. or less diam., with fine fibers: lvs. about 4 at base and 2 on st., linear, strongly ribbed, 6–12 in.: st. slender, 1–2 ft., simple or branched: fls. many, in erect spikes; perianth-limb white, the segms. oblong; filaments short. B.M. 623 (as *I. erecta*). Var. **ornàta,** Baker. Segms. tinged red outside. Var. **bicoloràta,** Baker. Fls. pale yellow, tinged violet outside. Var. **flavéscens,** Baker. Fls. pale yellow.



2003. Ixia maculata. (×⅓)

EE. *Color yellow or orange.*

10. **lùtea,** Baker. Corm globose, ½in. diam., with fibrous covering: lvs. linear, 6–12 in. long: st. slender, 1–2 ft., simple or branched: fls. many, in a dense spike, deep bright yellow. B.M. 846.

EEE. *Color shades of red or lilac.*

11. **flexuòsa,** Linn. Very like *I. polystachya,* except that fls. are in shades of red or lilac or lilac-tinged outside. B.M. 624.

12. **pàtens,** Ait. Corm globose, to ¾in. diam., with fine fibers: lvs. about 4, linear, 6–12 in.: st. erect, 12–18 in., sometimes branched: fls. several, in a somewhat dense erect spike, pale red.

13. **speciòsa,** Andr. (*I. crateroìdes,* Ker.). Corm globose, small, with matted fibers: lvs. from base about 6, linear: st. slender, usually simple: fls. few, in a short and erect spike, the oblong segms. dark crimson; limb campanulate. B.M. 594. Gn.W. 21:648.

WILHELM MILLER.
L. H. B.†

IXIOLÍRION (Greek, an *ixia-like lily*). *Amaryllidàceæ.* Three or four species of hardy bulbs from western and central Asia, with umbels of deep blue or violet six-lobed flowers, borne in spring.

Perianth regular, without tube above the ovary; segms., oblanceolate, acute; stamens shorter than the segms., attached to their claws; ovary club-shaped, 3-celled, becoming a 3-valved caps.: lvs. very narrow, mostly at base of the st. The nearest cult. allies are Alstrœmeria and Bomarea, which have no distinct rootstock, while Ixiolirion has a bulbous rootstock. The bulbs should be lifted in autumn and stored.

montànum, Herb. (*I. Pállasii,* Fisch. & Mey.). Bulb ovoid, 1 in. thick, with a neck 2–3 in. below the basal tuft of lvs.: st. about 1 ft. long: lvs. about 4, persistent, and a few smaller ones above: fls. on long unequal pedicels, about 4, and often 1 or 2 fls. below; perianth bright lilac according to Baker, 1½ in. or less long. Syria to Siberia. B.R. 30:66. F.S. 22:2270. R.H. 1880:310. J.H. III. 31:583.

Var. **tatàricum,** Herb. (*I. tatáricum,* Hort. *I. Lédebourii,* Fisch. & Mey.). Sts. more slender: lvs. awl-shaped: fls. all in a terminal umbel, smaller than the type. Altai Mts. G.C. II. 19:757. Gn. 75, p. 188. Gn. W. 21:685. J.H. III. 42:532.

I. Kolpakowskiànum, Regel (Kolpakowskia ixiolirioides, Regel), is perhaps a form of above, but has a smaller bulb, fls. 2–4 in a terminal umbel, and the perianth-segms. ¾–1 in. long: lvs. about 4 in a basal tuft and 1 or 2 small ones above. Turkestan. Gt. 1878:953.

L. H. B.

IXÒRA (a Malabar deity). *Rubiàceæ.* Warmhouse woody plants with showy flowers in clusters and evergreen foliage; handsome and desirable.

Shrubs or small trees with opposite or verticillate lvs. and terminal or axillary usually dense corymbs of very showy white, rose or scarlet fls. on bracteate pedicels: corolla very long and slender-tubed, the throat sometimes barbed, the limb 4- or 5-lobed and wide-spreading; stamens 4 or 5, inserted on the throat, the filaments short or none; ovary on a fleshy disk, 2-loculed, the style filiform and exserted, 2-branched; ovules solitary: fr. a hard or fleshy 2-pyrenous berry.—Species upward of 150, in the tropical parts well around the globe.

There are many garden forms of Ixora under Latin names, and these complicate a botanical account of the genus. Some of the named garden ixoras are the following: *Amabilis,* pinkish, suffused orange. *Aurantiaca,* orange-red; compact. *Chelsonii,* fls. brilliant salmon-orange. *Colei.* fls. pure white: cross of *I. coccinea* and *I. stricta* var. *alba.* *Conspicua,* fls. yellow, becoming orange. *Decora,* yellow. *Dixiana,* fls. deep orange; G. 27:363. F. S. R. 3, p. 275. *Fraseri,* fls. scarlet in the tube, and brilliant salmon above; G 7:529. *Illustris,* orange. *Incarnata,* flesh-color. *Insignis,* rose. *Ornata,* salmon-orange. *Pilgrimii,* orange-scarlet. *Princeps,* fls. whitish, becoming orange; said to have come from Java. *Profusa,* rose. *Regina,* fls. shaded violet-salmon, in large dense clusters. J.H. III. 42:159. *Sanguinea,* fls. crimson, shaded with violet. *Speciosa,* yellow. *Splendens,* orange. G.Z. 23:193. *Splendida,* crimson-orange. G.Z. 26, p. 217. I.H. 29:463. *Venusta,* orange. *Westii,* fls. pale rose, becoming brilliant; hybrid. Gn. 42:496. G.M. 36:35. G. 25:457. *Williamsii,* fls. reddish salmon.

The ixoras are perhaps the best tropical warmhouse plants that combine the showiest of flowers with fine evergreen foliage. They are of easy culture, and should be far oftener seen in tropical plant-houses.—They may be propagated at any season, but early spring is probably best. Take good strong cuttings, with four pairs of leaves on them, and pot them singly, in 2-inch pots, in two parts clean sharp sand, and one of peat. Plunge the small pots in a cutting-bed, where the bottom-heat is about 70°. Be sure they are shaded from the strong sun. In a few weeks the small pots will be filled with roots, and the plants may be shifted into a pot two sizes larger, and removed from the propagating-bed, and placed in a light position in a house where the night-temperature is about 65°.—The compost in which they are potted may be equal parts of fibrous loam, peat, and sand, adding about a sixth part of broken charcoal. When they grip the soil in this pot, cut them back, leaving two joints above the earth. If desired, the plants may be flowered in the smallest size of pot, and for decorative work they are then very useful; but if large plants are wanted quickly, keep them growing right along, never allowing the ball of the plant to get into a mat of roots until the desired size of pot is reached. After they have reached a 6-inch pot, they give the best satisfaction, if they are potted entirely in the fiber of a good loam, all the fine material being shaken out of it. Pot them rather firmly and keep up a night temperature of 65°. In winter it may be 5° less. —From March until the end of September, a very light shade over them is necessary, to keep the foliage in a perfect condition. After flowering is the best time to trim these plants into shape. Cut them back to one joint, unless some of the shoots are required longer, to preserve the symmetry of the plant. Before pruning ixoras, it is a good plan, after flowering, to keep them on the dry side for about a month. Never, however, allow the plants to suffer for lack of water. Just let them get to the wilting point, then water. This treatment firms up the wood equally, and when they are cut back, the young growths start all at the same time. By following this method the plant will flower more equally all over. Large plants of some of the varieties will give three crops of flowers a year; the variety *Fraseri* is an example. Plants in large pots will do well for several years without repotting, if fed liberally with manure-water. Green cow-manure, fertilizers such as Clay's soft-coal soot, an ordinary handful to a two-and-a-half-gallon watering-pot, or, for a further change, horse-urine, a 3-inch potful to the same amount of water, agrees well with ixoras, when they are well rooted. Water twice between applications with clean water. Insects that affect ixoras may be kept in check by a judicious use of the syringe, and fumigations with hydrocyanic gas as advised for other plants. (George F. Stewart.)

INDEX OF BOTANICAL SPECIES.

(For horticultural names, consult a preceding paragraph.)

acuminata, 2.
amboinica, 13.
Bandhuca, 7.
barbata, 3.
blanda, 6.
chinensis, 6.
coccinea, 6, 7, 12.

macrothyrsa, 8.
odorata, 4.
parviflora, 1.
rosea, 6.
salicifolia, 9.
stricta, 6.

A. *Fls. white (sometimes tinged pink).*

1. **parviflòra,** Vahl. Evergreen tree, with subsessile oblong or elliptic-obtuse lvs. 3–6 in. long: cymes sessile, with 3–5 pairs of short branches, the fls. in subglobose clusters; corolla white, glabrous, the tube only ⅓in. long, and the lobes oblong. India.

2. **acuminàta,** Roxbg. Glabrous shrub: lvs. various, from elliptic to linear-oblong, or the floral sometimes rounded or obovate and sessile while the others are petioled: cymes corymb-like, contracted and densely fld. sometimes as if almost capitate, 2–4 in. across; corolla pure white and fragrant, ⅔in. across, the lobes narrow and obtuse. India.

3. **barbàta,** Roxbg. Large glabrous shrub: lvs. stalked, elliptic, somewhat acute, thin, the upper pair usually small and sessile and cordate: cymes much broader than high, short-stalked, sometimes 1 ft. across, the branches being long, slender and spreading; corolla white, woolly at the mouth, the tube 1–1½ in. long and lobes narrow. India. B.M. 2505; 4513. J.F. 1:26.

4. **odoràta,** Hook. Small shrub: lvs. large, broad-ovate or obovate-lanceolate, acute or acuminate, thick, to 1 ft. long, the lower ones attenuate to a petiole: cymes or panicles much divided, 1 ft. or more across, with purplish branches; corolla very long (4–5 in.), white changing to yellowish brown; stamens somewhat protruding; fls. very fragrant. Madagascar. B.M. 4191.

5. **laxiflòra,** Smith. Shrub, slender, 3–4 ft.: lvs. oblong-lanceolate, acuminate, short-petioled: cymes or panicles trichotomous and very open, large, terminal; corolla white tinged pink, the tube 1½ in. long, limb cut to the base and the lobes very distinct; calyx red; fls. very fragrant. Guinea. B.M. 4482. J.F. 1:21.

2004. Ixora congesta.
(×⅓)

AA. *Fls. usually in shades of red (sometimes varying to rose and to orange-scarlet).*

6. **chinénsis,** Lam. (*I. stricta*, Roxbg. *I. coccínea*, Hort., not Linn. *I. blánda*, Ker. *I. crocàta*, Lindl. *I. ròsea*, Sims). Apparently the common species, known in greenhouses as *I. coccinea:* glabrous shrub, with sessile or subsessile lvs. which are obovate or obovate-oblong, and slender-tubed fls. in dense corymbs, the corolla-lobes short and rounded and the tube ¾–1 in. long. Malayan archipelago and China. B.M. 169 (as *I. coccinea*); 2428. B.R. 100; 782.—Runs into nearly pure white forms. There are said to be yellowish fld. forms. Prince of Orange, a popular variety, is said to be a form of this species.

7. **coccínea,** Linn. (*I. grandiflòra*, Bot. Reg. *I. Bandhùca*, Roxbg.). Much like the last, but lvs. oblong with mostly rounded or cordate base and sometimes an

apiculate tip, and corolla-lobes broad and acute, and the tube 1–1¾ in. long. E. Indies. B.R. 154; 513.

8. **macrothýrsa,** Teijsm. & Binn. (*I. Dúffii,* Moore). Very large, glabrous: lvs. a foot long, linear-oblong to oblong-lanceolate: cluster very large, 8 in. across, bearing very many deep red tinged crimson fls., with lanceolate obtuse lobes about ½in. long. E. Indies. B.M. 6853. G.M. 50:582. F.E. 19:115.—One of the finest of the genus.

AAA. *Fls. in shades of yellow or orange.*

9. **fúlgens,** Roxbg. (*I. salicifòlia,* DC.). Shrub with erect slender polished branches: lvs. petioled, linear-oblong to obovate-oblong, more or less acute or acuminate, shining above and with 20–30 pairs of sunken nerves: cymes sessile or short-peduncled, corymb-like, large, with spreading slender branches, the fls. short-pedicelled; fls. orange-scarlet or orange becoming scarlet; calyx-teeth very short and obtuse; corolla-tube 1¾ in. or less long, the lobes ovate and acute. India. B.M. 4523. J.F. 1:38.

10. **congésta,** Roxbg. (*I. Gríffithii,* Hook.). Fig. 2004. Evergreen tree in its native haunts, glabrous except the cymes: lvs. very large (6–12 in. long), stalked, elliptic or elliptic-oblong, acute or acuminate: cymes sessile or nearly so; fls. orange-yellow, changing to reddish, the segms. rounded. India. B.M. 4325. J.F. 1:50.—Much like *I. fulgens,* differing in stouter habit, very large and usually coriaceous broader lvs., stout not spreading branches in the cyme, and the fls. sometimes sessile.

11. **javánica,** DC. Glabrous shrub with lvs. 4–7 in. long, ovate-oblong, acute or acuminate: corymb terminal, long-peduncled with forking coral-red branches; fls. deep orange-red, the lobes rounded, the corolla-tube 1½ in. long, slender, red. Java. B.M. 4586. J.F. 2:156.

12. **lùtea,** Hutchinson (*I. coccínea* var. *lùtea,* Hort.). Differs from *I. coccinea* by laxer infl. and pale yellow fls. with larger ovate-rhomboid corolla-lobes. Of garden origin. B.M. 8439.

13. **amboínica,** DC. Shrub: lvs. large, short-petioled, ovate-oblong, acuminate, undulate, glabrous: cyme (or corymb) trichotomously divaricately compound; corolla-lobes acute. Amboyna (Moluccas).—Apparently in the trade as *I. amboina,* with long-lasting "showy orange-yellow flowers." L. H. B.

J

JABOTICÁBA. This name is applied in southeastern Brazil to the fruits of several species of Myrciaria, notably *M. cauliflora*, and *M. jaboticaba*, of the family Myrtaceæ. See *Myrciaria*.

The jaboticabeira, or jaboticaba tree, occurs not only in the wild state in various parts of Minas Geraes, São Paulo, Rio de Janeiro and adjoining states, but is commonly planted in gardens, and the fruit, which does not differ much in character among the various species, is held in the highest esteem by Brazilians of all classes. When well grown the tree is extremely handsome, reaching a height of 35 or 40 feet, with an umbrageous, dome-shaped head of light green foliage, the new growth pink. The persistent entire leaves are opposite, ovate-elliptical to lanceolate, acute or acuminate at the apex, generally glabrous, varying from ¾ inch to over 3 inches in length. The flowers are small, white, with four petals and a prominent cluster of stamens. They are produced singly or in clusters directly upon the bark of the trunk and limbs. The season of flowering and fruiting varies with the different species and in different localities; sometimes two or more crops a year are produced.

The fruit is nearly sessile or with a slender peduncle about 1 inch long, and is round or slightly oblate in form. It is ½ inch to 1–1½ inches in diameter, glossy, maroon-purple in color, and crowned with a small disk at the apex. The skin is thicker than that of a grape, and considerably tougher. The translucent, juicy pulp, white or tinged with rose, is of a most agreeable vinous flavor, remarkably suggestive of the grape, to which the jaboticaba is frequently compared. The seeds, one to four in number, are oval to round in outline, compressed laterally, ¼ to ⅜ inch long. When heavily laden with fruit, the tree is a curious sight. Not only is the trunk covered with glistening jaboticabas, but the fruiting extends out to the ends of the small branches as well.

The fruit is usually consumed when fresh, but in former days was used by the Indians for the manufacture of wine. It is sometimes made into jelly or jam. In the markets of Rio de Janeiro, jaboticabas sell for about 25 cents a pound, and considerable quantities are shipped in from Minas Geraes and São Paulo.

The tree prefers a soil that is rich and deep. Its growth is slow, six to eight years being required for it to come into bearing. Propagation in Brazil is almost always by seed, but inarching or some other vegetative means is necessary to perpetuate good varieties. There is much variation among seedlings. In California the jaboticaba makes very slow growth, and is adapted only to the most protected locations. It has been planted in Florida very recently, and may prove adapted to some sections of that state. When young the trees are very susceptible to frost, but when they have attained a few years' growth they will withstand slight frosts without serious injury. For a more complete account, see "Journal of Heredity," Vol. V, No. 7, 1914.

F. W. Popenoe.

JACARÁNDA (Brazilian name). *Bignoniàceæ.* Handsome tubular-flowered trees and shrubs, grown far South and also under glass.

Leaves opposite, 2-pinnate, rarely 1-pinnate; lfts. usually numerous, entire or dentate: fls. showy blue or violet, mostly in terminal or axillary panicles, often very freely produced; calyx small, 5-toothed; corolla-tube straight or curved, regular at the base or somewhat constricted above the ovary and broadened above; corolla-limb somewhat 2-lipped, the 5 lobes rounded and spreading and nearly equal; disk thick and cushion-like; perfect stamens 4, didynamous; staminode about as long as the stamens, club-shaped at the apex and often bearded at the top: fr. an oblong, ovate or broad dehiscent caps.—Species about 50, in the American tropics. Prop. by cuttings of half-ripened wood. Under glass they are considered to be warmhouse subjects.

ovalifòlia, R. Br. (*J. mimosæfòlia,* D. Don). Tree, 50 ft. and more: lvs. distant, spreading, oblong, villous: fls. blue (and a white variety) more or less horizontal. Brazil. B.R. 631. B.M. 2327. R.H. 1897:132. G.C. III. 36:224. G.M. 49:71.—*J. ovalifolia* perhaps ranks among the best flowering trees or shrubs for subtropical regions. It is now much recommended as a street tree in S. Calif., it being deciduous only in early spring. The foliage is as finely cut as a fern, symmetrical and elegant. The lvs. are decussate, distant, each one with 16 or more pairs of pinnæ, each pinna having 14–24 pairs of lfts. The plant bears loose, pyramidal panicles, 8 in. high, of 40–90 blue fls., each 2 in. long and 1½ in. wide, which have a long, bent, swelling tube and the 2 lobes of 1 lip smaller than the 3 other lobes. It is one of the best of foliage plants for the S., valuable alike for florists' decorations, conservatory, subtropical bedding in the N., or for lawn specimens in Fla., where, if cut back by frost, it rapidly recovers its beauty. It stands pruning well, and can be kept in regular form. There is some confusion between the names, *J. ovalifolia* and *J. mimosæfolia,* both being made in the year 1822.

cuspidifòlia, Mart. As compared with *J. ovalifolia,* lvs. said to attain a larger size and to have more lfts., fls. larger and in larger panicles, and brighter blue, tree more vigorous. Lvs. glabrous, with 8–10 pairs of lfts. and the lfts. again divided into 10–15 pairs, the ultimate lfts. entire, lanceolate, cuspidate at apex, the secondary rachis winged: fls. in large terminal thyrse, blue-violet, the corolla nearly 1½ in. long. Brazil, Argentina; advertised in S. Calif.

chelònia, Griseb. Tree, 30–90 ft., of globular shape: foliage fern-like, very ornamental: fls. large, blue, in strict terminal panicles 1 ft. long; calyx-lobes lance-linear and narrowly acuminate; corolla glandular-puberulent. Paraguay, Argentina.—Wood said to be veined with rose, and valued in S. Amer. for cabinet work.

acutifòlia, Humb. & Bonpl. Tree, glabrous: lvs. 2-pinnate, the lfts. 6–8 pairs and ultimate lfts. many and acuminate, entire, the petiole canaliculate and rachis winged: corolla silky, the tube straight, violet: panicle terminal and axillary. Peru.—Offered abroad.

L. H. B.†

JACK BEAN: *Canavalia.*

JACK-FRUIT: *Artocarpus integrifolia.*

JACK-IN-A-BOX: *Hernandia.*

JACK-IN-THE-PULPIT: *Arisæma.*

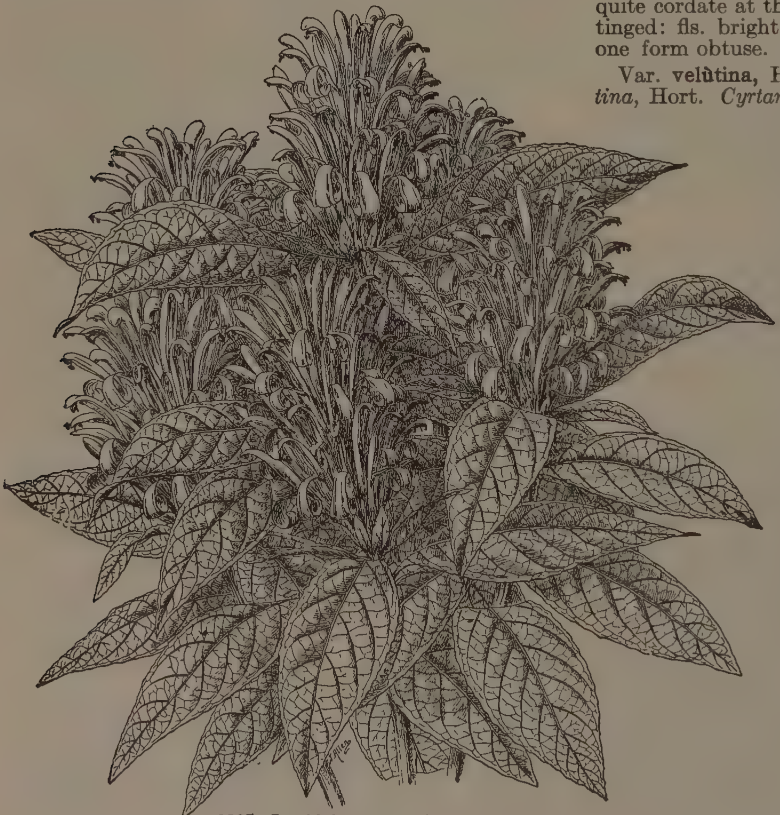
JACKSÒNIA (named for George Jackson, a Scotch botanist). Syn. *Piptómeris. Leguminòsæ.* Stiff, leafless shrubs or subshrubs, sometimes grown as greenhouse subjects: branchlets often phyllodineous or lf.-like, very much branched and spinescent: lvs. replaced by very minute scales at the nodes: fls. yellow, or yellow and purple, in terminal or lateral racemes or spikes, or scattered along the branches: bracts small, scale-like. —About 40 species, principally in W. Austral. Jacksonias are rarely seen in cult. They thrive in loam and peat soil. Prop. by cuttings from half-ripened shoots, rooted in sand, during April. *J. sericea,* Benth. A large shrub, decumbent, ascending or tall, with pendulous branches: fls. solitary or in irregular, terminal, loose racemes; calyx-lobes linear, about as long as the corolla. W. Austral. L. H. B.

JACOBÆA: *Senecio.*

JACOBÍNIA (probably a personal name). Including *Cyrtanthèra, Libònia, Sericógraphis, Sericobònia. Acanthàceæ.* Plants cultivated under glass for their narrow-tubular red, orange or yellow flowers.

Glabrous herbs, or sometimes shrubs: lvs. opposite and entire: fls. variously disposed, sometimes solitary, sometimes fascicled or spicate; calyx deeply 5-parted, with linear or awl-shaped segms.; corolla more or less 2-lipped, 1 lip 2-lobed and the other 3-lobed; stamens 2; staminodia represented by 2 hairy elevations on the corolla-tube; disk ring-like or cupulate; pistil ripening into an oblong or ovate caps., the style filiform.—Species 20–40, depending in part on the definition of the genus, from Mex. to Bolivia and Brazil.

Jacobinias, in common with other acanthads, are much confused as to species. A closely allied genus is Justicia, which, among other characters, is distinguished by having spurs or appendages at the base of the anther-lobes, whereas Jacobinia has no such appendages. Most of the garden plants called Justicias are Jacobinias. Other allied genera are Aphelandra, Dianthera, Adhatoda, Thyrsacanthus, Eranthemum, Barleria, Dædalacanthus.



2005. Jacobinia carnea. (×⅓)

In their native places, jacobinias are mostly subshrubs, but they are usually treated as herbs under cultivation. They are showy greenhouse or conservatory subjects. When well grown they are attractive plants, but they soon become weedy under neglect. They propagate very readily from cuttings, after the manner of fuchsias, and the most satisfactory plants are usually those that are allowed to bloom but once. Most of them thrive well under conditions suited to begonias.

A. *Fls. in a more or less dense terminal panicle or thryse; corolla long, more or less curved. (Subgenera Cyrtanthera, Pachystachys.)*

cárnea, Nichols. (*Justícia cárnea,* Hook. *Cyrtanthèra magnífica,* Nees. *Justícia magnífica,* Pohl. *Jacobínia magnífica,* Benth. & Hook.). Fig. 2005. Strong forking herb or subshrub, blooming when 1 or 2 ft. high, but becoming several feet high if allowed to grow: sts. 4-angled: lvs. opposite, lanceolate to ovate-lanceolate to oval-oblong, narrow or broad at base, attenuate to apex, wavy-margined, veiny, downy, sometimes a foot long: fls. rose-purple (varying to flesh-colored), ascending, arched at the top and the lower lip recurving, borne in dense terminal spike-like thyrses. Brazil. B.M. 3383. B.R. 1397. G.F. 5:317 (reduced in Fig. 2005). G. 24:238. G.W. 3, p. 439; 15, p. 704. F.E. 22:320.—A handsome old plant, of comparatively easy cult. in a conservatory temperature. Cuttings made in Feb. or March should bloom early the following winter. Young plants are usually most satisfactory, the old ones being kept over only for cutting stock. Give rich soil, and plenty of water in the growing season. This plant is said to have been distributed as *Whitfieldia lateritia.*

Pohliàna, Benth. & Hook. (*Cyrtanthèra Pohliàna,* Nees). Much like *J. magnifica,* but more robust and leafy: lvs. ovate-acuminate and rounded or nearly or quite cordate at the base, more glabrous, often purple-tinged: fls. bright crimson: bracts short-acute, or in one form obtuse. Brazil. G. 27:677. F.S.R. 3, p. 49.

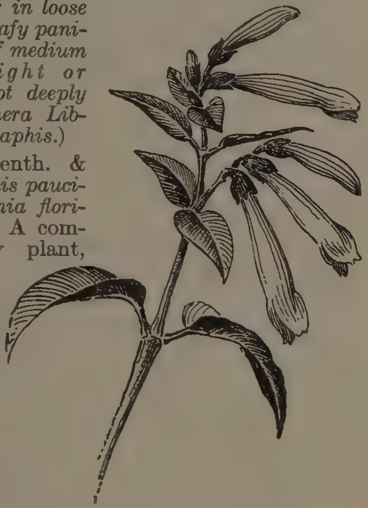
Var. **velùtina,** Hort. (*J. velùtina* and *Justícia velùtina,* Hort. *Cyrtanthèra Pohliàna* var. *velùtina,* Nees). Dwarf: bracts obtuse: lvs. villous-pubescent on both surfaces: fls. 2 in. long, rose-color. Brazil. Gng. 7:212; 16:24. A.F. 14:998.—A worthy plant of comparatively recent intro. in commerce. It is an excellent pot subject and has been considerably advertised as the "new dwarf *Justicia velutina.*" A profuse and continuous bloomer. Cultural remarks under *J. carnea* apply also to this.

coccínea, Hiern. (*Justícia coccínea,* Aubl.). Erect herb or subshrub, usually grown from cuttings each year and treated as a pot subject: 2–5 ft. high: branches terete: lvs. elliptic or ovate-lanceolate, entire, glabrous or nearly so: fls. crimson, in a dense terminal spike, pubescent, the long upper lip more or less arched and the lower one reflexed. Brazil. B.M. 432. G.W. 15, p. 704. Gn.W. 21:57.—Blooms in summer. Said to be known sometimes as *Aphelandra cristata.*

chrysostéphana, Benth. & Hook. (*Cyrtanthèra chrysostéphana,* Hook. f.) Herbaceous, glabrous or very nearly so, obtusely 4-angled: lvs. 5–6 in. long, petioled, ovate or ovate-lanceolate, acuminate, with red ribs: fls. in an erect terminal dense corymb, 2 in. long, golden yellow, on very short pedicels, the bracts linear-lanceolate and dark green; calyx ⅓in. long, with long subulate lobes; corolla glabrous, slightly curved, the upper lip oblong-lanceolate and vaulted, the lower lip oblong and reflexed and 3-lobed. Mex. B.M. 5887. Gn. 71, p. 563. J.H. III. 45:543. G. 27:678. G.M. 45:849. Gn.W. 21:51.—An attractive winter-flowering warmhouse subject.

AA. *Fls. scattered or in loose more or less leafy panicles; corolla of medium length, straight or nearly so, not deeply cleft.* (*Subgenera Libonia, Sericographis.*)

pauciflòra, Benth. & Hook. (*Sericógraphis pauciflòra,* Nees. *Libònia floribúnda,* C. Koch). A common conservatory plant, subshrubby, but usually treated as a pot-plant, with terete, short-jointed, close-pubescent branches: lvs. elliptic or elliptic-oblong, short and rather small, entire, very short-stalked: fls. 1 in. long, tubular, drooping, or nearly horizontal, scarlet with yellow at the end, the lips short. Brazil. —A most floriferous plant, almost as easy to grow as a fuchsia, and to be handled in essentially the same way.



2006. Jacobinia penrhosiensis. (×½)

Ghiesbreghtiàna, Benth. & Hook. (*Cyrtanthèra Ghiesbreghtiàna,* Decne. *Sericógraphis Ghiesbreghtiàna,* Nees. *Justícia Ghiesbreghtiàna,* Lem. *Aphelándra Ghiesbreghtiàna,* Hort.). Lvs. narrower (lance-ovate) and longer, acuminate: fls. in a terminal, very loose panicle, tubular, scarlet, appearing at the same season as those of *J. penrhosiensis.* Mex. F.S. 4:339. Gt. 98. —Intro. by Ghiesbreght; but when the plant was transferred to the genus Jacobinia the name was mispelled *Ghiesbrechtiana.* A good winter bloomer.

penrhosiénsis (*Libònia penrhosiénsis,* Carr.). Fig. 2006. Much like *J. pauciflora,* but lvs. more pointed and fls. larger and more showy. R.H. 1876:50. Gng. 2:131.—It is an excellent plant, and is taking the place of *J. pauciflora.* It is a hybrid of *J. pauciflora* and *J. Ghiesbreghtiana.* Another and very similar hybrid of the same parentage is *Sericobònia ígnea,* Lindl. & André. I.H. 22:198. *J. penrhosiensis* is a winter bloomer, a little earlier than *J. pauciflora.* Cuttings struck in spring make full blooming subjects by fall and early winter. This and *J. pauciflora* are common conservatory plants.

spicígera (*Justícia spicígera,* Schlecht. *Justícia atramentària,* Benth. *Justícia Mohíntli,* Moc. & Sesse. *Sericógraphis Mohíntli,* Nees. *Jacobínia Mohíntli,* Benth. & Hook. *Drejèra Willdenowiàna,* Nees). Undershrub, erect, pubescent: lvs. long-ovate to lanceolate, thick: fls. 1 in. long, axillary, secund, orange-yellow; corolla-tube elongated, inflated above, the upper lip somewhat arched, and entire, the lower lip spiral and 3-toothed. Mex.—Fls. said by some to be pale purple.

suberécta, André. Herb, velvety pubescent: sts. prostrate, with erect flowering branches: lvs. opposite, petioled, ovate, obtuse, to 2½ in. long: fls. in 1–10-fld. peduncled cymes, the bracts spatulate-obovate and obtuse; calyx-tube short and nearly hemispheric; corolla bright scarlet, the slightly curved tube about 1¼ in. long, pubescent outside; upper lip slightly emarginate and ovate, the lower 3-toothed and oblong. Uruguay. B.M. 8350. R.H. 1900:210.—Handsome warmhouse plant, suitable for baskets.

J. Líndenii, Nichols. (Justicia Lindenii, Houll.), is a Mexican subshrub, with long-ovate opposite decussate lvs., and a dense fascicled head of orange-yellow fls.: divisions of calyx linear; corolla long-tubular, 2 in. or more; 2 stamens attached in lower part of corolla. Does not appear to be in the trade. R.H. 1870:250.

L. H. B.

JACQUEMÓNTIA (after Victor Jacquemont, a French naturalist; died 1832). *Convolvulàceæ.* Subtropical and tropical mostly climbing herbs, grown for the convolvulus-like bloom.

Allied to Ipomœa and Convolvulus, to which they are probably inferior for garden cult. They are distinguished from Ipomœa by having 2 stigmas instead of 1; and from Convolvulus by having the stigmas ovate or oblong instead of linear-filiform to subulate. Lvs. entire, or rarely toothed or lobed: fls. not large, blue, white or violet, in either dense clusters or loose racemes, sometimes even solitary; corolla more or less campanulate, the plicate limb 5-angled or obscurely 5-lobed.—Species 60–70 in Trop. Amer. and as far north as S. C., also 1 in Trop. Afr. and 1 in Hawaii.

Jacquemontia pentantha makes an attractive greenhouse climber for summer and autumn flowering, but is not so desirable for this purpose as several species of Ipomœa. It is likely to become leggy. Propagated readily by seeds or cuttings. For cultural directions, see *Ipomœa.*

pentántha, G. Don (*J. violàcea,* Choisy. *Convólvulus pentánthus,* Jacq.). St. perennial, somewhat shrubby at base, twining 6–8 ft., pubescent or nearly glabrous: lvs. cordate to ovate-lanceolate, acuminate: peduncles slender, bearing 5–12 fls. in a loose cymose cluster; corolla about 1¼ in. wide, short-funnelform, sharply 5-angled, rich violet-blue. June-Sept. Trop. Amer., and as far north as Fla. B.M. 2151. B. 4:197. P.M. 6:219. In var. **canéscens,** Hort. (*J. canéscens,* Benth.), the whole plant is covered with short, brownish down. B.R. 33:27.

tamnifòlia, Griseb. Plant annual, usually low and erect, at length twining if support is near, covered with tawny yellow hairs: lvs. cordate-ovate, long-petioled: peduncles bearing many fls. in dense involucrate clusters; fls. less than ½in. long, violet. Cult. and waste ground, S. C. to Ark., and southward.

S. W. Fletcher.
L. H. B.†

JACQUÍNIA (Nicholas Joseph de Jacquin, 1727–1817, collector and painter of West Indian plants). *Myrsinàceæ;* by some separated, with Clavija and Theophrasta, in *Theophrastàceæ.* Tropical American trees and shrubs, seldom cultivated far South for ornament.

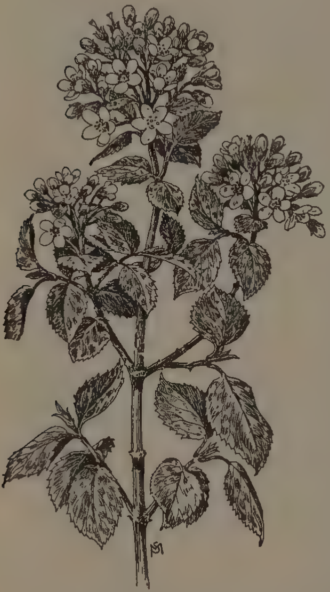
Leaves opposite or somewhat verticillate, rigid, margined, entire: fls. white, purple or orange, borne in racemes, umbels or singly; corolla 5-fid, wheel- to salver-shaped, crowned at the throat and between the lobes with 5 roundish appendages (staminodia); stamens 5, inserted far down in corolla-tube, the filaments subulate: berry leathery, few to several-seeded. In the allied genus Theophrasta the corolla is cylindrical, shortly 5-lobed, the appendages are fastened at the base of the corolla instead of the throat, and the berry is many-seeded.—By the latest monographer (Mez, Engler's Pflanzenreich, hft. 15, 1903), 33 species are described, of the warm parts of Amer.

keyénsis, Mez (*J. armillàris,* Chapm., not Jacq.). Lvs. cuneate-spatulate or obovate, blunt, revolute at the margin, usually whorled, 4 in. long, 1½ in. wide: berry ¼in. thick. S. Fla. and Bahamas. It is a low tree (about 15 ft.), with evergreen lvs. somewhat like box but obovate, and racemes of small white honey-scented fls., which appear in winter. It appears to be cult. only in S. Fla. and S. Calif. It is possible that the plant sometimes cult. is the *J. armillaris* of Jacquin, which Mez now calls *J. barbasco*, and which occurs in W. Indies. L. H. B.

JAMBÒSA: *Eugenia.*

JAMÈSIA (after its discoverer, Dr. Edwin James, 1797–1861, botanical explorer of the Rocky Mountains). Syn., *Edwínia. Saxifragàceæ.* Low hardy shrub of upright habit, with deciduous, opposite leaves, and white flowers in terminal, short panicles.

Leaves without stipules, petioled, serrate: calyx-lobes and petals 5; stamens 10; styles usually 3, rarely 4 or 5, slender; ovary superior, 1-celled: fr. a 3–5-valved, many-seeded, dehiscent caps.—One species in the Rocky Mts. from Utah to New Mex. Handsome shrub for borders of shrubberies or rocky slopes in sunny situations, thriving in any well-drained garden soil, best in a peaty and sandy one. Prop. by seeds or by cuttings of ripened wood.



2007. Jamesia americana. (×½)

americàna, Torr. & Gray (*Edwínia americàna,* Heller). Fig. 2007. Shrub, to 4 ft.: lvs. broadly ovate to oblong-ovate, acute, serrate, dentate, pubescent or almost glabrous above, whitish tomentose beneath, ½–2 in. long: fls. about ½in. across, white, sometimes pinkish outside. June. B.M. 6142. J.H. III. 32:37. Gn. 32, p. 522; 33, p. 606; 63, p. 105. Gt. 38, p. 103; 53, pp. 231, 232. L.I. 6. G.M. 52:85. Var. **ròsea,** Purpus. Fls. pink. ALFRED REHDER.

JÁNKÆA: *Ramondia.*

JANÙSIA (after Janus, the old Roman god with 2 faces). *Malpighiàceæ.* Twining or trailing plants, with 2 forms of yellow fls. in axillary clusters, the normal fls. having a gland-bearing calyx, a 3-angled style and 3 ovaries, and conspicuous clawed petals; abnormal fls. with an eglandular calyx, no style and 2 ovaries, and often rudimentary petals.—Ten to 15 species. **J. grácilis,** Gray, is offered in S. Calif. Sts. and branches very slender, twining or trailing: lvs. lanceolate-linear, both surfaces silky: peduncles mostly dichotomously 2-fld.; bracts linear, as long as the pedicels. Common throughout Texas, south of the Colorado, and west to New Mex. L. H. B.

JAPARÁNDIBA (probably a vernacular name). *Lecythidàceæ. Gustàvia,* which is retained by the "nomina conservanda" of the Vienna code. Upward of 20 trees and shrubs of Trop. Amer., little known in cult. Lvs. large, ovate or spatulate, alternate, serrate: fls. showy on 1-fld. somewhat umbelled peduncles; calyx-tube turbinate, the border entire or 4–6-lobed; petals 6–8, nearly equal; stamens many, in many series, annulate or cupulate; ovary 4–6-celled: fr. a fibrous few-seeded berry.—Some of the species may be found in choice collections of warmhouse plants, but only **J. speciòsa,** Kuntze (*Gustàvia speciòsa,* DC.), from Colombia, seems to be offered in this country (S. Calif.). Tree: lvs. thick, oblong-lanceolate, acuminate, narrowed at base, entire, punctulate above, reticulate beneath, about 3½ in. long: fls. fascicled, fragrant, 6-petaled, white, 2–3 in. long; calyx nearly entire and with the pedicel tomentose. Colombia.

J. gracíllima, Niedz. (Gustavia gracillima, Miers). Slender tree, glabrous: fls. 4 in. diam., rose-red, solitary or in pairs, from the lf.-axils on young plants and on the wood in old plants: lvs. close together, recurved, to 18 in. long, oblanceolate or much narrower, serrate. Colombia. B.M. 6151. G.Z. 21, p. 49.—*J. pterocárpa,* Niedz. (G. pterocarpa, Poit.). Fls. with 6 large obtuse white petals; calyx deeply 5–6-lobed; ovary 5-winged: lvs. thick, long-petioled, obovate-lanceolate, entire or very nearly so, acuminate: style elongated. Guiana. B.M. 5239.—*J. supérba,* Kuntze (G. superba, Berg. G. insignis, Lind.). Shrub or small tree: corolla 5–6 in. diam., cream-white, outside tinged rose: lvs. dark green and glossy, obovate-lanceolate, acuminate, much attentuate at base, sessile or nearly so, spinulose-toothed. B.M. 5069. L. H. B.

JASIÒNE (ancient name of no application to this plant). *Campanulàceæ.* Small blue-flowered or rarely white-flowered plants for the border or the rock-garden.

Jasione is easily distinguished from its allies by the fls. being borne in a head with an involucre, the calyx reduced to 5 very slender lobes, the corolla cut into 5 awl-shaped strips, and the anthers somewhat united at their bases; these characters make the infl. to resemble the Compositæ, but it is readily distinguished by the many-seeded caps.—Species 5 or 6, in Cent. and W. Eu. and the Medit. region. They differ widely in duration and habit. Prop. by division and seed. This includes the shepherd's scabious, a hardy herbaceous perennial plant of compact habit, about a foot high, and bearing globose heads 2 in. diam. composed of very many light blue fls. It is of easy cult. in any garden soil, grows either in full sunlight or partial shade, and is equally adapted for borders, edgings, or the rockery. The common annual scabious (Scabiosa) belongs to the teasel family, and has 4 stamens, while the shepherd's scabious has 5 stamens.

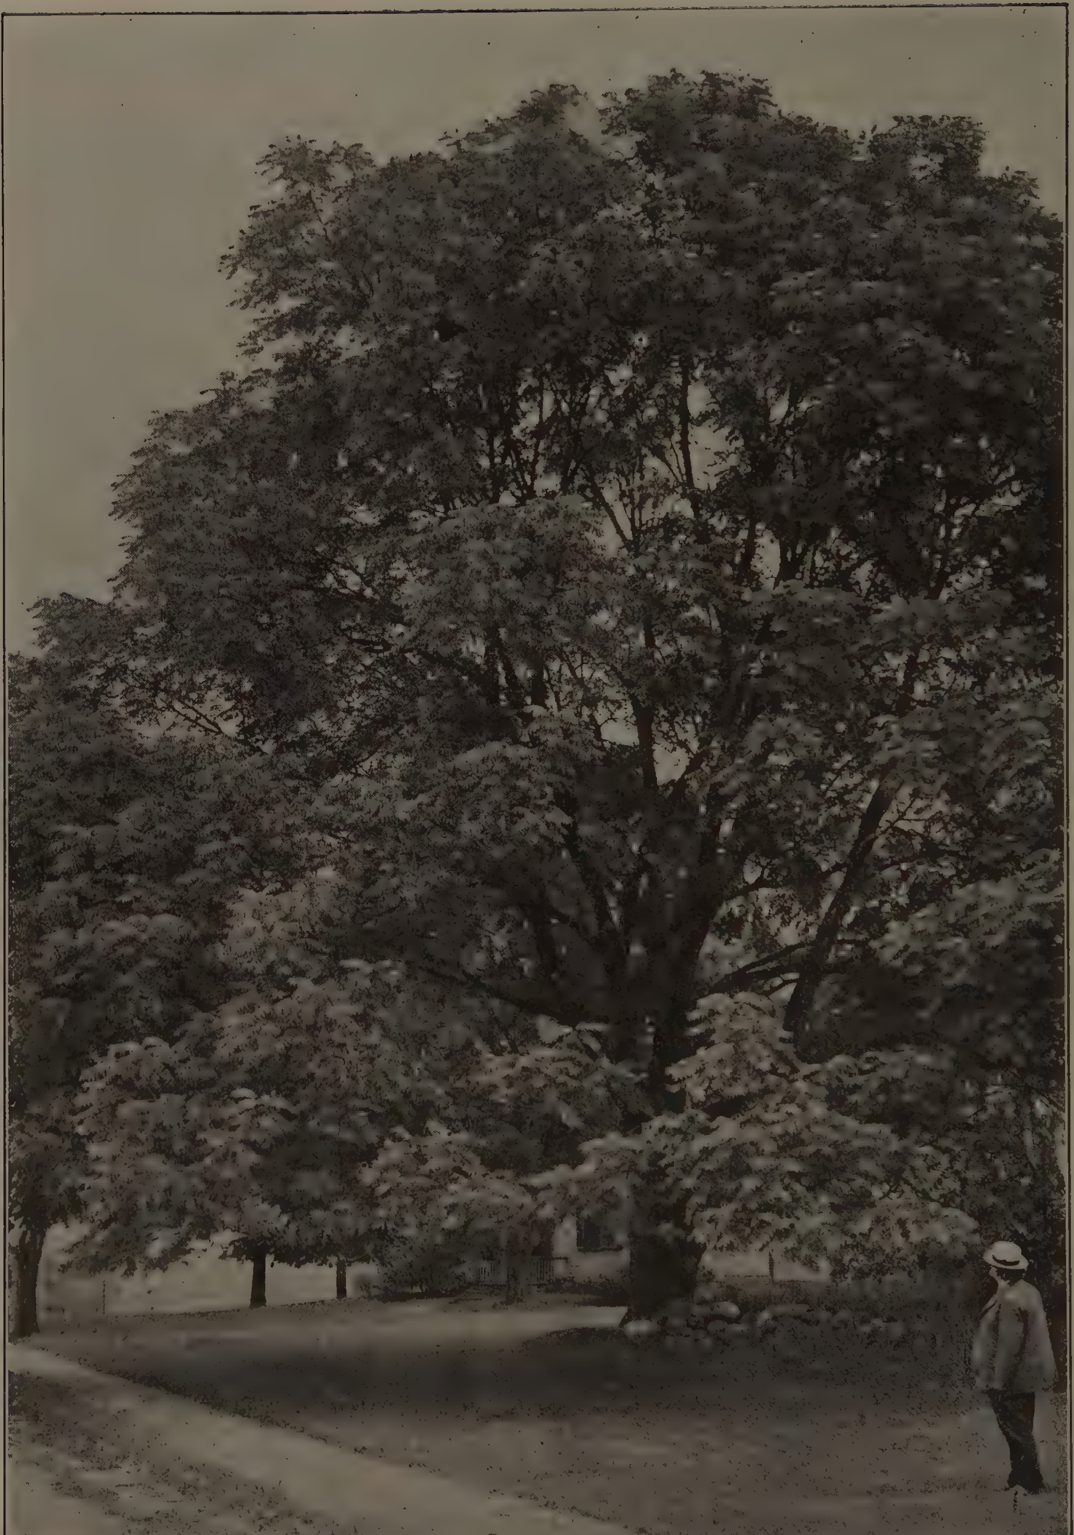
perénnis, Lam. SHEPHERD'S SCABIOUS. SHEEP SCABIOUS. SHEEP'S-BIT. Perennial: st. erect, sparingly if at all branched: root-lvs. obovate, in the non-floriferous plants forming a tufted rosette; st.-lvs. oblong-linear, entire; peduncles long, leafless; bracts ovate, serrate-dentate; fls. blue. S. Eu. July, Aug. B.R. 505. B.M. 2198.

montàna, Linn. Annual or biennial (if biennial, bearing a winter tuft or rosette of radical lvs.): sts. erect, 1 ft. high, sometimes short and more or less decumbent: lvs. linear or lanceolate, undulate, somewhat hairy: fls. pale blue, on long terminal peduncles; involucral bracts ovate. Great Britain to Caucasus.—The seaside form, (var. *littoràlis*) is said to be usually biennial. This species is also called sheep's-bit.

hùmilis, Lois. Dwarf, about 6–9 in. high, perennial: sts. simple, ascending: lvs. flat and entire, linear-obovate: fls. blue on short peduncles. Pyrenees; useful in rock-gardens. July, Aug. L. H. B.†

JÁSMINUM (Arabic name, from which have come Jessamine, Jasmin and Jasminum). *Oleàceæ.* JASMINE. JESSAMINE. Climbing or erect shrubs, with attractive flowers, mostly very fragrant, prized for planting in mild climates and frequently grown under glass.

Leaves opposite or alternate, pinnate but sometimes reduced to 1 lft. (petiole jointed): fls. on the ends of the branchlets, or twin, or in dichotomous cymes; corolla yellow or white, sometimes reddish, salver-shaped, the 4–9 or more lobes convolute in the bud, much exceeding the calyx; stamens 2, included in the corolla-tube; ovary 2-loculed, with 1–4 erect ovules: fr. a 2-lobed berry, or sometimes the carpels separate, the carpels mostly 2-seeded.—Probably upwards of 200 species, widely distributed in warm parts of Eu., Asia, Afr., and the Pacific region; nearly absent from Amer. The genus is closely allied to Ligustrum, but differs in the compound lvs. and twin-carpeled frs. Olea is also a related genus.



LX. Juglans nigra.—The black walnut.

Jasmines are of diverse horticultural groups. Some of them are hardy in the middle and southern states, whereas others are winter-flowering warmhouse plants. Most of them are known as coolhouse or temperate-house shrubs, of half-climbing habit. They are all of easy culture. They propagate readily by cuttings of nearly mature wood and by layers. The species are usually called jasmines although the word jessamine is really the same. *J. officinale* is the jessamine of poetry. Some of them (particularly *J. grandiflorum*) are grown for perfume-making. The Cape jessamine is Gardenia, although there is a *Jasminum capense.* Yellow or Carolina jessamine is Gelsemium. The hardiest kinds are *J. humile*, *J. fruticans*, *J. floridum*, *J. nudiflorum*, *J. primulinum*, *J. officinale*, but none of them is reliable north of Washington without protection, and even then only seldom north of Philadelphia.

A. *Lvs. apparently simple (reduced to 1 lft.).*

B. *Fls. white.*

C. *Calyx glabrous (No. 4 not considered).*

1. **simplicifòlium,** Forst. (*J. lùcidum*, Banks. *J. grácile*, Andr.). Climber, or sometimes a tree in its native place, glabrous or pubescent: lvs. opposite, mostly short-stalked, shining, varying from oblong-elliptic to ovate-lanceolate to cordate-ovate, acute or obtuse, usually less than 3 in. long: fls. white, in terminal forking, many-fld. clusters; calyx-teeth short and sometimes scarcely any; corolla-tube ⅓–½in. long, the acute lobes somewhat shorter. Austral. B.M. 980. B.R. 606.—Summer bloomer.

2. **trinérve,** Vahl. Tall-climbing, with terete glabrous branches: lvs. opposite, short-stalked, ample, ovate-oblong and acuminate, strongly 3-nerved from the base: fls. white, in small clusters; calyx-teeth narrow but much shorter than the long corolla-tube; corolla-lobes only half as long as the tube, acute. India. B.R. 918.—Perhaps only a form of *J. anastomosans*, Wall.

3. **rígidum,** Zenker (*J. ligustrifòlium*, Wall.). Compact dense rigid glabrous shrub, scarcely climbing: lvs. opposite, 2 in. long, ovate or elliptic, shining green, more or less acute at both ends but not acuminate, coriaceous, with reticulating nerves: fls. white, fragrant, in few-fld. dense sessile cymes; calyx-teeth linear, erect; corolla-tube 1 in. long, exceeding the lobes. India.

4. **multipartìtum,** Hochst. Erect bushy shrub, to 10 ft., the branches minutely puberulent: lvs. simple, ovate-lanceolate, less than 2 in. long, acute, somewhat undulate: fls. probably white, fragrant, solitary on the ends of branches; calyx 10-parted, the lobes setaceous; corolla-tube to 1½ in. long, the limb of several or many ovate-elliptic or linear-oblong acute lobes. S. Afr.

CC. *Calyx pubescent or pilose.*

D. *Teeth of calyx subulate.*

5. **Sámbac,** Soland. ARABIAN JASMINE. Climbing, the angular branchlets pubescent: lvs. opposite or in 3's (the ternate-lvd. specimens giving rise to the name *J. trifoliàtum*, Hort.), firm in texture, shining, nearly or quite glabrous, the petiole short and abruptly curved upward, elliptic-ovate or broad-ovate, either prominently acute or completely rounded on the end, entire, prominently veined: clusters 3–12-fld.; calyx-lobes linear and prominent, hirsute on the edges (sometimes almost glabrous); corolla-tube ½in. long; lobes oblong or orbicular. India. B.R. 1.—Much cult. in the tropics. Fls. white, but turning purple as they die. A full double button-fld. group is in cult., one form of which is the Grand Duke of Tuscany (or Grand Duke). The double form is shown in B.M. 1785. This double form sometimes passes as *J. trifoliatum*. *J. Sambac* is a perpetual bloomer, particularly in frostless countries, where it can stand in the open.

6. **undulàtum,** Ker. Climbing, with hairy branches, slender: lvs. opposite, short-petioled, rather small (about 2 in. long), ovate-lanceolate and acuminate, somewhat pubescent beneath, somewhat undulate: fls. 6–10, in terminal cymes, white, long-tubed; calyx-teeth short; corolla-tube ¾in. long, and slender; lobes half or less as long, acute. India. B.R. 436.—Lvs. sometimes ternate. Little known in cult. in this country.

7. **pubéscens,** Willd. (*J. hirsùtum*, Willd. *J. multiflòrum*, Andr.). Climbing, rusty-hairy: lvs. opposite, very short-petioled, rather thick, ovate-acute: calyx-teeth usually ⅔in. long (nearly or quite twice as long as in *J. undulatum*), with spreading yellow hairs: fls. white, much like those of *J. undulatum*, the lobes broad; often half-double. India. B.M. 1991. B.R. 15. J.H. III. 43:322.—Will stand some frost. Said to be a good dwarf glasshouse subject.

8. **gracíllimum,** Hook. f. Climbing or scrambling, soft-pubescent or hairy: lvs. opposite, very short-petioled, ovate-lanceolate, acuminate, the base cordate or truncate, bright green above and pubescent beneath, 1½ in. or less long: fls. white, in very large, dense hanging heads, an inch or more across, fragrant; calyx-teeth long and awl-like, half as long as the slender corolla-tube; corolla-lobes many (usually about 9), acute. N. Borneo. G.C. II. 15:9. B.M. 6559. J.H. III. 52:281. G.Z. 26, p. 97. G. 4:471; 7:233. F.S.R. 3, p. 15.—Long, lithe branches spring from near the ground and bear heavy clusters at their ends. Handsome floriferous winter bloomer. Nearly hardy in eastern part of N. C.

DD. *Teeth of calyx linear.*

9. **nítidum,** Skan. Slender-branched, somewhat pubescent, half-twining: lvs. opposite, shining, 2–3 in. long, elliptic-lanceolate, short-acuminate, the base somewhat cuneate, green above and pale beneath, lightly pilose along the rib, primary veins 3, the petiole less than ¼in. long and very pilose: fls. white, in small cymes, very fragrant, the pedicels about ⅓in. long; calyx pilose, the teeth linear and recurved and about ⅙in. long; corolla-tube narrow, ¾in. long; lobes of corolla 9–12, linear-lanceolate, spreading, 1½ in. broad. Admiralty Isls. (Bismarck Archipelago). R.B. 32, p. 182. R.H. 1907, pp. 110, 111. J.H. III. 60:237. Gn. 63, p. 61. A.F. 15:1237.—An excellent warmhouse climber.

10. **Màingayi,** Clarke. Scandent shrub with pilose branches: lvs. opposite, long-petioled, elliptic-lanceolate, 5 in. long, glabrous, acute at apex and rhomboid at base, coriaceous, the nerves 6–8 pairs and conspicuous and oblique and not inarched: fls. white, star-shaped, fragrant, in dense pubescent panicled cymes, on very short pedicels; calyx-tube ⅛in. long, campanulate, the teeth ⅓in. or less long, linear; corolla-tube ¾–1 in. long. the elliptic lobes acute, the limb 1½ in. diam. Penang (India). B.M. 7823.—Named for Dr. A. C. Maingay, the discoverer.

BB. *Fls. pink or red.*

11. **Beesiànum,** Forrest & Diels. Shrub, 1–3 ft.: lvs. simple and small, short-petioled, ovate or lanceolate,

1 in. or less long: fls. pink or deep rose, very fragrant; calyx-lobes linear, less than ¼in. long; corolla-tube short (less than ½in. long); lobes of corolla erect or spreading, broad-elliptic or suborbicular, short. W. China, altitude 8,000–9,000 ft. (Bees, Ltd., Liverpool.)

AA. *Lvs. of 3 or more lfts. (sometimes only 1 in No. 19).*

B. *The lvs. opposite.*

C. *Fls. white.*

12. **azòricum,** Linn. Climbing, glabrous or nearly so, the branches terete: lvs. evergreen, opposite, the lfts. 3, ovate-acuminate, the 2 side ones often smaller: calyx-teeth very small; oblong corolla-lobes about as long as the tube. Canary Isls. B.M. 1889.—A good white-fld. temperate-house species blooming in summer and winter.

13. **officinàle,** Linn. (*J. poéticum*, Hort.). Jessamine. Fig. 2008. Long, slender grower requiring support, but scarcely self-climbing, glabrous or very nearly so: lvs. opposite, odd-pinnate, the lateral lfts. 2–3 pairs and rhomboid-oblong-acute, the terminal one longer: fls. white, 2–10 in terminal more or less leafy clusters; calyx-teeth linear, ¼–⅔in. long, or sometimes as long as the rather short corolla-tube; corolla-lobes 4 or 5, oblong, more or less involute on the margins. Kashmir, 3,000–9,000 ft., Persia, and now widely distributed. B.M. 31. R.H. 1878, p. 428.—Long cult. The glossy foliage and fragrant white summer-blooming fls. render the plant very attractive in the S., where it is hardy. With protection it will stand as far N. as Philadelphia. Var. **affìne,** Nichols. (*J. affìne*, Hort.), is a form with larger fls. R.H. 1878, p. 428. There are double-fld. forms; also with yellow- and silver-edged lvs.

2008. Jasminum officinale. (×½)

14. **floribúndum,** R. Br. Much like *J. officinale*, but differs in calyx-teeth, and corolla-lobes wider and more obtuse and only half length of the tube: branches glabrous: lvs. opposite; lfts. 5, ovate, apiculate, the terminal one largest: fls. fragrant, white, in dichotomous axillary and terminal clusters; calyx-lobes subulate, longer than the bell-shaped calyx-tube; corolla-tube exceeding the calyx, to ¾in. long; segms. 5, ½in. long, oblong. Nile Land.

15. **angulàre,** Vahl. Climber with long 4-angled branches: lvs. opposite, hirsute; lfts. 3, orbicular, ovate to lanceolate, mucronate: fls. white, about 1½in. across, odorless, in 3's on axillary trifid peduncles; calyx glabrous, 5-toothed, the teeth equaling or shorter than the tube; corolla-tube many times longer than calyx, 1–1½ in., very slender; lobes of corolla 5–7, oval-lanceolate, somewhat obtuse or subacute. S. Afr. B.M. 6865. G.C. III. 28:360, 361. Var. **glabràtum,** Mey. (*J. capénse*, Thunb.). St. scarcely puberulent, the lvs. glabrous.

16. **grandiflòrum,** Linn. Catalonian, Italian, Royal or Spanish Jasmine. Nearly erect-growing, the branches drooping and angular, glabrous or very nearly so: lvs. opposite, the rachis flattened or winged, the lfts. 5–7, elliptic or round-elliptic or oval, mostly ending in a very small point or cusp, the terminal lft. mostly ovate-lanceolate and acuminate: calyx-teeth ¼in. long or rarely half as long as the corolla-tube; corolla star-shaped, larger than in *J. officinale*. India; naturalized in Fla. B.R. 91. G. 2:451.—Probably the best white-fld. species. Summer and fall, or nearly perpetual in warm countries. Much grown in Eu. for perfumery, and also a good greenhouse subject; young stock may be planted out in spring; will stand sun. Stands 10–12° of frost.

CC. *Fls. yellow.*

17. **nudiflòrum,** Lindl. (*J. Sieboldiànum*, Blume). Twiggy nearly erect shrub with 4-angled glabrous stiff branchlets: lvs. opposite, small, with 3 little ovate ciliate lfts., the entire foliage falling in autumn or when the growth is completed: fls. solitary, in early spring (or winter), from long, scaly buds, subtended by several or many small lf.-like bracts, yellow; calyx-lobes leafy and spreading or reflexed, shorter than the corolla-tube; corolla-segms. obovate, often wavy. China. B.R. 32:48. B.M. 4649. R.H. 1852:201. G.C. III. 11:181. G.W. 15, p. 300. H.F. 2:64. J.F. 3:320. Var. **aùreum,** Hort., has yellow-variegated foliage.—A most interesting species, reminding one of forsythia when in bloom. Hardy south of Washington, and blooming nearly all winter. With protection, it will stand as far north as Hudson River valley, and bloom very early in spring. In northern glasshouses, used mostly as a late winter and early spring bloomer. Strong-growing specimens need support.

18. **primúlinum,** Hemsl. Very like *J. nudiflorum*, botanically, but with larger lvs. which are sometimes well developed at flowering-time, and with much larger fls., the limb of the corolla exceeding the tube; a rambling very free-flowering evergreen glabrous shrub, with slender green 4-angled branches: lvs. petioled, of 3 lfts. which are almost sessile and 1 or 2 in. long, entire, oblong-lanceolate, shining above and paler beneath: fls. primrose-yellow with a darker eye, 1½–2 in. across, solitary on axillary bracted peduncles or branchlets; calyx-lobes lanceolate, slightly hairy; corolla-lobes usually 6, obovate-spatulate; stamens exserted. Yunnan, China, apparently as an escape from cult.; sometimes partially double. B.M. 7981. G.C. III. 33:197. R.H. 1904, p. 182; 1906:472. R.B. 35, p. 266. Gn. 69, p. 71; 71:270. J.H. III. 46:295. G.M. 46:163; 49:141. F.S.R. 2:168.—One of the best introductions of recent years; stands some frost. It blooms in early spring, the season lasting two months or more. Not hardy north of Washington, but nearly evergreen in the S.

BB. *The lvs. alternate: fls. yellow.*

19. **frùticans,** Linn. (*J. lùteum*, Gueld. *J. syrìacum*, Boiss. & Gaill.). Glabrous bush, to 12 ft., not climbing,

but with slender and weak branches which are angled: lvs. alternate; lfts. 3 (rarely 1), somewhat curved, obovate to spatulate or oblong, obtuse: fls. yellow, not fragrant, few in subterminal clusters; calyx-lobes subulate; corolla-tube twice length of calyx, about ½in. long; lobes of corolla 5, obtuse: berries black at maturity. S. Eu., N. Afr. B.M. 461.—Evergreen.

20. **hùmile,** Linn. (*J. revolùtum,* Sims. *J. Wallichiànum* Lindl. *J. flàvum,* Sieb. *J. triúmphans,* Hort.). Fig. 2009. A diffuse shrub, in the open ground in the S. reaching 20 ft. and requiring support, but in glasshouses usually grown as a pot-bush: branches glabrous, angled: lvs. alternate, odd-pinnate (rarely reduced to 1 lft.), the lateral lfts. 1–3 pairs, all lfts. thickish and acuminate, and more or less revolute on the edges, varying from oblong to oblong-lanceolate to oblong-rotund: fls. bright yellow, in open clusters; calyx-teeth very short; corolla-tube ¾–1 in. long, usually considerably exceeding the mostly obtuse and reflexing lobes. Trop. Asia. B.M. 1731. B.R. 178; 350; 1409. L.B.C. 10:966.—Apparently the commonest jasmine in American glasshouses, usually known as *J. revolutum.* It is hardy in the open as far north as Maryland. Lvs. thick and evergreen. Needs a cool house if grown under glass. Summer and fall bloomer. *J. Reèvesii,* Hort., probably belongs to this species. Some horticulturists distinguish a *J. humile* from *J. revolutum,* the former said to be of smaller size, less floriferous, and fls. smaller and scarcely fragrant.

2009. **Jasminum humile.** (×⅓)

21. **pubígerum,** D. Don. Erect shrub, much like *J. humile* and perhaps a form of it, but softly and densely villous: lvs. alternate; lfts. 3–7, to 2 in. long, suborbicular to ovate or oblong, villous on both surfaces: fls. yellow, in dense nearly sessile, very villous, about 15-fld. cymes; calyx-teeth linear, longer than in *J. humile;* corolla-tube ⅔in. long. India.

22. **odoratíssimum,** Linn. Much like No. 20, but more erect and less leafy when in flower: lvs. alternate, the lfts. 3 or 5, shining, oval or broad-oval and obtuse: fls. yellow, in a terminal cluster; calyx-teeth very short; corolla-lobes oblong-obtuse, mostly shorter than the tube. Summer. Madeira. B.M. 285.—It is an erect, glabrous shrub with straight, stiff, terete or slightly angular branches.

23. **flóridum,** Bunge (*J. subulàtum,* Lindl.). Shrub, glabrous, erect but with flexuous branches: lvs. alternate, 3-foliolate (rarely 5-foliolate), the lfts. coriaceous, ovate-oblong or oval and acute: fls. golden yellow, ½in. diam. in open cymes or panicles; calyx-teeth long-subulate, as long as the tube, the calyx-tube turbinate and 5-angled; corolla-tube 4 times length of calyx; segms. ovate, acute, spreading to 1¾ in. across; stamens included. China. B.M. 6719.—Hardy as far north as Washington. Apparently very little planted.

J. auriculàtum, Vahl. Scandent, pubescent or nearly glabrous: lvs. mostly simple but sometimes 3-foliolate and the lateral lfts. reduced to auricles: fls. white, in compound many-fld. cymes; corolla-tube ½in. or less long, the lobes elliptic and ¼in. long. India. B.R. 264.—*J. calcàreum,* Muell., is a spring- and summer-blooming Australian twining quite glabrous species with white fls. and simple, opposite, thick, 3- or 5-nerved lvs.—*J. dídymum,* Forst. Climber: fls. small, white, in narrow axillary cymes which exceed the lvs.: lvs. opposite, ternate; lfts. often retuse. Austral. B.M. 6349. Said to be an excellent warmhouse species.—*J. Giráldii,* Diels. Branches angled, hairy: lvs. alternate, 3–5-foliolate; lfts. lanceolate, somewhat obtuse or apiculate, the terminal one longer: corymb terminal, about 3–5-fld.; calyx-segms, subulate, hispid; corolla yellow, the tube 6–8 times longer than calyx, the lobes apiculate. China. Allied to J. humile and J. pubigerum.—*J. paniculàtum,* Roxbg. Evergreen climber, suitable for warmhouse: lvs. opposite, 3 foliolate; lfts. elliptic, obtuse: fls. white, in cymes; corolla-tube ½in. long. China. B.R. 690. L.B.C. 5: 469.—*J. polyánthum,* Franch., a Chinese species in the way of J. grandiflorum, may be expected to appear in cult. in greenhouses. Fls. white inside, reddish outside, long-tubed, very fragrant: lvs. opposite, with about 5 long-acuminate lfts: sts. long and sarmentose. R.H. 1891, p. 270.

L. H. B.

JATEORHÌZA (name alludes to healing qualities of the root). Also spelled *Jatrorrhiza. Menispermàceæ.* Tropical twiners.

Herbaceous perennials or suffrutescent, with rough or setose sts.: lvs. large, palmately lobed: diœcious; male fls. in long and slender racemose panicles in the axils; female fls. in racemes that are simple or nearly so; sepals 6 in 2 series; petals 6, shorter than the sepals; stamens (in male fl.) 6, the filaments free or connate; carpels (in female fl.) 3, with divided stigmas: fr. an ovoid drupe.—Species apparently 2, in Trop. Afr. *J. palmàta,* Miers (*Cócculus palmàtus,* DC. *Menispérmum palmàtum,* Lam. *M. Colúmba,* Roxbg. *J. Colúmba,* Miers). Probably not in the trade in our territory, but the fascicled fusiform fleshy roots are the source of the drug calumba: st. herbaceous: lvs. 6–16 in. across, 3–5-lobed, deeply cordate, the lateral lobes broad-ovate or roundish triangular, the central lobe often broadly obovate: male panicles very slender, 6–12 in. or more long: drupes ovoid, setose, in clusters of 4–6. Mozambique; the name calumba or columba is said to have come from Columbo, Ceylon, whence the supply of roots was once supposed to have come. B.M. 2970, 2971.

L. H. B.

JÁTROPHA (Greek, referring to its medicinal use). *Euphorbiàceæ.* A varied group of tropical herbs, shrubs or trees; several species cultivated in the greenhouse for their ornamental or curious leaves and flowers; and some grown in the tropics for their economic uses.

Juice milky: lvs. alternate, simple, usually palmately lobed, sometimes pinnate and entire: fls. monœcious, rarely diœcious, usually with petals; sepals 5, more or less connate at base, imbricate; stamens about 10, in 2 or more whorls, some, at least, with the filaments connate; ovary 2–5-celled, 1 ovule in each cell: fr. a caps.—About 150 species, chiefly in the tropics of Amer. and Afr. Related to Hevea and Aleurites.

Most of the species of Jatropha are tropical shrubs, but several low or herbaceous species extend into the southern United States. One, the spurge nettle, *J. stimulosa,* Michx. (*Cnidoscolus stimulosus,* Gray), is a stinging weed of sandy soil in the South, with white tubular calyx. A related species *J. aconitifolia,* is planted for hedges in Central America. Many species have found use in medicine chiefly as local or popular remedies. The oil of *J. Curcas,* for which the plant is cultivated in tropical America, is used as a purgative and also for cooking, soap-making and the like. In Mexico the seeds are reported to be eaten like peanuts. A few years ago *J. gossypifolia* attracted some attention as a remedy for leprosy.

Most of the species are adapted to sandy loam soil. They grow readily from seeds, and cuttings from hard young branches can be rooted in sand with bottom heat if dried somewhat before bedding.

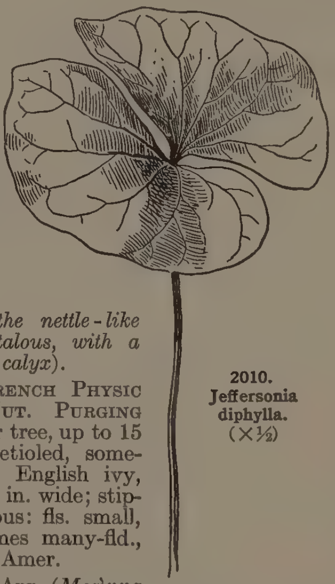
A. *Petals free, or nearly so: lvs. long-petioled; stipules usually dissected and persistent.*

gossypifòlia, Linn. BELLYACHE BUSH. Subshrub, 2–6 ft. high: lvs. 5-lobed, nearly glabrous, 4–6 in. wide, with prominent gland-tipped hairs on the margin, stipules and petioles, those of the latter branched: petals dark purple; ovary pubescent: fr. globular-oblong, warty. Trop. Amer., Key West; Trop. Afr. L.B.C. 2:117. B.R. 746.

glandulífera, Roxbg. (*J. glaùca,* Vahl). Shrub, 3–4 ft. high: lvs. 3–5-lobed, almost glabrous, glaucous, glandular dentate; stipules nearly 1 in. long; petiole not glandular: fls. yellowish green; ovary glabrous. India.

multífida, Linn. Coral Plant. Physic Nut. Shrub, 5–15 ft. high: lvs. deeply palmately 7–11-parted, glabrous, glaucous below, the lobes narrow, 4–7 in. long, pinnately incised to entire; stipules about ½in. long; petiole not glandular: fls. scarlet. Texas to Brazil.

podágrica, Hook. Guatemala Rhubarb. Physic Nut. Tartago. Shrub, 1–2 ft. high: lvs. peltate, 3–5-lobed, 4–8 in. wide, glabrous and glaucous, lobes entire; stipules about ¼in. long; petiole not glandular: petals scarlet; ovary glabrous. Cent. Amer. H.F. 8:146. B.M. 4376.



2010. Jeffersonia diphylla. (×½)

pandurifòlia, Andr. (*J. acuminàta,* Desv. *J. hastàta,* Griseb. *Mánihot diversifòlia,* Sweet). Large shrub: lvs. ovate to oblong or panduriform, entire except the dentate base, 2–3 in. wide, glabrous or puberulent; petiole 2 in. or less long; stipules small, entire, not glandular: petals over ½in. long, scarlet; cyme many-fld. W. Indies. B.M. 604. L. B. C. 17: 1604.

AA. *Petals united (the nettle-like species are apetalous, with a tubular petaloid calyx).*

Cúrcas, Linn. French Physic Nut. Barbados Nut. Purging Nut. Large shrub or tree, up to 15 ft. high: lvs. long-petioled, somewhat 3–5-lobed like English ivy, almost glabrous, 3–6 in. wide; stipules minute; deciduous: fls. small, yellowish green; cymes many-fld., corymbiform. Trop. Amer.

spathulàta, Muell. Arg. (*Mozìnna spathulàta,* Ort.). Tocote Prieto. Shrub, 1–15 ft. high, stoloniferous: branches fleshy: lvs. sessile, nearly glabrous, spatulate, entire or 3-lobed: fls. in fascicles, diœcious, pale rose-color; ovary 1–3-celled: caps. usually 1-seeded. Texas to Cent. Amer.—Sometimes seen in succulent collections.

J. aconitifòlia, Mill., var. *Papàya,* Pax. Tree, apetalous, stinging, spiny. Cent. Amer.—*J. canéscens,* Muell. Arg. Shrub: petals united. Calif. to Cent. Amer.—*J. fràgrans,* HBK. Tree, stinging, spiny, apetalous: fls. aromatic. Cuba.—*J. integérrima,* Jacq.= J. diversifolia, Muell. Arg. Small tree or shrub: petals free, stipules entire; fls. red. B.M. 1464. W. Indies.—*J. Kunthiàna,* Muell. Arg. Shrub, apetalous, stinging, spiny. Trop. Amer.—*J. Mánihot*= Manihot.—*J. Pohliàna,* Muell. Arg. Shrub or small tree: petals free: stipules dissected. S. Brazil.—*J. ùrens,* Linn. Shrub, stinging, spiny, apetalous. G.C. II. 14:753. Trop. Amer.

J. B. S. Norton.

JEFFERSÒNIA (Thomas Jefferson, third president of the United States). *Berberidàceæ.* Attractive hardy perennial herbs.

Rhizomatous: lvs. radical, palmately nerved, 2-lobed or 2-parted: fl. solitary on a naked scape; sepals 4, petaloid but fugacious; petals 8, flat, larger than sepals; stamens 8, free, with slender filaments; ovary single, the style 2-lobed at apex: fr. a caps., partially circumscissile near summit.—Two species, 1 in E. N. Amer. and 1 in Manchuria. The oriental species, *J. dubia,* Benth. & Hook., seems not to be in cult.

diphýlla, Pers. (*Podophýllum diphýllum,* Linn. *J. binàta,* Bart.). Fig. 2010. Twin-leaf. Rheumatism-root. Lvs. glaucous beneath, 3–6 in. long, 2–4 in. wide, the petioles 6–12 in. high: fls. about 1 in. across, white. N. Y. and Ont. to Wis. and Iowa, and to Tenn. G. 35:113.—A very attractive woods plant. Sometimes has parts of fls. in 3's or 5's. L. H. B.

JERUSALEM ARTICHOKE: *Artichoke, Jerusalem.* **J. Cherry:** *Solanum Pseudo-capsicum.* **J. Cross:** *Lychnis chalcedonica.* **J. Oak:** *Chenopodium Botrys.* **J. Sage:** *Phlomis fruticosa.* **J. Thorn:** *Parkinsonia aculeata.*

JESSAMINE: *Jasminum officinale* and others. **Cape J.:** *Gardenia jasminoides.* **Malayan J.:** *Rhyncospermum jasminoides.*

JEWEL WEED: *Impatiens aurea* and *I. biflora.*

JIMPSON or JIMSON WEED: *Datura.*

JOANNÈSIA (from Johannes). *Euphorbiàceæ.* A tree cult. in many tropical lands for ornament, for the wood, and the seeds used in medicine. Juice milky: lvs. alternate, long-petioled, digitately 3–7-foliate; lfts. stalked, entire: fls. monœcious, with petals; calyx 5-toothed, valvate; stamens 7–10, more or less united; ovary 2-celled, ovules 1 to each cell: fr. a large drupe.—One species, related to Aleurites and Jatropha. It grows easily on poor soil and stands long droughts well. It is hardy in S. Calif.

prínceps, Vell. (*Ánda Gomèsii,* Juss.). Anda Assu and various other native names. A large tree: lfts. ovate, 3–4 in. long: infl. a paniculate cyme, terminal and axillary; fls. inconspicuous: fr. 4–5 in. thick, coconut-like, with 4 large oily seeds. S. Brazil.

J. B. S. Norton.

JOB'S TEARS: *Coix Lacryma-Jobi.*

JOE-PYE WEED: *Eupatorium purpureum.*

JOHNSON-GRASS: *Holcus halepensis.*

JONQUIL: *Narcissus.*

JOVELLÀNA (*Jovellanos,* Spanish personal name). *Scrophulariàceæ.* A half-dozen South American and New Zealand plants that sometimes are included with Calceolaria, are referred to this genus. None of them is apparently in cultivation in this country, but *J. violàcea,* Don (see *Calceolaria violacea,* supplementary list) is sometimes cultivated as a greenhouse plant in the Old World. They differ from Calceolaria in having a ringent corolla without a saccate lip.

JUANULLÒA (George Juan and Antonio Ulloa, Spanish naturalists who traveled in Chile and Peru). *Solanàceæ.* About 10 species of shrubby plants, more or less epiphytic, from Cent. Amer. to Peru, sometimes mentioned in horticultural literature as suitable for growing in the warmhouse. Erect or diffuse and producing runners or decumbent branches, glabrous or tomentose: lvs. thick and entire: fls. yellow or red, solitary or in clusters; calyx colored, large; corolla tubular, sometimes ventricose and contracted at the throat, with small broad lobes; stamens inserted in lower part of corolla-tube: fr. an indehiscent succulent or dry berry. *J. aurantìaca,* Otto & Dietr. (*J. parasítica,* Hook.), is the species most likely to occur in cult. It is a glabrous shrub with herbaceous young branches: lvs. alternate, sometimes 2 together and very unequal, 2–5 in. long, oval or obovate, obtuse, short-petioled: fls. terminal on drooping branches in a sort of leafy raceme, showy, orange; calyx fleshy and large, 5-angled, loose on the corolla, the latter about a third longer and tubular, enlarging upward, and with a limb of 5 short rounded segms. Peru, where it is said to be epiphytic; but said to thrive well in a warmhouse in earth. B.M. 4118. H.U. 2, p. 321. L. H. B.

JUBÆA (after Juba, king of Numidia). *Palmàceæ.* The wine palm of Chile, *J. spectabilis*, which in this country is cultivated outdoors in southern California and in the North under glass.

Jubæa has only 1 species, a tall, unarmed S. American palm: caudex thick, covered with the bases of the sheaths: lvs. terminal, pinnatisect; segms. spreading, linear-lanceolate, rigid; margins recurved; rachis laterally compressed, convex on the back, acute beneath; sheath short, open. Allied genera in cult. are Attalea, Cocos, Maximiliana and Scheelea, which are distinguished chiefly by the staminate fls. In Jubæa the petals are lanceolate; stamens numerous, included, the anther-cells connate: fr. 1-seeded. In Attalea the petals are lanceolate; stamens 10–24, included, anther-cells connate: fr. 2–6-seeded. For distinctions from other genera consult also *Cocos, Maximiliana* and *Scheelea.*

Jubæa spectabilis is a handsome and satisfactory palm for the cool palm-house, where it would be treated in common with such plants as *Chamærops humilis*, the sabals and *Euterpe montana*, which may be grown well in a night temperature of 50°, providing the plants are properly established. In general appearance, *J. spectabilis* reminds one of some kinds of Phœnix, and, like them, does not show the true character of its foliage in a very small state, the seedling jubea producing several simple leaves before developing foliage of the pinnate type. In Jubæa, however, the lower pinnæ do not revert to spines, as is usually the case with Phœnix and the pinnæ are also arranged irregularly on the midrib, thus giving the fronds a feathery effect. The culture of jubea is by no means difficult, propagation being effected by means of imported seeds, which usually give a fair percentage of germination, providing they are started in a warmhouse and kept moist. The seedlings should be potted as soon as the second leaf appears, and kept in a warmhouse until they are large enough for a 4-inch pot, and from this time forward cooler treatment will give the best results, always remembering the fact that while many palms (and jubea among the number) will bear much neglect, yet the best results are to be had only by giving plenty of nourishment. (W. H. Taplin.)

spectàbilis, HBK. Height 40–60 ft. but much lower in cult.: lvs. 6–12 ft. long. G.C. II. 18:401; III. 18:516. Gn. 5, p. 413. V. 8:340. A.F. 22:696. C.L.A. 2:19. Gng. 12:658.—The southernmost American palm. "It is one of the hardiest palms," says Franceschi, "and can endure drought and many degrees of cold. If liberally treated, it makes a large tree in a few years." A full-sized trunk yields about 90 gallons of sugary sap, which is boiled by the Chileans and called "Miel de Palma" or palm honey, which is extensively used on ships and hotels on the west coast of S. Amer. There is some danger of the species being exterminated in Chile. The frs. look like diminutive coconuts, and are called Coquitos, or by the trade "monkey's coconuts." In Europe, it is cult. under glass, and also used for subtropical bedding. N. TAYLOR.†

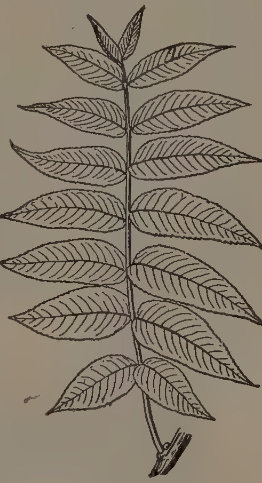
JUBÙBA, Jujuba: *Zizyphus.*

JUDAS TREE: *Cercis.*

JÙGLANS (ancient Latin name from *Jovis glans*, nut of Jupiter). *Juglandàceæ.* WALNUT. BUTTERNUT. Plate LX. Woody plants grown for their handsome foliage and some species for their edible nuts.

Deciduous trees, rarely shrubs: branches with lamellate pith: lvs. alternate, without stipules, odd-pinnate, of aromatic fragrance when bruised: staminate fls. with a 2–5-lobed perianth and 6–30 stamens, in slender catkins; pistillate fls. in few- to many-fld. racemes; ovary inferior, 1-celled, with 4 calyx-lobes and included in a 3-lobed involucre: fr. a large drupe with a thick, indehiscent husk; nut 2- or 4-celled at the base, indehiscent or separating at last into 2 valves.—About 15 species in N. and S. Amer. and from S. E. Eu. to E. Asia; 44 species have been distinguished and described in a monograph by Dode (B.S.D. 1906: 67–97; 1909: 22–50, 165–215, with many illustrations).

The walnuts are usually tall broad-headed trees with large leaves, and with small greenish flowers, the staminate in pendulous slender often conspicuous catkins, the pistillate inconspicuous followed by a greenish large drupe containing an edible nut. Most of the species are hardy, and are very valuable park trees, with a massive, straight trunk, and a light and airy broad top, the best being probably *J. nigra*, one of the noblest trees of the American forest. *J. regia, J. rupestris*, and *J. cathayensis* are hardy as far north as Massachusetts, while *J. californica* is tender in the North. Though many fungi and insects prey on the walnut, none of them does very serious damage, the worst being, perhaps, the hickory-borer. The wood of the walnut, which is easily worked and susceptible of receiving a beautiful polish, is much used for cabinet making and the interior finish of houses, especially that of *J. nigra* and *J. regia*, which is heavy, strong and durable, and of dark brown color, while that of *J. cinerea* and *J. Sieboldiana* is light and soft. The husks of the nuts are sometimes used for dyeing yellow, and the bark for tanning leather. The husk of *J. cinerea* has some medicinal properties. The nuts of all species are edible, and are an article of commercial importance, especially those of *J. regia*, which are the best. This species is extensively grown in the warmer parts of Europe, in California and in the East from Pennsylvania to Georgia. The nuts of the native species are also sold on the market, but mostly gathered in the woods, though a number of improved varieties are in cultivation. *J. Sieboldiana* and var. *cordiformis*, with nuts superior to those of the native species, and much valued in Japan, will probably become valuable nut trees where *J. regia* is too tender; also *J. regia* var. *sinensis* is hardier than the type.



2011. Leaf of Juglans nigra.

The walnut grows best in moderately moist, rich soil, but *J. cinerea* is more moisture-loving and *J. regia* prefers well-drained hillsides. They are not easily transplanted when older, and therefore the nuts are often planted where the trees are to stand, but they may be safely transplanted when two or three years old, or even later when they have been transplanted in the nursery. Propagation is by seeds, which should be stratified and not allowed to become dry. A light, sandy soil is to be preferred, as the young plants produce more fibrous roots, while in stiff soil they are liable to make a long taproot. The young seedlings are transplanted when about two years old; sometimes the taproot is cut by a long knife. Varieties are often grafted on potted stock in the greenhouse in early spring or are budded in summer, either shield- or flute-budding being employed; even top-grafting of old trees is sometimes practised. For culture and further information, see United States Department of Agriculture, "Nut Culture in the United States," quoted below as U. S. N. C.; see, also, *Walnut.*

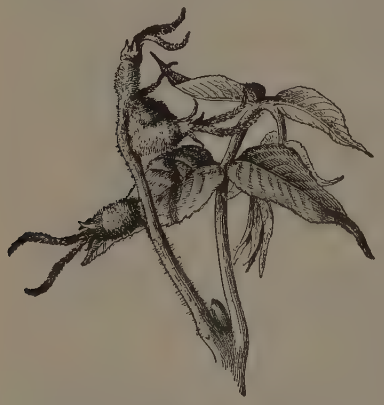
A. *Fr. glabrous or finely pubescent, 1–3; nut 4-celled at the base.*

B. *Lfts. usually 7–9, almost entire.*

1. **règia,** Linn. PERSIAN OR ENGLISH WALNUT. Round-headed tree, to 70 ft.: lfts. 5–13, oblong or oblong-ovate, acute or acuminate, almost glabrous, bright green, 2–5 in. long: fr. almost globular, green; nut usually oval, reticulate and rather smooth, rather thin-shelled. S. E. Eu. Himalayas, China. U. S. N. C. pl. 6. H.W. 2:36, pp. 87–9. M.D. 1911, p. 197 (habit). Many varieties are cult. as fr. trees, for which see *Walnut.* Var. **sinénsis,** DC. (*J. sinénsis,* Dode). Lfts. usually 5, larger, pubescent on the veins below: nut globose-ovoid, very rugose. China, Japan. S.I.F. 2:5. Of the ornamental varieties the most distinct and decorative is var. **laciniàta,** Loud. (var. *filicifòlia,* Hort. var. *asplenifòlia,* Hort.), with narrow, pinnately cut lfts.; very effective as a single specimen on the lawn; remains usually shrubby. M.D.G. 1908:617. Var. **monophýlla,** DC., has the lvs. simple or 3-foliolate. Var. **péndula,** Kirchn., has pendulous branches. Var. **fértilis,** Kirchn. (var. *fruticòsa,* Dipp. var. *præpartùriens,* Hort.), is a shrubby variety producing rather small, thin-shelled nuts on very young plants. Var. **Bartheriàna,** Carr. (var. *elongàta,* Hort.). Nut elongated, narrow-oblong. R.H. 1859, p. 147; 1861, p. 427. Gn. 50, p. 478. Var. **corcyrénsis,** Sprenger. Lvs. large, to 2 ft. long; lfts. 9, the lowest pair very small, the upper pairs broadly ovate, about 8 in. long and 5 in. broad: nut rather thick-shelled. *J. Duclouxiàna,* Dode, from the Himalayas and W. China with more elliptic and more acuminate lfts. and nuts with thin fragile shell, is probably only a variety of *J. regia.*



2012. Pistillate flowers of Juglans cinerea. (Natural size.)

BB. *Lfts. 9–25.*

C. *Width of lfts. usually less than 1 in.*

D. *Nuts deeply grooved.*

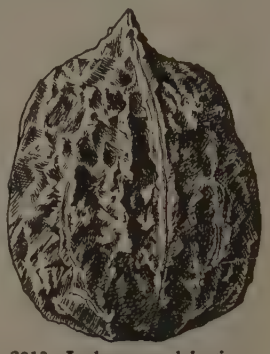
E. *Diam. of nut up to 1½ in.: lfts. 9–13.*

2. **màjor,** Heller (*J. rupéstris* var. *màjor,* Torr. *J. Tórreyi,* Dode). Tree, to 50 ft., with narrow head: branchlets pubescent while young: lfts. 9–13, rarely to 19, oblong-lanceolate to ovate, acuminate, cuneate or rounded at the base, coarsely serrate, soon glabrous or slightly pubescent on the midrib beneath, 3–4 in. long, the lowest lfts. 1½–2 in. long: stamens 30–40: fr. subglobose or ovoid, 1–1½ in. across, covered with a close rufous tomentum; nut dark brown or black, slightly compressed, with broad deep longitudinal grooves, with a thick shell and small sweet kernel. New Mex., Ariz., Colo. S.S. 7:336.

EE. *Diam. of nut not more than ¾in.: lfts. 11–23.*

3. **rupéstris,** Engelm. Shrub or small tree, rarely to 30 ft.: branchlets pubescent when young: lfts. 17–23, narrow-lanceolate, acuminate, finely serrate or nearly entire, puberulous or pubescent when young, at maturity quite glabrous or pubescent on the midrib beneath, 2–3 in. long: stamens about 20; ovary pubescent or tomentose: fr. globular, rarely ovoid, often pointed, usually pubescent, ½–¾in. across; nut with deep longitudinal grooves, thick-shelled, with small kernel. Texas and N. Mex. S.S. 7:335. G.W. 11, p. 399.

4. **califórnica,** Walt. Shrub or tree, 12–20, rarely 40–50 ft. high: branchlets puberulous: petioles glandular-pubescent; lfts. 11–15, rarely to 19, oblong-lanceolate, usually acute, or acuminate, cuneate or rounded at the base, glabrous, 1–2½ in. long: stamens 30–40: fr. globose, ⅓–¾in. across, puberulous, husk thin; nut nearly globose with deep longitudinal grooves. S. Calif. S.S. 7:337, figs. 1–4.



2013. Juglans mandshurica. (Natural size.)

DD. *Nut obscurely or not at all grooved, up to 2 in. across.*

5. **Hìndsii,** Sarg. (*J. califórnica* var. *Hìndsii,* Jepson). Rounded-headed tree, 30–40, occasionally to 75 ft. high, with tall trunk: branchlets densely pubescent at first: petioles villous; lfts. 15–19, usually 19, ovate-lanceolate to lanceolate, long-acuminate, usually rounded at the base, coarsely serrate, pubescent beneath on the midrib and veins, 2½–4 in. long: stamens 30–40: fr. globose, 1¼–2 in. across, soft-pubescent; nut nearly globose, faintly grooved, with thick walls. Cent. Calif. S.S. 7:337, figs. 5–8. Gn. 49, p. 278.—A graceful ornamental tree often planted as a street tree in Calif. and used as stock for grafting varieties of the English walnut. The nut is of good quality, but rather small. Var. **quércina,** Sarg. (*J. califórnica quércina,* Babcock. *J. quercifòlia,* Pierce). An abnormal form with 1–5 lfts., usually 3, short-stalked or sessile, broadly ovate to oblong, obtuse or emarginate, serrate or entire, ½–2 in. long. Jepson, Silv. Calif., pp. 51–3.

CC. *Width of lfts. 1 in. or more: nut prominently and irregularly ridged.*

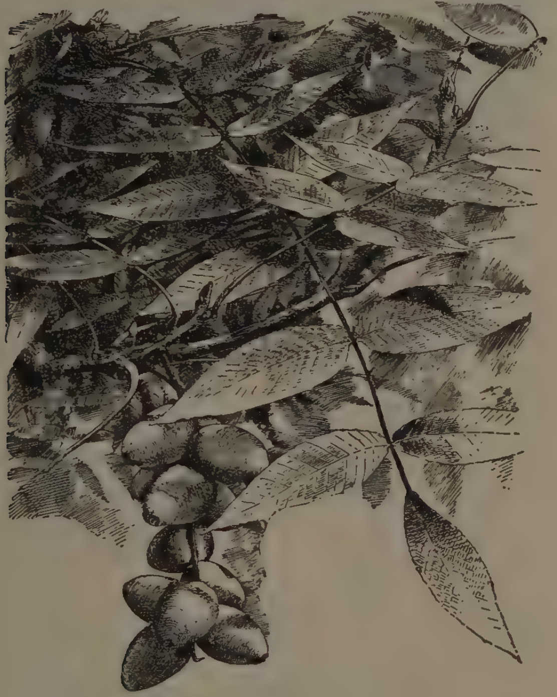
6. **nìgra,** Linn. BLACK WALNUT. Fig. 2011. Lofty tree, to 150 ft., with rough brown bark and pubescent branchlets: lfts. 15–23, oblong-lanceolate, acuminate, appressed-serrate, glabrous and somewhat shining above at length, pubescent beneath, 3–5 in. long: fr. usually 1–3 on a short stalk, 1½–3 in. across, with papillose surface; nut thick-shelled, globular or somewhat depressed, strongly ridged. Mass. to Fla., west to Minn. and Texas. S.S. 7:333, 334. Em. 211. G.C. II. 11:373; 26:617; III. 30:303. F.S.R. 3:210. H.W. 2, p. 182. U. S. N. C. 7, pp. 1–3. Gn. 27, pp. 269, 270. —*J. ovoìdea,* Dode, is a form with ovoid pointed nuts.

AA. *Fr. coated with viscid hairs, racemose; nut 2-celled at the base: lfts. with stellate and glandular pubescence beneath, serrate.*

B. *Nut strongly 6–8-ridged.*

7. **cinèrea,** Linn. BUTTERNUT. WHITE WALNUT. Fig. 2012. Large tree, occasionally to 100 ft., with

gray bark: young branchlets villous and glandular: lfts. 11–19, oblong-lanceolate, acuminate, appressed-serrate, usually pubescent on both sides, more densely below: 3–5 in. long: fr. in short racemes, 2–5, oblong, pointed, 3–5 in. long; nut oblong, with 4 more and 4 less prominent irregular ribs and many broken sharp ridges between. New Bruns. to Ga., west to Dak. and Ark. S.S. 7:331, 332. Em. 207. U. S. N. C. 7, p. 4. Gn. 22, p. 251.



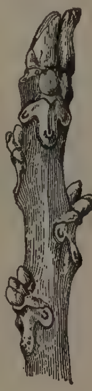
2014. Juglans Sieboldiana. (×⅕)

8. **cathayénsis,** Dode (*J. dracònis,* Dode). Tree, to 70 ft.: branchlets glandular-hairy: lvs. up to 3 ft. long; lfts. 9–17, obovate-oblong, acuminate, obliquely rounded or subcordate at the base, serrulate, sparingly hairy above, more densely below, midrib glandular, 3–9 in. long: fr. 6–10 in pendulous racemes, ovate, pointed, 1¼–1¾ in. long; nuts ovoid, pointed, 6–8-angled, with sharp and broken, nearly spiny ridges. Cent. and W. China. G.C. III. 50:189.—Has proved hardy at the Arnold Arboretum.

9. **mandshùrica,** Maxim. Fig. 2013. Broad-headed tree, to 60 ft.: branchlets glabrescent: lfts. 11–19, oblong, acute, obtusely serrate, at length almost glabrous above, pubescent beneath, rarely almost glabrous at length, 3–8 in. long: fr. in short racemes, globular-ovate to oblong; nut with 8 prominent obtusish ridges. Mandshuria, Amurland. G.C. III. 4:384; 30:302. A.G. 1891:178. R.H. 1861, p. 429 (as *J. regia octogona*). Gn. 50, p. 478 (by error as *J. regia cordata*). U.S.N.C. 7, p. 5.

BB. *Nut rugose or nearly smooth.*

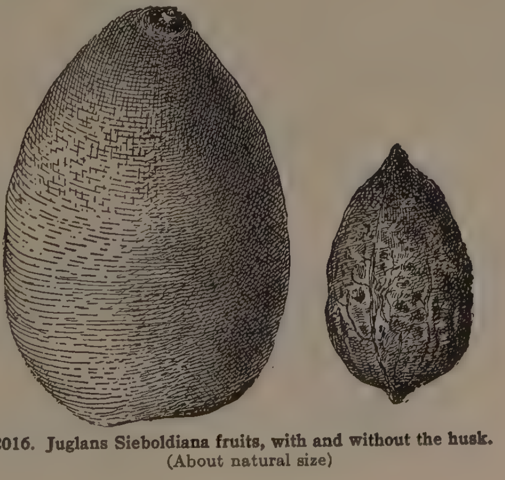
10. **Sieboldiàna,** Maxim. (*J. ailantifòlia,* Carr.). Figs. 2014–2016. Broad-headed tree, to 50 ft.: branchlets pubescent: lfts. 11–17, oval to oval-oblong, short-acuminate, densely serrate, glabrous above, pubescent and usually glandular beneath, 3–6 in. long: frs. in long racemes, sometimes 20, globose to ovate-oblong; nut more or less globose, with thick, wing-like sutures and pointed apex, the surface rather smooth, slightly rugose and pitted, 1–1½ in. long, rather thick-shelled. Japan. Gn. 47, p. 442. A.G. 1890:701; 1891:179. R.H. 1878, pp. 414, 415. U.S.N.C. 7, p. 7. S.I.F. 2:5. Var. **cordifórmis,** Makino (*J. cordifórmis,* Maxim.). Fig. 2017. Nut heart-shaped or ovoid, much flattened, sharply 2-edged, smooth and with a shallow longitudinal groove in the middle of the flat sides, rather thin-shelled. G.C. III. 30:292. S.I.F. 1:17. U.S.N.C. 7, p. 6.—Though this form is very different in its fr. from the true *J. Sieboldiana* there are no other reliable characters to distinguish it, and seedlings raised from nuts of var. *cordiformis* have always produced, at least to a large percentage, trees bearing nuts like those of *J. Sieboldiana* or of intermediate character. Probably *J. Lavállei,* Dode (L.I. 1, 2), is such an intermediate form. *J. coarctàta,* Dode, is another of these intermediate forms with a somewhat longer nut slightly constricted about the middle. *J. subcordifórmis,* Dode, is hardly different from the variety except in its shorter and broader nuts. *J. Allardiàna,* Dode, is probably only a form of the species; it differs little from it except in the gray or blackish dull color of the nut, which is yellowish and lustrous in typical *J. Sieboldiana.*



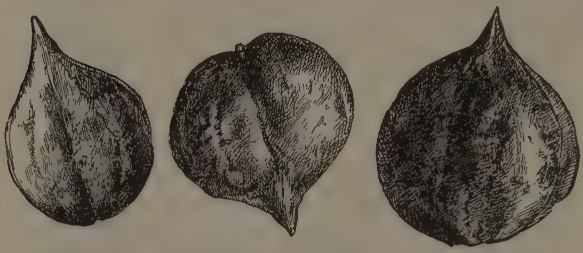
2015. Winter twig of Juglans Sieboldiana.

11. **intermèdia,** Carr. (*J. nìgra* × *J. règia*). Intermediate between the parents, but in general appearance more like *J. regia.* Lfts. usually 11, ovate or elliptic-ovate, remotely denticulate, glabrous dark green. In regard to the fr. 2 forms have been distinguished. Var. **pyrifórmis,** Carr., with an obovoid fr. more resembling that of *J. regia.* R.H. 1863, p. 30. Gn. 50, p. 478. Var. **Vilmoreàna,** Carr. (*J. Vilmorinidàna,* Vilm.). Fig. 2018, with a fr. more like that of *J. nigra.* G.F. 4:52, 53 (adapted in Fig. 2018). M.D. 1911:197.—Probably also *J. regia gibbosa,* Carr., with a large, thick-shelled deeply rugose nut belongs here. R.H. 1861, p. 428. Gn. 50, p. 478. Of the same parentage is without doubt the so-called James River hybrid (Forest Leaves 2:133, 134).

12. **quadrangulàta,** Rehd. (*J. alàta,* Schelle. *J. intermèdia quadrangulàta,* Carr. *J. intermèdia alàta,* Carr. *J. cinèrea* × *J. règia*). Fig. 2019. Tall tree, in its bark, winter-buds and foliage much resembling *J. regia:* lfts. usually 9, oval to oblong, obscurely and remotely serrate, slightly pubescent beneath: fr. sparingly produced, subglobose, about 2 in. long; nut ovoid-oblong, acute at the apex, 1¾ in. long, with deeply sculptured walls thinner than those of the butternut



2016. Juglans Sieboldiana fruits, with and without the husk. (About natural size) and broad ridges at the sutures. Originated in France and in several places near Boston and probably elsewhere. G.F. 7:435 (adapted in Fig. 2019). R.H. 1870, p. 494. Gn. 50, p. 478.—The form figured by Carriere seems much nearer to *J. cinerea*, while the form originated near Boston is more similar to *J. regia*.



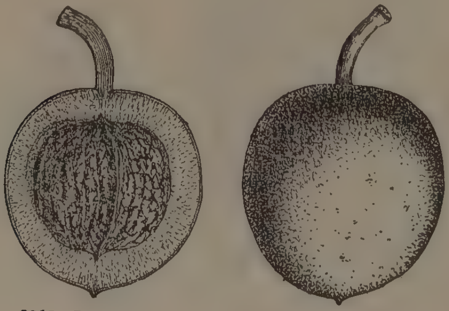
2017. Juglans Sieboldiana var. cordiformis. (Natural size)

Besides these described above, several other hybrids have been reported. Luther Burbank raised a hybrid between J. Hindsii and J. nigra, named "Royal," with large nuts of excellent flavor, and one between J. Hindsii and J. regia, named "Paradox," a very vigorous grower, but a shy bearer. There are supposed hybrids between J. mandschurica × J. regia, J. cinerea × J. nigra and J. cinerea × J. rupestris; J. longirostris, Carr. (R. H. 1878, p. 53), may be a hybrid between J. regia and J. major, which often has a fr. similar in shape to the one figured.—*J. austràlis*, Griseb. Allied to J. rupestris. Lfts. 13–21, large, ovate-oblong, abruptly acuminate, serrate, viscid-pubescent: nut ovoid, acute, small, slightly grooved. Argentina.—*J. collápsa*, Dode. Allied to J. mandschurica and probably only a variety, but nut less rugose, less sharply angled, with ovoid depressions. Probably from N. China.—*J. kamaònia*, Dode (J. regia var. kamaonia, DC.). Allied to J. regia. Lfts. 5–11, oblong-elliptic to oblong-lanceolate, puberulous on both sides, rufous-pubescent on the veins beneath: nut globose, rather hard-shelled. Himalayas. —*J. stenocárpa*, Maxim. Closely allied to J. mandschurica. Lfts. narrower, more coarsely serrate, more pubescent, the terminal lft. very large: fr. more oblong, less strongly ridged. Manchuria.

Alfred Rehder.

JUJÚBE: *Zizyphus Jujuba.*

JULIÀNIA (Julian Cervantes). Doubtfully associated with the *Anacardiàceæ*, but now made the type of the family *Julianiàceæ*. Tortuously branched resinous diœcious shrubs or small trees of Mex., perhaps not in cult.: lvs. alternate, unequally pinnate, the lfts. 3–11: fls. small, green; male fls. and infl. much like those of the oak, "a single, hairy, thin perianth, divided nearly to the base into 5 or 7 acute segms., with as many stamens alternating with the segms."; female fls. 2–4 in an involucre, the whole having the appearance of a single fl., of curious structure: fr. composite, dry, with an exceedingly hard involucre, indehiscent, germination taking place through the apex. The known species are 4, one of which, *J. adstríngens*, Schlecht., is figured in G.C. III. 43:99, by Hemsley (adapted from Trans. Roy. Soc. of London). Aspect somewhat like some species of Rhus: lfts. 5–7, sessile or the terminal very short-stalked, 1–1½ in. long, obovate or oval, dentate: fr. 2 in. long, enlarging upward. *J. Huaucùi*, Gray, of Peru, is referred to Orthopterygium; probably not in cult.



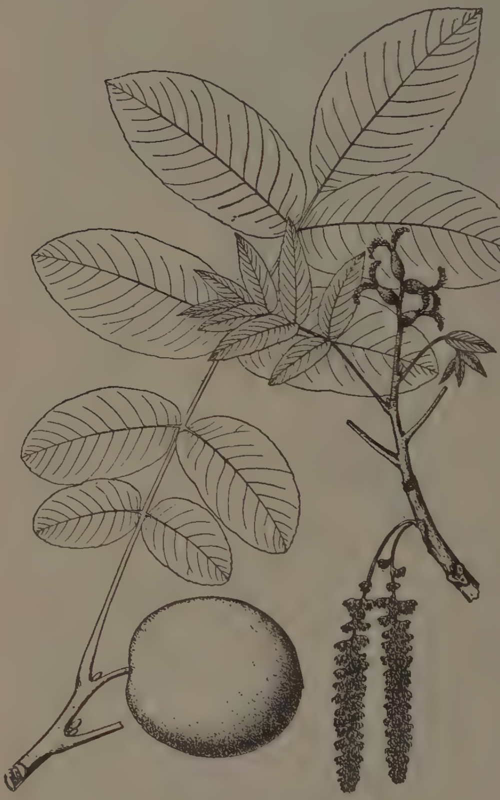
2018. Juglans intermedia var. Vilmoreana. (×½)

JÚNCUS (classical name, *to join*). *Juncàceæ*. Rushes. Grass-like plants growing in wet, rarely in dry, places and used for planting in bogs and around aquatic gardens.

Plants send up from the rootstock several unbranched cylindrical sts. which bear a terminal, or sometimes apparently lateral, cyme of greenish or brownish very small fls.: lvs. grass-like terete or flat: perianth of 6 rigid chaffy parts in 2 whorls; stamens short, either 3 or 6: caps. 3-celled or rarely 1-celled, many-seeded. Rushes differ from the true grasses and sedges in having a true perianth and a many-seeded pod.—The genus includes a host of species distributed throughout the temperate regions, but most of these are not in cult. Rushes are sold by dealers in native and aquatic plants. The kind used in making mats in Japan is procurable from dealers in Japanese plants.

A. *St. without lvs.: cymes apparently lateral.*

effùsus, Linn. (*J. commùnis*, Hort.). Common Rush. Fig. 2020. St. soft, 1–4 ft. high: cyme diffuse, 1–2 in. long, the fls. separate; sepals acute, equaling the short retuse and pointless or mucronate greenish brown caps.; stamens 3: seeds not tailed. North Temperate Zone. Used also for weaving into mats, and the like. Var. **compáctus**, Lej. & Coutt. (var. *congéstus*, Hort.). Fls. small, ¾–1½ lines long: cyme congested into a spherical head: culms rather stout, finely many striate. Much of the *J. conglomeratus* of the trade is probably this variety. Var. **conglomeràtus**, Engelm., is similar to the last, but the culm coarsely few (12–15) striate, and perianth very dark. Var. **solùtus**, Fern. & Wiegand. Fls. medium, 1½–2½ lines long; perianth semi-appressed: cyme open: culms coarse with usually pale basal sheaths, at least when dry. Var. **Pỳlæi**, Fern. & Wiegand. Fls. medium; perianth spreading:



2019. Juglans quadrangulata. (×⅓)

cyme open: culm medium, usually coarsely striate at least when dry: basal sheaths usually dark. Var. **vittàtus**, Buch. (*J. effùsus* var. *aùreo-striàtus*, Hort. *J. conglomeràtus* var. *variegàtus*, Hort.). Foliage striped with yellow. Var. **spirâlis**, Hort. Fig. 2021. A curious form with sts. spirally twisted like a corkscrew. Gt. 54, p. 406.

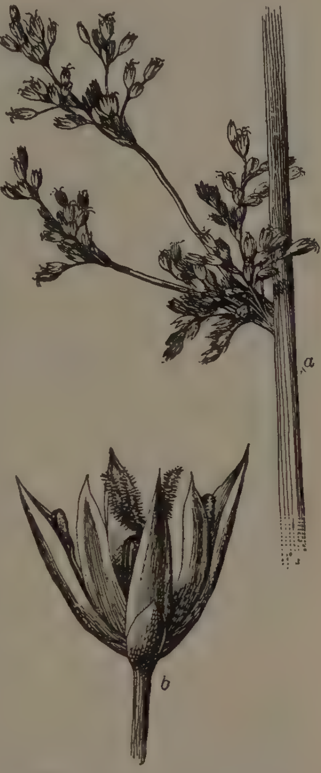
AA. *St. bearing terete lvs.: cyme terminal, open, but fls. borne in heads at end of branches.*

canadénsis, Gay. Sts. 1½–3 ft. high, tall and coarse: heads numerous; stamens 3: seeds long-tailed at each end. N. Amer.

nodòsus, Linn. Sts. lower, ½–1½ ft. high: heads few; stamens 6: seeds without tails. N. Amer.—May be used for gravelly borders of pools.

J. acuminàtus, Michx., and other species may be used for water-gardens.—*J. zebrinus*, Hort.=Scirpus Tabernæmontanus var. zebrinus.

K. M. Wiegand.



2020. Common rush, Juncus effusus. The flower-cluster, *a*, is natural size. The single flower, *b*, is enlarged.

JUNEBERRY. Fig. 2022. Fruits of species of Amelanchier.

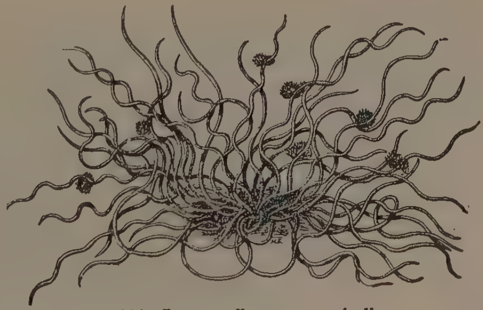
The fruits of some twenty-five or thirty species of Amelanchier are edible, those of several species being especially juicy, sweet and refreshing. Under the names juneberry, shad-bush, service-berry, sugar-pear and grape-pear, or their equivalents in other languages, the wild fruits are used for food in all parts of the North Temperate Zone. The product of one or another of the species plays an important part in the diet of North American Indians, who make use of the berries both fresh and dried. So, also, juneberries have been a source of food-supply to explorers, prospectors and pioneers, who testify to their value as nourishing esculents and pleasing dessert fruits. Juneberries are as yet little used where they must compete with other fruits, although they have many qualities to commend them for domestication.

The fruit of the juneberry is a small pome or apple, usually with five cells each more or less completely divided into two parts so that there appear to be ten cells. The seeds are small and thin-shelled, varying in number from five to ten. The pomes of some species are no larger than a pea, while in the best strains of other species they attain the size of a small crab-apple. They vary in color from dark red to a purplish blue or black and all have more or less bloom. The fruits resemble somewhat the pomes of the hawthorn, for which they are often mistaken. The juneberry, however, is superior to the more common hawthorn as a food product because the flesh is greater in quantity and is not so dry and mealy, the flavor is sprightlier and the seeds are fewer, smaller and thinner-shelled. The several juneberries are quite as variable in the character of their fruits, either within or between species, as are other members of the rose family to which Amelanchier belongs—sufficiently variable to suggest high potentialities in the domestication of the best of the wild species.

Juneberries differ much in the character of the plants. Some species are dwarf shrubs with many stems, while others are small trees with straight, slender trunks, the largest of which attain a height of 40 feet and a diameter of 8 or 10 inches. All of the species are vigorous and the American juneberries are hardy, at least two of them giving promise of making most desirable domesticated plants in regions too cold for any or but few other fruits. Juneberries are easily transplanted and respond to culture as readily as any other species of the rose family. In the garden, they thrive under the same care as that given the apple or pear. Insects and fungous troubles are not particularly apparent in wild species but it is probable that under artificial conditions juneberries would suffer from about the same insects and fungi that attack other pomes. Birds, especially the robin, take heavy toll and would prove troublesome to cultivated plants. The genus shows wide adaptation to soils and moisture conditions, there being few localities in temperate regions where other fruits are grown upon which some one or several of the juneberries would not thrive.

All of the plants in this genus, whether shrubs or trees, have value as ornamentals. The common juneberry of eastern America is a particularly beautiful plant in early spring, bearing large white flowers in profusion, which are well set off by the opening foliage and bright silky bud-scales and bracts. The trees are attractive ornamentals in fruit though the eastern juneberry is often infertile and sets few or no pomes. Trained as a tree or as a many-stemmed shrub, the several juneberries are all desirable lawn and park ornamentals.

From time to time strains of wild species have been brought under cultivation, some of which have been named and sparingly disseminated by nurserymen. So far all of the cultivated varieties have come from the bush-like species, most of them said to be from *A. alnifolia*. One of the first named varieties was Success, a dwarf strain probably of *A. canadensis*, introduced by H. E. Van Deman, then of Kansas, about 1878; this variety seems to be no longer cultivated. Several western nurserymen now offer strains of dwarfs under the names Improved Dwarf Juneberry, Dwarf Mountain Juneberry, and Western Huckleberry. So far as their history can be learned, all these named varieties are selected strains from wild plants, no one as yet having set out to breed and improve juneberries. There are many distinct forms in the wild, some of them supposed to be natural hybrids, offering opportunities for selection in the amelioration of the species for the garden. There is no reason to believe that the species will not hybridize as freely as other members of the rose family. All looks to be favorable for the domestica-



2021. Juncus effusus var. spiralis.

tion of juneberries,—opportunities awaiting a man to do the work.

Juneberries are readily propagated from seeds and no doubt all would yield to budding, grafting and to the same treatment in the nursery given to apples and pears. Some of the species would, no doubt, vex the souls of cultivators by throwing up many suckers, but in garden culture this could be remedied by working on a non-suckering stock. Juneberries are said to be easily budded on the hawthorn. The suckers are commonly used in propagating the species used as ornamentals.

2022. Juneberry. A cultivated form, probably a hybrid between Amelanchier lævis and some other species.

The eleven species described under Amelanchier all have horticultural possibilities well indicated in the descriptions. The species giving greatest promise for their fruits are *A. alnifolia*, *A. lævis*, *A. sanguinea*, *A. stolonifera* and *A. humilis*. To these should be added *A. canadensis* as the most desirable juneberries for ornamentals.

U. P. Hedrick.

JUNÍPERUS (ancient Latin name). *Pinàceæ*. Juniper. Ornamental trees and shrubs grown for their foliage and habit.

Evergreen, with the branchlets spreading in all directions: lvs. either all needle-shaped and in 3's, or needle-shaped and scale-like, and usually opposite, often found on the same plant, the needle-shaped lvs. prevailing on younger plants and vigorous branches, the scale-like ones on older plants: fls. diœcious, rarely monœcious; staminate yellow, consisting of numerous anthers united into an ovoid or oblong catkin; pistillate greenish, minutely globular, with several bracts, each or some bearing 1 or 2 ovules; the bracts become fleshy and unite into a berry-like cone, usually wholly inclosing the 1–6, rarely 12, seeds. The fr. ripens either the first year, as in *J. virginiana*, or the second, as in *J. Sabina* and most species, or in the third, as in *J. communis*.—About 40 species distributed throughout the extra-tropical regions of the northern hemisphere, in Amer. south to Mex. and W. India. Juniperus is closely allied to Cupressus, and sometimes hard to distinguish without fr.; but young plants with needle-shaped lvs. can be almost always told apart, since Juniperus has whitish lines or marks on the upper surface of the lvs., while the similar juvenile forms of allied genera have the whitish marks beneath. Most species are very variable, as well in habit as in the shape of the lvs., which renders the determination of an unknown form, at least without fr., a rather difficult task.

The junipers vary greatly in habit from tall pyramidal trees to low prostrate or trailing shrubs, and have small needle-shaped or scale-like foliage, insignificant flowers and small berry-like fruits usually bluish black and often glaucous, less often brown or orange. Many of the species are hardy North, as *J. virginiana*, *J. scopulorum*, *J. communis*, *J. rigida*, *J. Sabina*, *J. chinensis*, *J. Pseudo-sabina*, *J. sphærica*, *J. squamata;* others are half-hardy, as *J. Oxycedrus*, *J. macrocarpa*, *J. recurva*, *J. excelsa*, *J. occidentalis*, while some, as *J. procera*, *J. Lucayana*, *J. thurifera* and the Mexican species, can only be grown South. All are valuable ornamental plants, and the erect-growing species, mostly of pyramidal or columnar habit, are decorative as single specimens on the lawn or if planted in groups. Some varieties form a very narrow column, and are valuable for formal gardens; the columnar form of *J. virginiana* is a good substitute in the North for the classical cypress. The low prostrate junipers, as *J. communis* var. *montana*, *J. horizontalis*, *J. Sabina*, and *J. squamata*, are well adapted for covering rocky slopes or sandy banks. The close-grained, fragrant wood is much used for the interior finish of houses and in the manufacture of small articles, also for posts, since it is very durable in the soil; that of *J. virginiana* and *J. Lucayana* is in great demand for pencil-making. The fruits and also the young branchlets of some species contain an aromatic oil used in medicine. The fruit of *J. drupacea* is edible.

The junipers thrive best in sandy and loamy, moderately moist soil, but grow well even in rather dry, rocky and gravelly ground. They prefer sunny, open situations. They are well adapted for hedges and for planting as shelter or windbreaks; also for seaside planting. Propagation is by seeds, which germinate usually the second and sometimes the third year; to hasten their germination, they may be plunged for 3 to 6 seconds in boiling water, but this should be regarded as an experiment and tried only with a portion of seed. They are also increased by cuttings of nearly ripened wood in fall under glass, either outdoors or in the greenhouse. As a rule, those with needle-shaped leaves root much more easily than those with scale-like leaves, and the latter are therefore mostly increased by side-grafting during the winter in the greenhouse on young potted plants of the typical form or an allied species. The shrubby species, especially *J. Sabina*, are also propagated by layers.

A. *Foliage always needle-shaped and in 3's, rigid, jointed at the base: fls. axillary, diœcious: winter-buds with scale-like lvs. (See also Nos. 7 and 8.)*

B. *Fr. large, ¾–1 in. across, with the seeds connate into a usually 3-celled bony stone. (Caryocedrus.)*

1. **drupàcea,** Labill. Pyramidal tree with narrow head, to 45 ft.: lvs. lanceolate, spiny-pointed, ½–¾in. long and ⅛–⅙in. broad (the broadest of all species), with 2 white lines above: fr. bluish black, edible. S. E. Eu., W. Asia. G.C. 1854:455; III. 19:519. R.H. 1854, p. 165; 1904, pp. 357, 358.

BB. *Fr. smaller; seeds not connate, usually 3. (Oxycedrus.)*

C. *Lvs. with 2 white lines above.*

2. **macrocárpa,** Sibth. (*J. neaboriénsis,* Gord.). Shrub or small tree, to 12 ft., of dense pyramidal habit: lvs. crowded, linear-lanceolate, spiny-pointed, spreading, ½–¾in. long: fr. to ½in. across, dark brown, glaucous. Medit. region.

3. **Cèdrus,** Webb & Berth. (*J. péndula,* Loud.). Tree, to 12 ft., with pendulous branches; the trunk to 3 ft. diam.: branchlets bluish green, angled: lvs. very crowded, curved or straight, spreading, linear-lanceolate, acute or obtusish, scarcely spiny, ¼–½in. long: fr. subglobose, ⅓–½in. long, bluish at first, finally orange-brown, 1-seeded. Canary Isls. Antoine, Cupressineen Gatt. 19.—Cult. in Calif. The abnormal development of thickness in comparison to height is one of the peculiarities of the species.

4. **Oxycèdrus,** Linn. Bushy shrub or small tree, to 12 ft., with rather slender branches: lvs. linear, spiny-pointed, spreading, ½–¾in.: fr. globose, ¼–⅓in. across, brown, shining, not or slightly glaucous. Medit. region. H.W. 1, p. 193.

CC. *Lvs. with 1 white line above.*

5. **rígida,** Sieb. & Zucc. Small, pyramidal tree, to 30 ft., or spreading shrub with the slender branches pendulous at the extremities: lvs. in closely set whorls, narrow-linear, stiff, yellowish green, ½–1 in. long: fr. about ¼in. across, dark violet. Japan. S.Z. 125. S.I.F. 1:12.—Graceful, hardy shrub, somewhat similar to *J. communis* var. *oblonga,* but the lvs. more crowded and stiffer.

6. **commùnis,** Linn. Common Juniper. Upright shrub or tree, sometimes attaining to 40 ft.: lvs. linear or linear-lanceolate, concave and with a broad white band above, spiny-pointed, ½–¾in. long: fr. almost sessile, dark blue, glaucous, ¼–⅓in. across. Arctic N. Amer. south to Pa., Ill., and in the Rocky Mts. to N. Mex., N. and Cent. Eu. and N. Asia. H.W. 1:10.—A very variable species; some of the most important varieties are the following: Var. **aùreo-variegàta,** Hort. Upright form, with the tips of the branchlets golden yellow. Var. **depréssa,** Pursh (*J. commùnis* var. *canadénsis,* Loud. *J. canadénsis,* Burgsd. *J. nàna canadénsis,* Carr.). Fig. 2023. Forming broad patches, the sts. ascending from a procumbent base, rarely exceeding 4 ft. in height. The lvs. somewhat shorter and broader. Var. **aùrea,** Hort. (*J. nàna* var. *canadénsis aùrea,* Beissn. *J. canadénsis aùrea,* Hort.). Like the former, but tips of branchlets golden yellow. Gng. 5:67. Var. **hemisphærica,** Parl. (*J. hemisphærica,* Presl). A low, dense, rounded bush, rarely more than 3 ft. high: lvs. straight and stiff, short. Mountains of S. Eu. and N. Afr. Var. **hibérnica,** Gord. (var. *strícta,* Carr.). Narrow, columnar form, with upright branches, deep green, tips of branchlets erect. G. 4:521. Gng. 1:355. Var. **montàna,** Ait. (*J. commùnis nàna,* Loud. *J. nàna,* Willd. *J. alpìna,* S. F. Gray. *J. sibírica,* Burgsd.). Low, spreading or procumbent shrub, seldom over 2 ft. high: lvs. oblong-linear, abruptly pointed, usually incurved, densely clothing the branches, with a broad silvery white line above, ¼–½in. long. Arctic and mountainous regions. H.W. 1:10. M.D.G. 1910:123. Var. **Jáckii,** Rehd. Prostrate, with flagelliform trailing branches often to 3 ft. long, and almost unbranched except for occasional clusters of short lateral branchlets 1–2 in. long: lvs. linear-lanceolate, incurved. Ore., N. Calif. Var. **oblónga,** Loud. (*J. oblónga,* Bieb.). Upright shrub, with slender, diverging and recurving branches: lvs. thin, long-attenuate, horizontally spreading, bright green. Transcaucasia. Var. **oblóngo-péndula,** Carr. (var. *refléxa,* Parl.). Similar to the preceding, but more decidedly pendulous. A very graceful form. C.L.A. 11:308. Var. **péndula,** Carr. Shrub, with spreading, recurving branches and pendulous branchlets. Var. **suècica,** Loud. (var. *fastigiàta,* Hort.). Narrow, columnar form, growing sometimes into a tree to 40 ft. high, with rather long, spreading lvs., the branchlets with drooping tips: of lighter and more bluish color than the similar var. *hibernica.*

2023. Juniperus communis var. depressa.

AA. *Foliage usually of 2 kinds of lvs. (Fig. 2025) usually opposite, decurrent: fls. terminal: no distinct winter-buds. (Sabina.)*

B. *Lvs. in 3's, lanceolate, short, loosely appressed: fr. oblong.*

7. **recúrva,** Ham. (*J. repánda,* Hort.). Shrub or small tree, to 30 ft., with spreading and usually recurving branches: branchlets slender: lvs. crowded, curved, appressed, linear-lanceolate, pointed, grayish or glaucous green with a whitish band above, ⅙–¼in. long: fr. olive-brown or blackish purple, when fully ripe, about ¼in. long, 1-seeded. Himalayas. G.C. II. 19:468. Gn. 22, p. 107; 36, p. 215. Var. **dénsa,** Carr. Dwarf, with short, crowded branchlets: lvs. curved, grayish green.

8. **squamàta,** Lamb. (*J. recúrva* var. *squamàta,* Parl. *J. recúrva* var. *dénsa,* Hort.). Decumbent shrub, sometimes ascending: branchlets thick, ascending at the apex: lvs. crowded, loosely appressed, linear-lanceolate or lanceolate, straight or slightly curved, grayish or bluish green, with 2 grayish white bands above: fr. bluish black, globose-ovoid, ¼–⅓in. across. Himalayas, W. China. Var. **Fárgesii,** Rehd. & Wilson. Tree, to 70 ft.: lvs. longer and narrower, linear-lanceolate, more spreading, usually about ⅓in. long, acuminate: fr. ovoid, ¼in. long. W. China. It has proved hardy at the Arnold Arboretum.

BB. *Lvs. mostly opposite, scale-like or of 2 kinds, usually with a gland on the back: fr. mostly globular.*

C. *Fr. erect or nodding: mostly trees.*

D. *Color of fr. reddish brown, with rather dry, fibrous flesh: lvs. minutely denticulate.*

9. **phœnícea,** Linn. Shrub or small tree, to 20 ft., with ovate-pyramidal head and upright branches: branchlets slender: lvs. acicular and spreading or scale-like, imbricate, rhombic, obtuse, opposite, often bluish green: fr. ⅓–½in. across, shining, with 3–6 seeds. S. Eu., N. Afr. Canary Isls. H.W. 1, p. 194. M.D. 1911, pp. 286, 287 (habit).

10. **califórnica,** Carr. Fig. 2024. Pyramidal tree, to 40 ft., or shrub with many erect branches: branchlets rather stout: lvs. usually in 3's, imbricate, rhombic, obtuse, thick, yellowish green, with conspicuous gland, only on vigorous branches acicular: fr. ¼–⅓in. long, with bluish bloom and with 1–2 large seeds. Calif. S.S. 10:517. R.H. 1854, p. 353. A.G. 1890:10.

DD. *Color of fr. bluish black or blue, with juicy, resinous flesh.*

E. *Imbricate lvs. usually in 3's, minutely denticulate.*

11. **occidentàlis,** Hook. Tree, to 40 feet, rarely to 60 ft., with spreading branches forming a broad, low head, or shrub with several upright sts.: branchlets stout and thick, imbricate, ovate, acute, grayish green, rarely acicular: fr. subglobose or ovoid, ¼–⅓in. long, with 2–3 seeds. Wash. to Calif. S.S. 10:521.

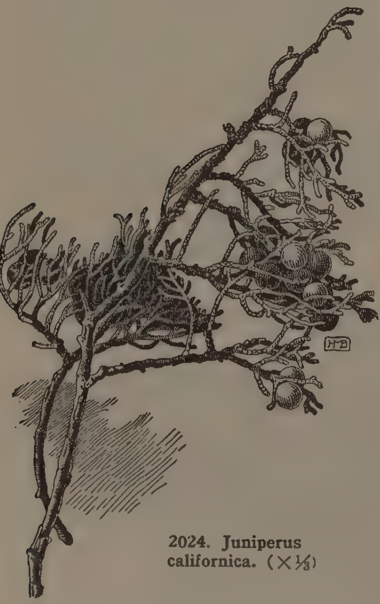
EE. *Imbricate lvs. opposite, entire or nearly so.*

F. *Seeds of fr. 2–6.*

G. *Point of imbricate lvs. acute: branchlets slender.*

12. **excélsa,** Bieb. Tree, to 60 feet, with pyramidal head and upright or spreading branches: lvs. ovate, spreading, mostly opposite, but in 3's on the lower branches, rhombic, bluish green: fr. bluish black, bloomy, globular, about ⅓in. across, with 3–6 seeds. Greece, W. Asia to Himalayas. Gt. 46, p. 209. Var. **stricta,** Hort. Of upright, columnar habit, with very glaucous foliage. Var. **variegàta,** Carr. Foliage variegated with yellowish white.

13. **pròcera,** Hochst. Tree, to 100 or 150 ft., similar to the preceding: lvs. in 3's, or opposite, lanceolate and spreading or loosely appressed and ovate-lanceolate: fr. globose, small, about ¼in. across, 2–3-seeded. Mountains of E. Afr.—Probably the tallest species of the genus.



2024. Juniperus californica. (×⅓)

GG. *Point of imbricate lvs. obtuse.*

14. **chinénsis,** Linn. (*J. sinénsis,* Hort.). Tree, to 60 ft., or shrub, sometimes procumbent: branches rather slender: lvs. opposite or whorled, linear, pointed and spreading, with a white band above or scale-like, appressed, rhombic, obtuse: fr. globular, brownish violet, bloomy, ⅕–⅓in. across, with 2 or 3 seeds. Himalayas, China, Japan. S.Z. 126, 127. S.I.F. 1:12. G.C. III. 42:163. C.L.A. 11:308. G.W. 1, p. 305.—Very variable in habit: the staminate plant usually forms a much-branched, upright, pyramidal bush, often almost columnar, while the pistillate has slender, spreading branches. They are therefore often distinguished as var. **máscula** and var. **fémina** (var. *Reèvesii,* Hort.). The first one is the most desirable as an ornamental plant. Var. **álbo-variegàta,** Beissn. (var. *argéntea,* Hort.). Dwarf, dense form, with dimorphic lvs.: tips of branchlets mostly white. Gn.M. 6:292. Var. **aùrea,** Beissn. (var. *máscula aùrea,* Hort.). Upright form, with the young branchlets golden yellow, the color becoming more brilliant in the full sun. Var. **péndula,** Hort. With spreading branches, pendulous at the extremities. Var. **Pfitzeriàna,** Spaeth. Forming a broad pyramid with horizontally spreading branches and nodding branchlets, grayish green. G.W. 5, p. 403. Var. **pyramidàlis,** Carr. Narrow, pyramidal form, with bluish green, mostly needle-shaped foliage. Var. **procúmbens,** Endl. (*J. procúmbens,* Sieb. *J. japónica,* Carr.). Dense, low shrub with spreading, sometimes procumbent branches and mostly acicular lvs. in whorls, with 2 white lines above, longer and stouter than in the type. S.Z. 127, fig. 3. G.W. 13, p. 618. Var. **procúmbens aùrea,** Beissn. Branches robust and long, decumbent, with rather few branchlets, young growth golden yellow at first, changing to light green. Var. **procúmbens aùreo-variegàta,** Beissn. Dwarf, dense form, variegated with golden yellow.

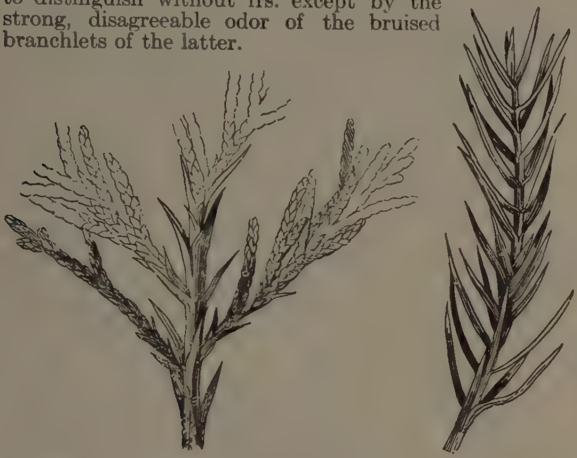
15. **sphærica,** Lindl. (*J. Fórtunei,* Van Houtte). Similar to the former. Densely branched shrub or tree, to 30 ft., with upright branches: branchlets short, rather thick, quadrangular: lvs. acicular and whorled, but less rigid than those of the former, or scale-like, rhombic-oblong, somewhat spreading: fr. globular, about ⅓in. across, not bloomy, 3-seeded. N. China. Probably not specifically different from the preceding species. Var. **glaùca,** Gord. (*J. Shéphardii,* Hort.). Dense form, with usually needle-shaped glaucous foliage.

FF. *Seeds of fr. 1–2; fr. small, ⅙–⅓in. across.*

G. *Trees hardy, sometimes shrubby.*

16. **virginiàna,** Linn. RED CEDAR. SAVIN. Fig. 2025. Tree, to 100 ft., with conical head and spreading or upright branches: lvs. acicular, spiny-pointed, spreading or scale-like, rhombic, acute or subacute, imbricate, very small: fr. brownish violet, bloomy, globular or ovoid. Canada to Fla., east of the Rocky Mts. S.S. 10:524. G.F. 8:65; 10:145. F.E. 27:147. G.W. 16, p. 540.—A very variable species. Some of the most important varieties are the following: Var. **álbo-spicàta,** Beissn. Tips of branchlets white. Var. **álbo-variegàta,** Beissn. Branchlets variegated with white; a very similar more constant form is "Triomphe d' Angers." Var. **aùreo-variegàta,** Hort. With golden yellow variegation. Var. **Cannártii,** Beissn. A compact, ovate-pyramidal form, dark green, with bloomy bluish fr. Var. **Chamberlàynii,** Carr. With spreading branches and elongated, pendulous branchlets: lvs. dimorphic, grayish green. Var. **dumòsa,** Carr. Dense shrub, forming a rounded pyramid, with mostly needle-shaped, bright green lvs. Var. **elegantíssima,** Hort. Tips of young branchlets golden yellow. Var. **glaùca,** Carr. Vigorous-growing form, with glaucous foliage. Var. **globòsa,** Beissn. Compact globose form with bright green scale-like foliage. Var. **péndula,** Carr. With spreading limbs and slender, pendulous branches: lvs. usually scale-like. Var. **plumòsa,** Hort. A graceful pyramidal form with needle-shaped lvs., the tips whitish (var. *plumòsa álba* or *plumòsa argéntea,* Hort.), or pure white (var. *plumòsa nívea,* Schwendt.). Var. **pyramidàlis,** Carr. Dense, columnar form, with the foliage glaucous (var. *pyramidàlis glaùca*) or bright green (var.

pyramidàlis víridis). Var. **réptans,** Beissn. Low shrub, with horizontally spreading, procumbent branches and slender, curving branchlets: bright green. M.D.G. 1896:296. Probably the same as var. *horizontalis,* Arb. Kew. Var. **Schóttii,** Beissn. A dwarfish, dense, pyramidal form, with bright green and rather light foliage. Var. **tripartìta,** Beissn. A dwarf, spreading form of irregular habit, densely branched, with acicular, glaucous lvs. F.E. 33:15. Var. **venústa,** Hort. (*J. venústa,* Ellwanger & Barry). A columnar form with glossy dark green, scale-like foliage.—The dwarf forms are often very similar to *J. Sabina* and hard to distinguish without frs. except by the strong, disagreeable odor of the bruised branchlets of the latter.



2025. The two kinds of red cedar leaves. (Natural size)

17. **scopulòrum,** Sarg. Closely allied to the preceding; chiefly distinguished by the somewhat larger fr., ripening not until the second year; by its habit, forming a broad head with stout, spreading branches and often dividing into several sts. near the base, and by its shredding bark. The branchlets are somewhat shorter and stouter, and the foliage usually glaucous or yellowish green. Brit. Col. to Calif. in the Rocky Mts. G.F. 10:423. S.S. 14:739.

GG. *Trees tender.*

18. **Lucayàna,** Brit. (*J. austràlis,* Pilger. *J. barbadénsis,* Auth. *J. virginiàna* var. *Bedfordiàna,* Veitch, not Linn. *J. virginiàna* var. *barbadénsis,* Gord.). Tree, to 50 ft., with spreading branches and slender pendulous 4-angled branchlets: lvs. light green, closely appressed, ovate, sharp-pointed, glandular: fr. globose, about ⅙in. thick, dark blue, bloomy, 1–2-seeded. S. Ga. to Fla., Jamaica, Cuba, Bahamas, Haiti. S.S. 14:738.—One of the most beautiful of the junipers, often planted for ornament in the Gulf States, and in the W. Indies.

19. **barbadénsis,** Linn. (*J. bermudiàna,* Linn.). Tree, to 40 ft., in habit much like *J. virginiana,* but branches much stouter and foliage pale bluish green: branchlets thickly set, quadrangular, stout and short: lvs. mostly imbricate, thick or acicular, spiny-pointed, rigid, erect-spreading: staminate catkins larger: fr. usually 2-seeded and depressed-globular. Bermuda, Barbadoes, Antigua. G.C. II. 19:657. G.F. 4:295.

CC. *Fr. pendulous, on curved peduncles, small: shrubs, usually spreading or procumbent.*

20. **Sabìna,** Linn. Spreading or procumbent shrub, rarely with erect st. to 10 ft.: branchlets rather slender, of a very strong, disagreeable odor when bruised: lvs. needle-shaped, acute and slightly spreading or imbricate, oblong-rhombic, obtuse or subacute, usually dark green: fr. ⅕–¼in. thick, globular, 1–3-seeded. Mountains of Cent. and S. Eu., W. Asia, Siberia, N. Amer.—Very variable. The most remarkable varieties are the following: Var. **fastigiàta,** Beissn. Erect shrub of columnar habit, with dark green, mostly imbricate lvs. Var. **cupressifòlia,** Ait. (var. *hùmilis,* Endl.). Procumbent, with ascending thickish branchlets: lvs. usually imbricate, scale-like, often bluish green. Var. **tamariscifòlia,** Ait. (*J. sabinoìdes,* Griseb.). Procumbent or ascending, rarely erect: lvs. usually all needle-shaped and often in 3's, slightly incurved, dark and bright green, with a white line above. Mountains of S. Eu. G.W. 1, p. 304. Var. **variegàta,** Beissn. Branchlets variegated with creamy white: lvs. mostly imbricate.

21. **horizontàlis,** Moench (*J. prostràta,* Pers. *J. Sabìna* var. *procùmbens,* Pursh. *J. rèpens,* Nutt.). Procumbent, usually with long trailing branches furnished with numerous short branchlets, sometimes to 4 ft. high and with spreading branches: lvs. of young plants subulate, mature foliage imbricate, scale-like, acute or acutely cuspidate, bluish green or steel-blue: fr. about ⅓in. across, blue, slightly glaucous, on a pedicel shorter than its length. Nova Scotia to Brit. Col., south to Mass., N. Y., Minn. and Mont. B.B. (ed. 2) 1:67. Var. **Doúglasii,** Hort., is a distinctly trailing form with steel-blue foliage, turning purple in autumn with glaucous bloom; also called Waukegan juniper.

J. conférta, Parl.=J. litoralis.—*J. davùrica,* Pall. Allied to J. Sabina. Procumbent, with slender, spreading or drooping branchlets: fr. 1–4-seeded, small. Siberia.—*J. fláccida,* Schlecht. Graceful tree, to 30 ft., with spreading branches and slender, remote, pendulous branchlets: lvs. acute, with spreading tips: fr. globular, 5–10-seeded. Texas, Mex. S. S. 10:519.—*J. fœtidíssima,* Willd. Allied to J. excelsa. To 12 ft. high: branchlets thicker: lvs. with spreading apex, mucronate, usually eglandular: fr. larger, 1–2-seeded. Greece, W. Asia.—*J. formosàna,* Hayata (J. taxifolia Parl., not Hook. & Arn. J. oblongo-pendula, Hort.). Allied to J. rigida. Tree, to 40 ft.: lvs. rigid, spiny-pointed, with 2 white bands above, ½–1 in. long: fr. ovoid, orange, ⅓in. across. Formosa, Cent. & W. China. Has proved hardy at the Arnold Arboretum; the true J. taxifolia, Hook. & Arn. is not in cult.—*J. litoràlis,* Max. (J. conferta, Parl.). Allied to J. rigida, but prostrate, with long, trailing branches: fr. larger. Japan.—*J. macrópoda,* Boiss. Allied to J. excelsa. Shrub or small tree, to 30 ft., sometimes procumbent: lvs. closely appressed: fr. nodding, globular, 4-seeded. Persia to Himalayas.—*J. megalocárpa,* Sudworth. Allied to J. californica. Tree 30–50 ft. with a single trunk: lvs. in 3's, acute: fr. ½in. across or slightly more, 1–2-seeded. Ariz.—*J. mexicàna,* Schiede. Pyramidal tree: branchlets numerous, short and rather stout: lvs. acute, loosely appressed: fr. 2–4-seeded. Mex.—*J. mexicàna,* Schlecht.=J. tetragona.—*J. monospérma,* Sarg. (J. occidentalis var. monosperma, Engelm.). Closely allied to J. occidentalis. Branchlets more slender: lvs. usually opposite and eglandular: fr. smaller and usually 1-seeded. Rocky Mts., from Colo. to New Mex. S.S. 10:522.—*J. oblóngo-péndula,* Hort.=J. formosana.—*J. pachyphlæa,* Torr. Tree, to 60 ft. allied to J. occidentalis, with broad, pyramidal or round-topped head: lvs. usually opposite, glandular, bluish green: fr. dark reddish brown, bloomy, with 3–4 seeds. Has a checkered bark like a black-jack oak. Colo. to Texas and New Mex. S.S. 10:520.—*J. Pínchotii,* Sudworth. Allied to J. californica. Small tree to 20 ft., usually with several sts.: branchlets rather slender: lvs. usually in 3's, appressed, sharply pointed, yellowish green: fr. globose or ovoid, ⅓in. long, red, 1–2-seeded. Texas. B.T. 110.—*J. Pseùdo-sabìna,* Fisch. & Mey. Allied to J. Sabina. Erect shrub, with thick, dense and short branchlets: lvs. usually dimorphic: fr. ovate, blackish, glossy, 1-seeded. Siberia.—*J. sabinoìdes,* Endl.=J. thurifera.—*J. sabinoìdes,* Nees=J. tetragona.—*J. sabinoìdes,* Griseb.=J. Sabina var. tamariscifolia.—*J. saltuària,* Rehd. & Wilson. Allied to J. Pseudo-sabina. Tree to 40 ft.: lvs. dark green, dimorphic, those of the lateral branches scale-like, obtusish, of the shoots in 3's, acute: fr. erect, ovoid, ¼in. long, 1-seeded. N. W. China.—*J. Sánderi,* Hort.=Chamæcyparis obtusa var. ericoides.—*J. taxifòlia,* Parl.=J. formosana.—*J. tetrágona,* Schlecht. Allied to J. occidentalis. Small tree, to 20 ft., rarely to 40 ft., with round-topped or pyramidal head and slender, quadrangular branchlets: lvs. obtuse, usually eglandular: fr. subglobose, mostly 1-seeded. Texas to Mex. S.S. 10:523.—*J. thurífera,* Linn. Shrub or tree, to 40 ft., with round-topped head and spreading branches: branchlets slender: fr. globular, 2–3-seeded. Spain, Algeria.—*J. utahénsis,* Lemm. (J. californica var. utahensis, Engelm.). Bushy tree, rarely more than 20 ft., with broad, open head: branchlets slender: lvs. obtuse, light yellowish green: fr. usually 1-seeded. Colo. to Calif., west to Utah. S.S. 10:518.

ALFRED REHDER.

JURÌNEA (named for Louis Jurine, 1751–1819, professor of medicine). *Compósitæ.* Herbs or subshrubs, one of which is offered for the wild garden: lvs. gray or white-tomentose beneath or on both sides, pinnate or entire, unarmed: fls. purple: achenes 4–5-sided, seldom compressed, crowned with a pappus of unequal rough hairs.—Over 50 species from Cent. and

S. Eu., N. W. Afr., to Cent. Asia. None of the species is of great horticultural value, although sometimes cult. They thrive in any ordinary garden soil and are prop. by seeds or division of the roots in spring. **J. alàta,** Cass. Height 3–4 ft.: perennial, or according to Boissier, biennial: st. erect, winged below, 1–1½ ft. high: radical lvs. 6 in. long, oblong and lyrate, nearly glabrous above and canescent beneath: st.-lvs. lanceolate, sinuate-dentate, decurrent: heads hemispherical, long-peduncled, the involucre-bracts narrow-linear and the outer ones short-mucronulate and the apex spreading; florets purplish blue: achene 4-angled and muricate, the pappus exceeding it. Caucasus. J.H. III. 66:442. While *J. alata* is definitely described as biennial and as reaching a height of 18 in. in cult., the plant grown under this name, and which is apparently correctly determined, is said to be perennial and to grow 3–4 ft. high, having a silvery aspect in the foliage. L. H. B.

JUSSIÆA (Bernard de Jussieu, 1699–1777, who laid the foundations of a modern natural system of the vegetable kingdom). Also written *Jussieua. Onagràceæ.* Primrose Willow. This genus includes one or two herbs that are more or less cultivated, one at least as a water plant.

Herbs, shrubs or even tree-like plants, with alternate usually entire but sometimes serrate mostly narrow lvs., and sometimes more or less showy axillary or solitary white or yellow fls.: calyx tubular with 4–6 acute persistent lobes; petals 4–6, spreading, inserted on margin of the disk; stamens 8–12 in 2 rows, inserted with the petals; ovary 4–5-celled, style simple, stigma 4–6-lobed: fr. a terete, angled or costate, dehiscent, many-seeded caps.—Species about 50, widely distributed in temperate and warm regions, but most abundant in S. Amer.; some are native in the U. S.

The horticultural interest in this genus, in this country, centers about the plant known in the trade as *J. longifolia*, a summer-flowering aquatic herb, and differing somewhat from the botanical description given below. The stems of young seedlings are four-winged, and a specimen before the writer of a plant of the previous season is five-winged. The main root of these old plants may be tuber-like, 3 inches long, ½inch thick, or 8 to 10 inches long and more slender. Also the lower leaves, at least, are opposite.—*J. longifolia* is best treated as a tender annual. The seed may be sown in fall or spring in shallow water, using seed-pans or pots, as with other flower seeds. Cover the seed, which is very fine, with finely sifted soil, place the pot or seed-pan in water, but do not submerge until the second day, when the seed will be thoroughly soaked and will not float on the surface of the water. When the plants attain a few leaves they should be potted, singly, into thumb-pots, and later into 3-inch pots, and from these planted into their summer quarters. It is not absolutely necessary to keep these plants always submerged in water after potting. The plants will do well on a bench, which should be covered with sand or ashes and the plants kept well watered. (Wm. Tricker.)

longifòlia, DC. Erect, glabrous: st. 3-angled: lvs. sessile, lanceolate-linear, acuminate at both ends, glandular beneath at the margins: pedicels 1-fld., longer than the ovary, and bearing 2 bractlets at the apex: petals 4, obovate, scarcely notched at the apex; stamens 8. Brazil.—It is not clear whether this is the plant that is listed as *J. longifolia.*

Sprèngeri, Hort. Evergreen prostrate perennial, somewhat soft-hairy, much branched, the st. winged: lvs. opposite, crowded, ovate and acute: fls. very large, canary-yellow. Argentina.—Offered abroad (Sprenger, Naples); said to be one of the most beautiful aquatic plants and that it grows equally well if grown as a terrestrial subject. L. H. B.†

JUSTÍCIA (James Justice, a Scotch gardener and author of the eighteenth century). *Acanthàceæ.* Greenhouse plants, grown for the showy fascicles, spikes or panicles of white, violet or red bracted flowers.

Mostly herbs of various habit, with opposite entire lvs: calyx deeply divided into 4 or 5 narrow lobes; corolla 2-lipped, the straight or curved tube very short and dilated above, the upper lip erect or incurved and concave and the summit entire or somewhat 2-toothed, the lower lip 3-lobed and spreading; stamens 2 attached in the throat; staminodia none; disk ring-like or cupulate: caps. ovate or oblong, with seeds 4 or less.—Species 250–300, widely distributed in many warm regions, in Amer. reaching as far north as Texas. From Jacobinia, close garden ally, the genus is distinguished by the spurred or appendaged anthers. Justicia is variously understood. Lindau (in Engler & Prantl, Pflanzenfamilien) refers no less than 30 genera to it, among others being Adhatoda and Dianthera. Most of the garden plants known as justicias are jacobinias. Consult Jacobinia, for example, for *Justicia magnifica, J. carnea, J. Pohliana, J. velutina, J. Mohintlii, J. coccinea, J. Ghiesbreghtiana* and *J. Lindenii.* Others may belong to Thyrsacanthus, Dædalacanthus and Schaueria; and there has been confusion even with Whitfieldia.

The remarks on culture under the different species of jacobinias will apply here. Plants are secured readily from cuttings made in late winter or spring, and these should bloom the coming fall or winter. After blooming, discard the plants, except such as are to be kept for furnishing cuttings. Unless well headed back, old plants become loose and weedy, and they take up too much room.

The *Justicia quadrifida* now offered in S. Calif., is probably **Anisacánthus virgulàris,** Nees (*Justícia virgulàris*, Salisb. *J. coccínea,* Cav., not Aubl. *J. quadrífida,* Vahl. *Drejèra pubérula,* Torr.). Plant vigorous, rather straggling, with long erect branches, glabrous: lvs. deciduous, light green, opposite and decussate, elliptic-lanceolate, spreading, rigid: fls. scarlet-red (or orange-scarlet), usually solitary, axillary in one of the 2 opposite axils, thus making a long leafy unilateral spike; corolla-tube long and slender, deeply lobed into 4 spreading or recurved parts. Mex. R.H. 1872:50. Autumn and winter in S. Calif., Aug. and Sept. in France. Var. **compácta,** Franceschi, is a very compact low bush of emerald-green color and covered all summer with orange-scarlet fls.; comes true from seed.—Not to be confounded with *Justicia quadrifaria,* Wall.

Of the justicias appearing in American lists, only **J. furcàta,** Jacq. (*Adhátoda furcàta,* DC.) seems now to be retained in the genus. Herbaceous, pubescent, the st. erect and terete: lvs. oblong-oval, attenuate to petiole: fls. small, in short aggregated axillary spikes which are often geminate, the bracts linear-lanceolate; color of fls. purple and white; upper lip 2-fid, the lower 3-fid and broad-convex. S. Mex.—Said to seed itself freely in S. Calif., but to be of little value.

J. callètricha and *J. calycótricha,* Hort., see Schaueria.—*J. flàva,* Hort., and *J. flavícoma,* Lindl.=Schaueria. L. H. B.

JUTE is a fiber plant, of easy culture in warm climates. It has been successfully grown in the Gulf States, but the want of suitable machines for separating the fiber is the great obstacle which prevents the growth of the jute-fiber industry in America. See *Corchorus;* also "Cyclopedia American Agriculture," Vol. II.

K

KADSÙRA (Japanese name). *Magnoliàceæ.* Tropical Asian woody climbers. Kadsuras have leathery or rarely membranous foliage: fls. axillary, solitary, whitish or rosy, unisexual; sepals and petals 9–15, gradually changing from the outermost and smallest to the innermost and petaloid; staminate fls. with an indefinite number of stamens, which are separate or coalesced into a globe: carpels indefinite in number, 2–3-ovuled: mature berries in globular heads.—About 8 species, of one of which Charles S. Sargent writes (G.F. 6:75): "The flowers are not at all showy, but it is a plant of extraordinary beauty in the autumn when the clusters of scarlet fruit are ripe, their brilliancy being heightened by contrast with the dark green, lustrous, persistent leaves. . . . It might well be grown wherever the climate is sufficiently mild, as in the autumn no plant is more beautiful."

japónica, Linn. Small, procumbent, warty shrub: lvs. oval or oblong-oval, thick, serrate: peduncles 1-fld., solitary. Japan, as far as 35° north latitude.—The type is advertised by Japanese dealers; also a variety with foliage blotched with white, and another with foliage margined white.

2026. Kalanchoe carnea. (Plant × ¼)

KAEMPFÈRIA (Engelbert Kaempfer, 1631–1716, traveled in the Orient, and wrote on Japan). *Zingiberàceæ.* Tuberous- or fleshy-rooted plants, grown for foliage and flowers.

Often stemless or apparently so, the few lvs. aggregated at the base and sometimes distichous on the st.: lvs. mostly broader than lanceolate: fls. in a bracted tuft or small cluster in the center of the lf.-clump, or in a peduncled raceme, often large and showy, white, yellow, violet or purple; calyx cylindrical or funnelform, toothed; corolla tubular, exserted, with narrow lobes; staminodia petal-like and the showy parts, one of them being a broad lip; fertile stamen 1.—More than 50 species in Trop. Asia and Afr. Schumann, Engler's Pflanzenreich, hft. 20 (1904). For cult. see *Hedychium* and *Zingiber.*

A. *Foliage margined with white.*

Gílbertii, Bull. Stemless, fleshy-rooted: lvs. oblong-lanceolate, deep green, bordered white, wavy at the margin: fls. purple and white. E. Indies. G.C. II. 17:713. R.B. 21:169. S.H. 2:131. G.Z. 27, p. 217.—Intro. by W. Bull, 1882. Reasoner Bros. cult. this outdoors in S. Fla., and say, "The fls. are borne on ornamental crimson heads rising from the ground on separate stalks, and resembling in outline small pineapple frs. These heads retain their beauty all summer."

AA. *Foliage not margined with white.*

B. *Lvs. tinged purple beneath.*

rotúnda, Linn. Stemless, tuberous: lvs. not produced until after the fls., oblong, erect, petioled: corolla-segms. long-linear; staminodes oblong, acute, white, 1½–2 in. long; lip lilac or reddish, deeply cut into 2 suborbicular lobes; anther-crest deeply 2-fid: petiole short, channelled; blade 12 in. long, 3–4 in. wide, usually variegated with darker and lighter green above and tinged purple beneath: spikes 4–6-fld., produced in March and April. India. B.M. 920 and 6054. R.B. 25:181.

BB. *Lvs. not tinged purple beneath.*

Kírkii, Schumann (*Cienkówskya Kirkii,* Hook. f.). Lf.-st. 3–4 in. long: lvs. about 4, crowded at the apex of the st., oblong, acute, 8–9 in. long, 2½–3 in. wide at the middle: flowering sts. short, slender, 1-fld.; corolla-lobes oblong-lanceolate, 1 in. long; staminodes more than twice as long as the corolla-lobes, pale rose-purple; lip rounded at the apex, slightly notched, 2 in. broad, with a yellow mark at the throat. Trop. Afr. B.M. 5994. I.H. 30:495. G.W. 2, p. 253. Var. **elàtior,** Stapf. Taller: lvs. longer, the base long-attenuate, the petiole longer: lip bright rose, with a yellow blotch bordered by purple marking. Rhodesia. B.M. 8188.

K. lùtea, C. H. Wright. Stemless: lvs. 3 or 4, about 9 in. long, oblong, green and glabrous above but paler and pilose beneath: scape 3½ in. high; bracts about 8, rounded and green; fls. yellow, the lip entire and orange-yellow. Penang (India).—*K. ròsea,* Schweinf. Much like K. Kirkii, but said to be more beautiful: rootstock short and fleshy, with many cord-like roots: lvs. about 18 in. long, the blade bright green and plaited: scape 18 in. high, bearing about 6 fls. to many, which are above 2 in. across, brilliant rose-red and open one at a time, with an orange-blotched throat. Cent. Afr.

Wilhelm Miller.
L. H. B.†

KAFIR or **K. CORN:** *Sorghum.*

KAGENÉCKIA (F. v. Kageneck, an Austrian minister to Spain). *Rosàceæ.* Very few species of tender small evergreen trees from Chile and Peru, one of which has been grown in S. Calif. but now is probably lost to cult. in this country. The fls. are white, 5-petaled, about ¾in. across, and unisexual. The male fls. are borne in racemes or corymbs; the females are solitary; all are terminal: lvs. leathery, serrate, stalked: stamens 16–20, inserted on the mouth of the calyx, in 1 series: carpels 5, free: ovules numerous.

oblónga, Ruiz & Pav. Lvs. oblong, acuminate at both ends, the serrations obtuse and rather callous. Chile. B.R. 1836 (as *K. cratægifolia*). L. H. B.

KAKI: *Diospyros* and *Persimmon.*

KALÁNCHOË (from Chinese name). *Crassulàceæ.* Sometimes spelled *Calanchoë.* Succulent glasshouse herbs or subshrubs, with interesting foliage and flowers.

Usually robust erect plants: lvs. opposite, fleshy, sessile or stalked, varying from entire to crenate and pinnatifid: fls. yellow, purple or scarlet, in many-fld.

terminal paniculate cymes, rather large and often showy; calyx 4-parted, the narrow lobes shorter than the corolla-tube, usually falling early; corolla 4-parted and mostly spreading, the tube usually urn-shaped; stamens 8: carpels, 4.—More than 100 species, in the Old World tropics and in S. Afr., and 1 reported from Brazil. A few species are prized by amateurs. The fls. are lasting in bouquets. For the general handling of this class of plants, see *Succulents;* also *Cotyledon* and *Crassula.* They prop. readily by seeds and cuttings.

A. *Fls. of the red, scarlet, orange, yellow series.*

coccínea, Welw. Somewhat hairy above, 2–4 ft. tall: lower lvs. ovate, obtuse, coarsely crenate-dentate, stalked; upper lvs. linear-lanceolate, obtuse, sessile: fls. scarlet or orange, on short pedicels, in broad forking panicles which have stalks about 1 ft. long; calyx pubescent, the segms. lanceolate, acute; corolla-tube ½in. long, the limb ½in. across, and the segms. deltoid-ovate, acuminate and glabrous or pubescent. Trop. Afr.

Kírkii, N. E. Br. St. 2–4 ft., simple or branched, more or less glandular-pubescent: lower lvs. soft-fleshy, pubescent, oblong to lanceolate, about 4 in. or less long, the petioles to 2 in. long, irregularly crenate-dentate; uppermost lvs. linear-cuneate, nearly or quite entire: fls. brilliant orange-scarlet, in large corymbose cymes; calyx-lobes or sepals (free to base) oblong, acute, green, glandular-pubescent; corolla-tube ⅓in. long, yellowish green, thinly glandular-pubescent; lobes about ¼in. long, elliptic, scarlet-orange, red on the back. Trop. Afr. R.H. 1914, p. 21. M.D.G. 1908:521.

flámmea, Stapf. A foot to 18 in. high, glabrous, little branching: lvs. ovate-oblong, obtuse, narrowed into a short petiole (blade about 2 in. long and 1¼–1½ in. wide), fleshy, obscurely crenate-dentate or almost entire: fls. yellow and orange-scarlet, ½in. across; calyx parted to the base, the segms. linear-lanceolate and somewhat acute; corolla-tube 4-angled, less than ½in. long, yellowish; lobes ovate-acute, orange-red. Trop. Afr. B.M.7595. G.C. III. 26:47.—Thrives in a comparatively cool greenhouse.

glaucéscens, Brit. St. glabrous, terete, 2 ft. or more, sometimes with long ascending pubescent branches which are nearly leafless below: lower lvs. narrow-ovate, obtuse and irregularly crenate, 5 in. long, narrowed to clasping petioles: infl. glaucous, being a di- or trichotomous panicle; fls. red or dark yellow, sometimes on few-fld. peduncles from the upper nodes; calyx-lobes lanceolate, acute or nearly so, short; corolla-tube ½in. long, bearing short narrow-ovate acute segms. Trop. Afr.

crenàta, Haw. St. glabrous, or somewhat hispid in the upper part, 2–6 ft. high from a thick fibrous root: lvs. oblong or roundish ovate or spatulate, 2–3 in. long, coarsely crenate, obtuse: infl. of many-fld. axillary and terminal cymes; fls. bright yellow or orange; calyx-lobes glabrous or hispid-viscid, lanceolate and acute, only slightly joined at base; corolla-tube ½in. long, glabrous or pubescent; lobes acute, oblong-lanceolate. Trop. Afr. B.M. 1436 (as *Cotyledon crenata*).—*K. crenàta,* Hamet=*Bryophyllum crenatum.*

2027. A Norfolk kale field at the Christmas harvest time.

rotundifòlia, Haw. St. glabrous, slender, 1–3 ft., leafy below: lvs. roundish obovate, obovate or spatulate, nearly entire or crenulate, somewhat petioled, the lower ones 1–2 in. long: infl. of panicled trichotomous flat-topped cymes; fls. orange or deep yellow; calyx small; corolla small (less than ½in. long), the lobes narrow-lanceolate and acute. S. Afr.

AA. *Fls. pink.*

cárnea, Mast. Fig. 2026. Sts. simple, 2 ft. or less, glabrous: lvs. oval or obovate, obtuse, crenate-dentate, narrowed into a short petiole, the upper ones nearly linear and sessile: fls. light rose or pink, very fragrant, nearly ½in. across; calyx parted to the base, the segms linear-pointed; corolla-tube swollen at base and 2–3 times longer than calyx: corolla-lobes broad-oval, acute. S. Afr. G.C. III. 1:211. G.F. 3:53 (reduced in Fig. 2026).—Good winter bloomer, prop. by seeds or cuttings. Seeds sown in spring give blooming plants for following Christmas.

AAA. *Fls. white or white-yellow, very long.*

marmoràta, Baker (*K. grandiflòra,* Rich., not Wight). St. stout and branching: lvs. large (6–8 in. long), obovate, narrowed to a short broad petiole, crenate, blotched with purple: fls. long and tubular (3 in. or more long), creamy white or yellowish, the lobes ovate-acuminate. Abyssinia. B.M. 7333. I.H. 43, p. 45.—Interesting pot-plant, with large trusses of erect fls.

Any number of kalanchoës may appear in the collections of fanciers. Following are some of the more recent kinds, which may not be found in the regular manuals: *K. angolénsis,* N. E. Br. Lvs. fleshy, to 4 in. long and half as broad: fls. bright yellow and numerous, variable in the number of its corolla-lobes. Trop. Afr.—*K. Béntii,* C. H. Wright. St. 3 ft., unbranched, nearly 1 in. diam.: lvs. about 6 pairs near top of st., rigid and subcylindrical, 3–6 in. long: fls. white, in a loose erect panicle; calyx-lobes fleshy and spreading; corolla 1½ in. long, 4-angled, inflated at base, the limb nearly 1 in. across. Arabia. B.M. 7765.—*K. divérsa,* N. E. Br. St. 1½–2 ft. high: lvs. lanceolate to elliptic-ovate, to 5 in. long, toothed, glabrous: fls. with a green tube ½in. long and vermilion-orange shorter lobes. Somaliland.—*K. Dỳeri,* N. E. Br. A fine species, 2–2½ ft. high, glabrous: lvs. elliptic and spreading, 4–7 in. long, coarsely toothed, petiole to 3 in. long: infl. corymbose-cymose, to 1 ft. long; fls. with a pale green tube 1½ in. long, and a pure white spreading limb of lanceolate-acute lobes 1 in. long. Trop. Afr. B.M. 7987.—*K. Elìzæ,* Berger. St. simple, about 8 in.: lvs. oblong, nearly 4 in. long, entire: fls. red, in axillary thyrse-like panicles; corolla almost 2-lipped, the tube nearly 1 in. long, the lobes linear and acute and about ½in. long. Trop. Afr.—*K. felthaménsis,* Hort., is a hybrid of K. flammea and K. Kirkii.—*K. kewénsis,* Hort., is a hybrid of *K.* Bentii and K. flammea.—*K. latisépala,* N. E. Br. Related to K. Dyeri, but lvs. sessile and fls. about half the size: st. about 2 ft.: lvs. obovate, 4–5 in. long: fls. white, in many-fld. terminal cymes; corolla-tube 1¼ in. long; lobes ½in. long, ovate or elliptic-ovate. Trop. Afr.—*K. Lùciæ,* Hamet. St. stout, simple, erect: lvs. sessile, obovate or obovate-spatulate, 1–3 in. long: fls. (color not given) in a panicle-like cluster, the corolla urn-shaped and the segms. shorter than tube. Transvaal.—*K. mágnidens,* N. E. Br. St. 2½ ft. or more, glabrous, green and with no bloom: lvs. petioled, 3½ in. or less long, the lower elliptic-ovate and with 3 or 4 large teeth on either side: infl. loosely branched, the ultimate cymes compact, 9–25-fld.; corolla light salmon, the tube somewhat less than ½ in. long. Uganda (Trop. Afr.).—*K. prasìna,* N. E. Br. Small, with small and not attractive fls.: sts. leafy, about 1½ in. long: lvs. obovate or spatulate-obovate, 2–3 in. long, entire, or obscurely crenate: fls. with a green tube less than ¼in. long, and short white lobes with greenish center. Trop. Afr.—*K. somaliénsis,* Baker. Erect, shrubby: lvs. obovate or oblong-obovate, 4–6 in. long, toothed: fls. in a loose cyme to 10 in. long, white faintly tinged yellow; corolla-tube 2½ in. long; lobes ovate-lanceolate. Somaliland.—*K. sexangulàris,* N. E. Br. St. 6-angled, simple and straight, about 3 ft. high: lvs. stalked, the lower ones elliptic or suborbicular, about 3 in. long: fls. small, yellow, in a panicle about 8 in. long. Probably Transvaal.

L. H. B.

KALE (*Brassica oleracea* var. *acephala*). Figs. 2027, 2028. This plant and the so-called Georgia collard are without doubt more closely akin to the wild cabbage of Europe than any of the other cultivated forms of Brassica. Kale is really a non-heading cabbage. It is hardy and enjoys the cool portion of autumn and early spring for its growth. It ranks low in quality, but because it is hardy and will stand the winters of the Atlantic seaboard states south of New York, it supplies a cheap and palatable pot-herb during the winter season.

2028. Kale.—Leaf of Scotch Curled.

Commercially kale is extensively grown in only two districts, namely, in the vicinity of Norfolk, Virginia, and on Long Island, New York. This restricted commercial area is undoubtedly due to economic rather than soil or climatic conditions. The fact that it is a coarse, light, low-priced commodity in greatest demand from December to April restricts its profitable extensive culture to regions possessing peculiar climatic and transportation conditions,—that is, mild winters, a relatively short haul, and reasonable transportation rates.

There are several forms of kale, but only two are extensively grown for market,—Scotch kale and blue kale. Scotch kale forms by far the greater bulk of the plantings in the Norfolk area, but because the blue kale is considered hardier it is often used for late plantings and by those who have been delayed in seeding their crop.

While kale can be started under cover and transplanted with as great ease and certainty as cabbage, it is seldom handled in this way outside the kitchen-garden. Under field conditions the land is prepared the same as for cabbage, by liberal fertilizing and thorough plowing and harrowing. The seed is usually planted in drills 3 feet apart and later thinned, by chopping out, to a stand of individual plants about 6 inches apart in the row. In the Norfolk area, the seeding is done between August 15 and 20 and if the plants grow vigorously they are often harvested to meet early market demands in such a way as to accomplish the work of further thinning. The main crop is harvested by cutting the thick whorl of leaves that forms the crown of the plant. These are packed for market either in barrel-high Delaware baskets or in veneer barrels. The kale is pressed firmly as it is filled into the receptacle. The barrels are then covered by a clean burlap drawn over the mass piled on top of the barrel and held in place by driving down the loose top hoop.

Kale requires somewhat less fertilizer than cabbage, is less expensive to produce, usually produces an abundant crop which can be harvested at small cost and with a fairly satisfactory net profit an acre. The yields vary from 200 to 400 barrels to the acre with an average of about 250 barrels. The price ranges all the way from 50 cents to $2 a barrel. As usually handled, kale is not at its best. It is not economically possible to produce high-grade kale. Good kale is young tender kale which yields only a small crop to the acre. For the amateur, however, high-quality kale is possible, for he can handle it so as to secure the quick growth of young tender plants, which insures quality. The commercial grower must fill barrels if he is to find profit.

L. C. Corbett.

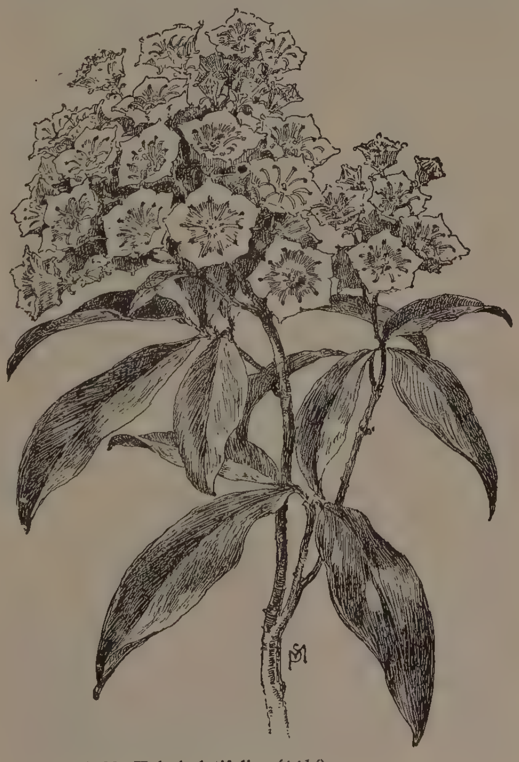
KALE, SEA: *Crambe maritima*, treated under *Sea-Kale*.

KÁLMIA (after Peter Kalm, Swedish botanist, traveled from 1748 to 1751 in North America). *Ericàceæ.* American Laurel. Ornamental shrubs grown for their handsome flowers and foliage.

Evergreen, rarely deciduous: lvs. alternate or opposite, short-petioled, entire: fls. in terminal or lateral corymbs or umbels, rarely solitary; calyx 5-parted; corolla saucer-shaped or broadly campanulate, 5-lobed; stamens 10, with slender filaments, the anthers held back in little pouches of the corolla, springing up suddenly and discharging the pollen if touched; ovary 5-celled, superior: caps. globular, parting into 5 valves, with numerous minute seeds.—Seven species in E. N. Amer. and Cuba. The lvs. of the kalmias are said to be poisonous to animals, especially those of *K. angustifolia*. The fl. of Kalmia is one of those proposed as a national floral emblem, especially on account of the exquisite symmetrical beauty of the single blossom. Kalmia is a purely American genus, but unfortunately it is popularly known only in the eastern states.

The kalmias are medium-sized or low shrubs, very rarely small trees with purple, pink or nearly white, cup-shaped flowers in showy terminal corymbs or in axillary umbels, rarely solitary, followed by small capsular fruits. *Kalmia angustifolia* and *K. polifolia* are hardy North, and also the most ornamental member of the genus, *K. latifolia*, which next to rhododendron is the most beautiful flowering hardy evergreen. Massed in groups or as single specimen on the lawn, it is one of the most decorative plants when covered with its abundant pink flowers. Even small plants produce flowers. The foliage is very decorative, contrasting well with the red and yellowish branches. The species is easily forced and makes a very handsome pot-plant. The other species are pretty border plants for evergreen shrubberies.

The kalmias thrive well in a sandy, peaty or loamy soil, but dislike clay and limestone. They grow almost as well in swamps as in drier locations and prefer partly shaded situations, but thrive well also in sunny places, provided there be sufficient moisture. They require generally almost the same treatment as the hardy rhododendron, but are less particular about soil and



2029. Kalmia latifolia. (×½)

position. Transplanting, if carefully done either early in fall or in spring, is not difficult; a mulching the first season after planting will be of much advantage to keep the roots from drying in summer and from frost in winter. Propagation is usually by seeds sown in sandy, peaty soil in pans or boxes in early spring and kept in a coldframe or greenhouse. The seedlings should be pricked off as soon as they can be handled, and after they are again established gradually hardened off and the following year transplanted in frames or beds outdoors. Varieties of *K. latifolia* are usually increased by side-grafting on seedlings in the greenhouse or by layers, since it grows less readily from cuttings, while the other species may be propagated by cuttings of half-ripened wood under glass.

2030. Kalmia latifolia var. myrtifolia. (×½)

A. *Fls. in umbels or corymbs.*

B. *Lvs. evergreen.*

C. *Branchlets terete: lvs. pale green beneath.*

D. *The lvs. alternate, pointed.*

latifòlia, Linn. MOUNTAIN OR AMERICAN LAUREL. CALICO BUSH. Fig. 2029. Shrub, 4–10 ft. high, rarely tree to 30 ft., with dense, round-topped head: lvs. petioled, alternate or irregularly whorled, oblong or elliptic-lanceolate, acute at both ends, dark green above, yellowish green below, 3–4 in. long: fls. in large, terminal compound corymbs on viscid peduncles; corolla rose-colored to white, with purple markings within, about ¾in. across. May, June. New Bruns. to Fla., west to Ohio and Tenn. B.M. 175. Em. 443. S.S. 5:236, 237. A.F. 13:32. Gng. 1:306; 3:1; 7:289. Gn. 22:6; 27, p. 549; 33, p. 607; 52, p. 77; 61, p. 9. G.M. 51:551. G. 19:708; 21:664; 35:33, 497. F.E. 9:401. C.L.A. 3:181. A.G. 19:465. M.D.G. 1903:576–79. G.F. 3:453. Mn. 3:183. J.H. III. 51:361. Var. **álba,** Bosse. Fls. almost white. Var. **fuscàta,** Rehd. Corolla inside with a broad dark purpish brown band. Var. **myrtifòlia,** Bosse (var. *nàna* or var. *mìnor*, Hort.). Fig. 2030. Lvs. small, 1–2 in. long, deep green, of slow growth, forming a low, dense bush. G.F. 8:317 (adapted in Fig. 2030). R.H. 1883, p. 11. Gn. 29, p. 379; 33, p. 603. Var. **obtusàta,** Rehd. Of compact habit and slow growth: lvs. elliptic or oval, obtuse at both ends, 2–3 in. long. Var. **polypétala,** Nichols. (var. *monstruòsa*, Mouillef.). Fig. 2031. Corolla divided into 5 narrow petals which gives to the fls. a feathery appearance. G.F. 3:453 (adapted in Fig. 2031). Var. **rùbra,** Sweet (var. *Pavártii*, André). Fls. deep pink. R.H. 1888:540.

DD. *The lvs. mostly opposite or in 3's, obtuse.*

E. *Under side of lvs. glabrous.*

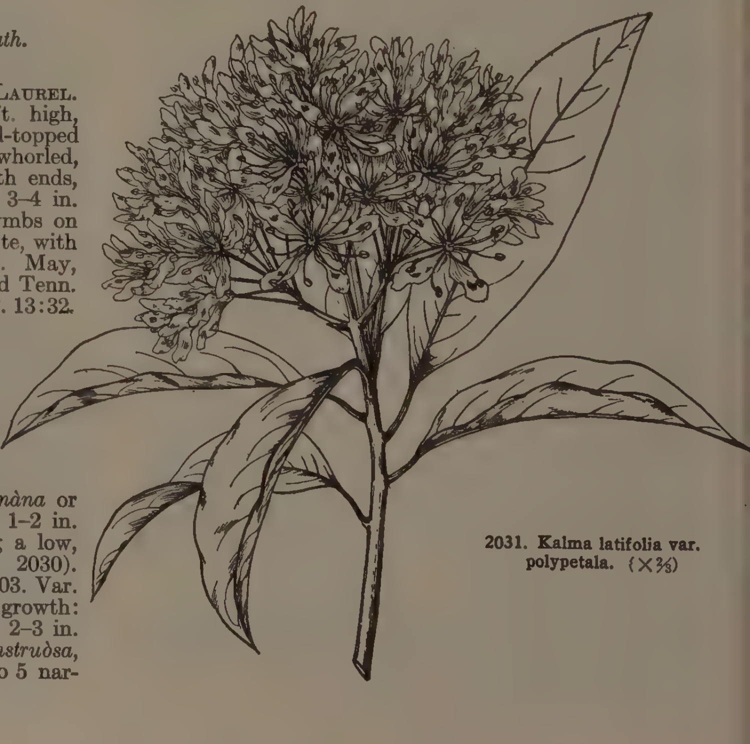
angustifòlia, Linn. SHEEP-LAUREL. LAMBKILL. WICKY. Shrub, to 3 ft.: lvs. petioled, usually oblong, obtuse, light green above, pale beneath, 1–2½ in. long: corymb lateral, many-fld., compound or simple; fls. ⅛–½in. across, purple or crimson; sepals ovate, glandular. June, July. From Newfoundland and Hudson Bay to Ga. B.M. 331. Em. 445.—There are varieties with light purple fls., var. **ròsea,** Hort.; with crimson fls., var. **rùbra,** Lodd. (var. *hirsùta*, Voss). L.B.C. 6:502; with white fls., var. **cándida,** Fern.; with ovate or oval lvs., var. **ovàta,** Pursh, and of dwarf habit, var. **pùmila,** Bosse (var. *nàna*, Hort.).

EE. *Under side of lvs. pubescent.*

carolìna, Small (*K. caroliniàna*, Day). Similar to the preceding, but the young parts finely pubescent: lvs. oval to oblong, obtuse, grayish pubescent below, ⅔–1¾ in. long: fls. purplish, ⅓in. across, in small corymbs; sepals oblong-lanceolate, puberulous. June, July. Va. to N. C. B.B. (ed. 2) 2:684.—Has proved hardy at the Arnold Arboretum.

CC. *Branchlets 2-edged: lvs. glaucous-white beneath, all opposite or in 3's.*

polifòlia, Wang. (*K. glaùca*, Ait.). Low, straggling shrub, to 2 ft.: lvs. almost sessile, oval to linear-oblong, obtuse, revolute at the margins, ½–1½ in. long: fls. in simple terminal umbels, slender-pedicelled, ½–¾in. across, rose-colored or purplish. May, June. Newfoundland to Pa. and in the Rocky Mts. from Sitka to Calif. B.M. 177. L.B.C. 16:1508. Em. 441. Var. **microphýlla,** Rehd. (*K. microphýlla*, Heller), is the alpine form of the Rocky Mts., growing only a few inches high, and with very small lvs., ½in. or less long. Var. **rosmarinifòlia,** Rehd. (*K. glaùca* var. *rosmarinifòlia*, Pursh), has narrow, linear-oblong, strongly revolute lvs.



2031. Kalma latifolia var. polypetala. (×⅗)

BB. *Lvs. deciduous, alternate.*

cuneàta, Michx. Fig. 2032. Erect shrub, with slender, straggling sts. to 3 ft.: lvs. petioled, cuneate, obovate-oblong, acute or obtuse, pubescent beneath when young, ¾–1½ in. long: fls. slender-pedicelled, in few-fld. lateral umbels, creamy white with a red band within, ½–¾in. across. June. N. C. and S. C. G.F. 8:435 (adapted in Fig. 2032). B.M. 8319.—Tender.

AA. *Fls. solitary, axillary: plant hirsute.*

hirsùta, Walt. (*Kalmiélla hirsùta,* Small). Low shrub, with many erect or ascending sts. to 1 ft.: lvs. alternate, almost sessile, oblong to lanceolate, ¼–½in. long: fls. slender-pedicelled, ½in. across, rose-purple; sepals oblong-lanceolate, hirsute, longer than the caps. June. S. Va. to Fla. B.M. 138. L.B.C. 11:1058.—Tender.

ALFRED REHDER.

KALOPÀNAX: *Acanthopanax.*

KALOSÁNTHES: *Rochea.*

KARÀTAS: *Aregelia.*

KAULFÚSSIA: *Charieis.*

KENDRÍCKIA (personal commemorative name). *Melastomàceæ.* A warmhouse root-climber from S. India and Ceylon, where the sts. "in their lower part creep up trees like ivy, hence flattened with the lvs. distichous." Species one, **K. Wálkeri,** Hook. f., offered abroad: lvs. opposite, fleshy, stalked, oblong or obovate, obtuse, about 1½ in. long, the margins glandular-hairy and the surface dotted white: fls. "tinging the forest red" when the plants ascend to the tops of the tallest trees, borne in few-fld. umbels or solitary; calyx rose-purple, urn-shaped; corolla bright red, the 4 fleshy petals about 1 in. long; stamens 8, equal, the anthers opening at the apex by a pore and somewhat produced or extended at the base: fr. a globose caps. opening by 4–6 valves at the apex. Probably requires the treatment given other warm melastomaceous plants. See *Melastoma.*

L. H. B.

KENNÉDYA (Kennedy, of the nursery firm of Kennedy & Lee, important English nurserymen of the latter part of eighteenth century). *Leguminòsæ.* Woody trailers or twiners, making excellent plants for the intermediate house or conservatory.

Perennials, usually pubescent or villous, prostrate and trailing or climbing, the st. more or less woody: lvs. mostly pinnately 3-foliolate, sometimes with 5 lfts. or even reduced to 1, the lfts. stipellate, entire or somewhat 3-lobed: fls. papilionaceous, red to almost black, disposed in pairs, umbels or racemes, or sometimes solitary; calyx 2-lipped by the cohesion of 2 upper lobes; standard orbicular or obovate, narrowed to a claw, and bearing minute auricles; wings falcate, joined to the incurved keel; stamens 9 and 1: pod linear, flattened or cylindrical, 2-valved with pithy divisions between the seeds.—Species about a dozen, in Austral. Closely allied to Hardenbergia, but differs in the larger red or red-black rather than white or blue fls., and characters of keel and infl. These genera belong to the Phaseolus tribe.

The species are known mostly as glasshouse subjects. They propagate with ease from seeds, and also from cuttings of firm green wood; they require an intermediate temperature. Insects are likely to trouble them. They are mostly spring and summer bloomers, and should rest in winter. Give plenty of water during summer. They should be given support; they grow from 3 to 10 feet high, making stiff, woody stems. They may be trimmed back freely when at rest. The taller kinds, like *K. rubicunda* and *K. coccinea,* are excellent for rafters. *K. nigricans* is an old garden plant, still grown in this country under the name of *Lotus nigricans.* Well-rooted plants may be planted permanently in the greenhouse border.

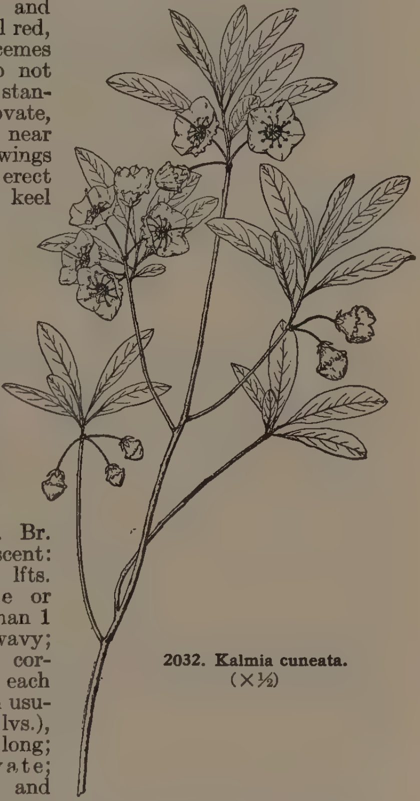
A. *Fls. nearly black.*

nígricans, Lindl. Twining, robust, somewhat pubescent: lfts. (sometimes reduced to 1) broad-ovate or rhomboid, entire, obtuse or emarginate, 2–3 in. long; stipules small and reflexed: fls. slender, 1 in. or more long, in short 1-sided axillary racemes, deep violet-purple or almost black, green-blotched on the standard which is narrowly obovate and reflexed; wings about as long as keel, and narrow: pod flattened. W. Austral. B. R. 1715. B.M. 3652.—An immense grower in S. Calif.

AA. *Fls. red or scarlet.*

B. *Standard narrow-obovate.*

rubicúnda, Vent. Pubescent, twining: lvs. 3-foliolate; lfts. 3–4 in. or more long, ovate to orbicular or ovate-lanceolate, entire; stipules small and reflexed: fls. dull red, drooping in racemes that usually do not exceed the lvs.; standard narrow-obovate, reflexed from near the middle; wings narrow and erect adhering to keel above the middle: pod flat or nearly so. L.B.C. 10:954. B.M. 268 (as *Glycine rubicunda*). B.R. 1191 (as *Amphodus ovatus*). H.F. II. 4:166.



2032. Kalmia cuneata. (×½)

BB. *Standard broad-ovate or orbicular.*

prostràta, R. Br. Prostrate, pubescent: lvs. 3-foliolate; lfts. broad-obovate or orbicular, less than 1 in. long, often wavy; stipules leafy, cordate: fls. 2–4 on each peduncle (which usually exceeds the lvs.), scarlet, ¾in. long; standard obovate; keel incurved and obtuse; wings narrow and short: pod nearly cylindrical, pubescent. B.M. 270 (as *Glycine coccinea*). J.H. III. 44:65.

Var. **màjor,** DC. (*K. Márryattæ,* Lindl. *K. Marryattiàna,* Hort.). Larger and more hairy, twining: lfts. larger, strongly undulate; stipules sometimes 1 in. across: fls. large, deep scarlet. B.R. 1790. Gn. 28:60. Gn.W. 4:505. H.U. 5, p. 139. A.F. 3:547.—A very handsome winter-flowering twiner.

coccínea, Vent. Prominently pubescent, trailing or twining: lfts. 3 or 5, ovate or oblong, very obtuse, often somewhat 3-lobed; stipules very small: fl. ½in. long, scarlet, in long-peduncled clusters of 15–20; standard orbicular; keel very obtuse, short: pod flattened. B.M. 2664. L.B.C. 12:1126.—Known under several names, as *K. inophýlla,* Lindl., B.R. 1421; *K. dilatàta,* Cunn., B.R. 1526; *Zíchya trícolor,* Lindl., B.R. 25:52; *Z. villòsa,* Lindl., B.R. 28:68, and others. Handsome slender twiner or trailer.

K. audomariénsis, Hort., is probably a form of Hardenbergia monophylla, although reputed to be a hybrid between that species and K. prostrata var. major (K. Marryatæ). Fls. rosy red, in racemes: lvs. ovate-lanceolate, acuminate, petioled: handsome. R.B. 27:25.—*K. Beckxiàna*, F. Muell. Much like K. rubicunda, but peduncles 2-fld.: twining: lvs. 3-foliolate, the lfts. obovate to elliptic, to 3 in. long: fls. red with a green-yellow dark-margined blotch at base of standard, about 1½ in. long. S.W. Austral. B.M. 8358. A showy and striking plant.—*K. cærùlea*, Hort., is probably Hardenbergia Comptoniana.—*K. Comptoniàna*, Link.=Hardenbergia Comptoniana.—*K. exímia*, Lindl. Twining or prostrate, silky or becoming glabrous: lfts. 3, ovate, or obovate, not exceeding 1 in. long, very obtuse. fls. scarlet, not large, 2 or 3 more on a peduncle; standard very broadly obovate or nearly orbicular: pod usually curved. W. Austral. P.M. 16:35. H.F. 4:166.—*K. longiracemòsa*, Lindl.=Hardenbergia monophylla.—*K. macrophýlla*, Lindl.=Hardenbergia Comptoniana.—*K. ovàta*, Sims=Hardenbergia monophylla.—*K. retrórsa*, Hemsl. Twining, reddish hairy on the young growths: lvs. 3–6 in. long, 3-foliolate, petioled; lfts. oval to sub-orbicular: fls. rose-purple with white spot on standard, about ⅗in. across, borne in a peduncled raceme: pod retrorsely pilose. E. Austral. B.M. 8144.—*K. Stírlingii*, Lindl. Hairy, trailing or twining: lvs. 3-foliolate, ovate to orbicular, very obtuse; stipules broadly cordate: fls. scarlet, in 1–3 pairs on axillary peduncles: pod very turgid. W. Austral. B.R. 1845.

L. H. B.

KÉNTIA (after William Kent, horticulturist, companion of Reinwardt in journeys through the Indian archipelago). *Palmàceæ*, tribe *Arèceæ*. Ornamental spineless palms grown in the greenhouse.

Leaves pinnate, sharp-pointed or 2-toothed; lfts. linear-lanceolate, midnerves scaly beneath, and rachis angled above; petiole channelled above, rounded on the back. It differs from Areca in the sharply 4-angled branchlets of the spadices; and from Hedyscepe and Kentiopsis in having only 6 stamens.—Species at most 6 or 7, from the Moluccas to N. Austral. The type is *K. procera*, Blume, from New Guinea, which is not cult. It is probable that none of the kentias known to the American trade belongs properly in this genus.

K. austràlis, Hort., from Lord Howe's Island, is probably one of the four following palms which, according to Maiden in Proc. Linn. Soc. N. S. W. 1898, are the only palms on that island: Clinostigma Mooreanum, Howea Belmoreana and H. Forsteriana, and Hedyscepe Canterburyana. K. australis was intro. 1873 and advertised 1893. —*K. Baùeri*, Seem.=Rhopalostylis Baueri.—*K. Belmoreàna*, C. Moore=Howea Belmoreana.—*K. Belmoreàna*, F. Muell.=Howea Belmoreana.—*K. Brównii*, Hort. Dedicated to D. S. Brown, of St. Louis, Mo. Resembles K. Macarthuri. Lvs. pinnate, arching; lfts. truncate and premorse. Very graceful. A.G. 15:266. This is, perhaps, Nenga or Hydriastele.—*K. Canterburyàna*, F. Muell.=Hedyscepe Canterburyana.—*K. divaricàta*, Planch.=Kentiopsis divaricata.—*K. Dumoniàna*, Hort. Adv. 1895. F.R. 1:379.—*K. élegans*, Brongn. & Gris.=Cyphophœnix elegans.—*K. exhorrhìza*, Wendl.=Exhorrhiza Wendlandiana.—*K. Forsteriàna*, F. Muell.=Howea Forsteriana, considered by Bentham to be only a form of Howea Belmoreana, although horticulturists do not accept this.—*K. frutéscens*, Hort. Cult. by Siebrecht & Son.—*K. fulcìta*, Brong.=Cyphophœnix fulcita.—*K. grácilis*, Hort.=Microkentia gracilis.—*K. Kersteniàna*, Hort. Lvs. very slender, dark green, arching, ascending, widely pinnated; lfts. broadly cuneate, shaped like a shark's fin, the truncate apex curiously erose, ragged, the upper margin extending into a long, sharp tip; petioles covered with light grayish brown pubescence. New Ireland. A.G. 20:223 (1899). G.C. III. 24:391. This is probably a Nenga.—*K. Líndenii*, Hort.=Kentiopsis macrocarpa.—*K. Luciàni*, Lind.=Kentiopsis macrocarpa.—*K. Macárthuri*, Hort.=Ptychosperma Macarthuri, which see.—*K. Mooreàna*, F. Muell.=Clinostigma Mooreanum.—*K. Mòrei*, Hort. Dreer. Possibly same as K. Mooreana.—*K. rubricaùlis*, Hort. Lvs. pinnate, ovate, with red petioles. Adv. 1895.—*K. rupícola*, Hort. Adv. 1895.—*K. Sanderiàna*, Hort. Very slender in habit, very hard foliage, spreading: lfts. very narrow, arranged on an arching rachis similar to Cocos Weddelliana. A graceful plant for jardinieres or conservatories. A.G. 20:223. A.F. 20:603. Gn.M. 2:226. G. W. 2:399.—*K. sápida*, Mart.=Rhopalostylis sapida.—*K. Van Hoùttei*, Hort.=Veitchia, sp. (?). Adv. 1895.—*K. Vèitchii*, Hort. probably = Hedyscepe Canterburyana.—*K. Wendlandiàna*, F. Muell.=Hydriastele Wendlandiana.

N. Taylor.†

KENTIÓPSIS (Greek: *like Kentia*). *Palmàceæ*. A small but very handsome group of palms with tall unarmed stems.

Leaves equally pinnate; pinnæ sub-opposite, very coriaceous, narrow, sword-shaped, narrowed to the obtuse or toothed apex, with strong mid-nerve, prominent veins and thickened margins: spadix large, thick, the branches stout and long; fls. monœcious, spirally disposed; ovary globose-ovoid followed by a thick-walled fr.—There are 3 species, all Australian. G.C. II. 25:75. Kentiopsis belongs to a large group of genera mentioned under Hedyscepe, which differ from Kentia in having the ovule fastened on the side of the locule, and more or less pendulous, instead of fastened at the base and erect, as in Kentia. Kentiopsis is distinguished from Hydriastele by having its fls. arranged spirally instead of in 4 ranks. From numerous other cult. allies it is distinguished by the following characters: stamens numerous, 20–25: lf.-segms. narrowed, obtuse or dentate: sepals of the staminate fls. triangular-orbicular, broadly overlapping. Cult. as in Kentia.

macrocárpa, Brongn. (*Kéntia Líndenii*, Hort., Lind. *Kéntia Luciàni*, Lind.). About 20 ft., usually less in cult.: rachis flat above, convex below. The form known as *Kéntia Luciàni*, has bright green lvs., tinged with brown on the under surface, the young petiole yellowish, later becoming brown. I.H. 24:276; 29:451. R.H. 1881:372. F. 1884, p. 71. S.H. 2:117.—The species is distinguished by the reddish tinge of the young lvs.

K. divaricàta, Brongn. (Kentia divaricata, Planch.), is referred by Drude in Engler & Prantl, to Drymophlœus. It may be distinguished from the preceding by the alternate pinnæ and triangular rachis, keeled above. I.H. 28:409. This has been confused in the trade with Kentia gracilis, which is referred by Index Kewensis to Microkentia gracilis. See I.H. 23:245. Advertised 1895.—*K. olivæfórmis*, Brongn., is characterized by the 4-angled rachis. Not cult.

N. Taylor.†

KENTUCKY BLUE GRASS: *Poa pratensis.*

KENTUCKY COFFEE TREE: *Gymnocladus canadensis.*

KERNÈRA (Johann Simon von Kerner, 1755–1830, professor of botany at Stuttgart). *Crucíferæ*. Under this name amateurs cult. a rock-plant growing about 4 in. high, which blooms profusely all summer, its fls. being small, white, and borne in elongated umbels. Bentham & Hooker regard Kernera as a subgenus of Cochlearia, in which the stamens are longer and bowed at the apex: pods turgid; valves very convex: cotyledons accumbent or incumbent. Prantl (in Engler & Prantl, Pflanzenfamilien), however, keeps the genus distinct, comprising 5 species in the mountains of Cent. and S. Eu. They are perennial herbs, with simple or pinnately parted lvs.

The species grown in rock-gardens is a compact branching, neat-habited plant thriving in any light soil that is moderately rich. It requires a sunny but not too dry situation. Prop. by cuttings, division or seed. *K. saxátilis*, Reichb. (*Cochleària saxátilis*, Linn.). Root-lvs. oblong, dentate, pilose; st.-lvs. linear-oblong: petals 4, obovate, 2–3 times as long as the calyx: seeds numerous, not margined. Pyrenees to Carpathians.

Wilhelm Miller.

KÉRRIA (after William Kerr, a gardener who introduced this and many other plants from China; d. 1814; not J. Bellenden Ker or M. Kerr, as often stated). *Rosàceæ*. A monotypic genus, one of the first shrubs brought from Japan, best known by its weak, slender green branches, slender irregularly toothed leaves and large yellow flowers.

From Rhodotypus, a close relative, it differs in its 5 rather than 4 petals, 5–8 rather than 4 carpels, and in the dry achene rather than drupe. The related genus Neviusa lacks petals, and has 2–4 carpels. **K. japónica**, DC. (*Córchorus japónicus*, Thunb.), is a very common bush in yards under the name of Japanese Rose, Corchorus and the prevailing double form as Globe-flower. (Fig. 2033): lvs. simple, alternate, ovate-lanceolate, acuminate, largely unequally serrate, 1–2 in. long, clear green above, pale below, thin, slightly pubescent: fls. abundant, solitary, terminal, peduncled, 1–2 in. diam. appearing in June and more or less throughout the year; calyx persistent, 5-lobed; petals 5, large, yellow, ovate; stamens numerous: carpels 5–8, globose, distinct. A.G. 18:425. F.E. 9:593. R.H. 1869, p. 293. Gn. 21, p. 275. Var. **flore-plèno**, double, more vigorous and more frequent in cult. than the single. B.M. 1296. G. 26:345; 27:146. G.M. 50:210. G.Z. 9:48. Var. **grandiflòra**, a vigorous form with large fls. Var.

vittato-ramòsa, Zabel (*K. ramùlis variegàtis aùreis*), a dwarf form, the branches striped with yellow and green. Var. **argénteo-variegàta,** 2–3 ft. high, with small green lvs. edged with white.

Kerria japonica grows 4 to 8 feet high and as broad as high, with numerous short-branched, spreading stems, attractive in winter from its light green branches; in early June, when its blossoms appear in greatest abundance; in November, when the leaves are of a clear yellow; and is not unattractive throughout the whole year. It is a refined plant and deserves free use in ornamental planting, either in simple masses or at the front of a shrubby group or border. It is not thoroughly hardy in all situations in the northern states, the tips of its branches often winter-killing, which causes it to demand a well-drained and partially sheltered position. It grows in any good garden soil. Although enduring sunlight, it is best in partial shade, since the intensity of full sunlight partially bleaches the flowers. It is propagated by cuttings, layers and root-divisions.

2033. Kerria japonica, the single-flowered form. (×½)

A. Phelps Wyman.

KERSTINGIÉLLA (Dr. Kersting, of Togoland). *Leguminòsæ*. A very recently described African plant that produces a bean underground, much after the manner of peanut. It is widely cult. by the natives of Trop. Afr. for food, *K. geocárpa*, Harms (*Voandzèia Poìssonii*, Chev.). It is a prostrate herb, the main st. creeping, 2–3 in. long, and rooting at the nodes: lvs. 3-foliolate, rising on slender petioles, the lfts. broadly ovate or obovate, obtuse: fls. small, in pairs or solitary, subsessile in the axils (on the ground); corolla papilionaceous, greenish white but the standard pale violet at tip: pod maturing underground, indehiscent, usually divided by 1 or 2 constrictions into 2 or 3 joints; seeds oblong or oblong-ovoid, about ¼in. long, white, red or mottled: "after fertilization, the solid base or stipe of the pistil, which in the fl. is very short, lengthens into a carpopodium and at the same time turns toward the ground; then the corolla and the style are thrown off. The ovary, still very small, is pushed out of the calyx, and by the root-like carpopodium gradually driven into the ground, where finally the growth and the maturation of the ovary into the seed-bearing pod take place."—Kew Bull., 1912, p. 209, with fig. See *Voandzeia*.

L. H. B.

KETELEÈRIA (after Jean Baptiste Keteleer, a French nurseryman, born in Belgium). *Pinàceæ*. Ornamental trees, grown for their handsome fir-like foliage and distinct habit.

Evergreen, of regular pyramidal habit while young, in old age with a broad flat-topped head: winter-buds globose or ovoid, not resinous: lvs. linear, flat or keeled, not grooved above, pale green below, appearing 2-ranked: staminate fls. arranged in clusters: cones upright, with persistent woody scales; bracts inclosed, about half as long as the scales; wings of seeds as long as the scales.—Three or possibly only 2 species in China. Closely allied to Pseudotsuga and chiefly distinguished by the clustered staminate fls. and the upright fir-like cones. In foliage most similar to Abies but easily distinguished by the flat lvs. being keeled, not grooved above and pale green, not marked with white or whitish lines beneath.

The keteleerias are little known in this country and are not hardy North, though the recently introduced *K. Davidiana* is probably hardier than the better known *K. Fortunei*. They are handsome trees, of fir-like habit while young, but old trees become flat-topped with wide-spreading branches resembling somewhat the cedar of Lebanon in habit. Propagation is by seeds and by cuttings.

Fórtunei, Carr. (*Àbies Fórtunei*, Murr. *Pseudotsùga jezoénsis*, Bertrand. *Pìnus Fórtunei*, Parl. *Abiètia Fórtunei*, Kent). Tall tree, to 100 ft.: branchlets glabrous, orange-red: lvs. twisted so as to form 1 plane, linear, rigid, mucronate or spiny-pointed, flat, with the midrib prominent on both sides, glossy dark green above, paler below, 1–1¼ in. long: cones ovoid or cylindric-ovoid, 3–7 in. long; scales suborbicular, purple while young, later reddish brown. S. E. China. R.H. 1866:449; 1887, pp. 208–211; 1900, p. 202; 1904, p. 130. G.C. II. 21:348, 349. F.S. 7, p. 223; 9:858. J.F. 4, p. 29. G.W. 3, p. 125.

Davidiàna, Beissn. (*Àbies Davidiàna*, Franch. *Pseudotsùga Davidiàna*, Bertrand. *Àbies sàcra*, David). Tall tree, to 120 ft.: young branchlets puberulous: lvs. twisted into 1 plane, linear rounded or notched at the apex, midrib raised on both sides, glossy green above, paler below, 1–1½ in. long: cones cylindric-oblong, 6–8 in. long, with orbicular-ovate scales, erose at the margin and recurved at the apex. W. China. R.H. 1873, pp. 37, 38; 1904, p. 131. G.C. III. 33:85. M.D.G. 1912:9 (habit of an old tree).

K. Evelyniàna, Mast. Closely allied to K. Davidiana and probably only variety of it. Lvs. 1½–2 in. long, obtuse or acutish: cones 2–3 in. long, with oblong-ovate scales. S. W. China. G.C. III. 33: 194.—*K. Fàbri*, Mast.=Abies Delavayi, Franch., a recently intro. Chinese species.

Alfred Rehder.

KIDNEY BEAN. Common name in England for the garden beans in distinction from the lima bean, the former being *Phaseolus vulgaris*, the latter *P. lunatus*.

KIDNEY VETCH; *Anthyllis*.

KIGÈLIA (from a native name). *Bignoniàceæ*. About a dozen trees of Trop. Afr. (one extending into S. Afr.), remarkable for the long-hanging fls. and frs. Lvs. odd-pinnate: fls. orange or red, on long-peduncled lax panicles; calyx 2–5-lobed, campanulate; corolla broadly campanulate and narrowing below into a straight cylindrical or constricted tube, the limb 2-lipped; upper lip 2-lobed and nearly erect; lower lip deeply 3-lobed and deflexed; stamens 4, didynamous, somewhat or partially exserted; disk ring-like: fr. a cylindrical, indehiscent rough body, with a thick exterior and a fibrous pulp holding the seeds. **K. pinnàta,** DC. (Fig. 2034), the "fetish-tree" and "sausage-tree," is offered in S. Calif., and specimens may be expected in botanical collections in the W. Indies. It is native of the Mozambique district in Afr., where it makes a tree 20–50 ft. high, according to Sprague: lvs. ternate, the lfts. 7–9, elliptic-oblong or obovate and 3–6 in. long, serrate or entire, usually glabrous above but sometimes more or less pubescent beneath, the lateral lfts. sessile but the terminal one with a stalk several inches or a foot long: fls. claret-colored, with a corolla-tube to 3 in. long dilated at the mouth, and lobes to 2½ in. long: fr. 12–18 in. long, blunt, 5 in. diam., hanging on a peduncle or cord often several ft. long, making very striking objects. In parts of Afr. this tree, or possibly a related species, is said to be held sacred; and the fr., when cut and slightly roasted, is said to be used as outward applications in certain diseases. The tree is practically unknown in the U. S. G.C. III. 50, suppl. Aug. 12 (1911).

L. H. B.

KIN-KAN: *Kumquat.*

KINNIKINNICK: Dry bark of *Cornus Amomum*, smoked by western Indians.

KINO. A dark red or blackish plant product, usually of a resinous nature, rich in tannin. There are numerous kinds of kino obtained from plants of different families; some are used in medicine as an astringent, others are employed in dyeing and tanning. The Australian or Botany Bay kino is derived from various species of Eucalyptus. *E. resinifera* is known as the kino eucalypt.

KIRENGESHÒMA (Japanese words meaning *yellow Anemonopsis macrophylla*). *Saxifragàceæ.* One perennial yellow-flowered herb from Japan, *K. palmàta*, Yatabe, which has lately received attention in England where it has proved hardy and appears to be adapted to the shady border or rock-garden; prop. by division. The plant grows at an elevation of over 5,000 ft. in Japan, on Mt. Ishizuchi. Two to 4 ft., upright, the sts. slender and glabrous: lvs. large and papery, all the lower ones petioled, round-cordate and palmately 7–10-lobed, hairy on both surfaces, the lobes acute and coarsely toothed: fls. overtopping the lvs., on usually 3-fld. peduncles, nodding; corolla bell-shaped, to 1¾ in. long, the 5 petals oblong-lanceolate and recurved above the middle: fr. a loculicidally dehiscing caps. B.M. 7944. Gn. 64, p. 246; 74, p. 573. G. 27:421. R.H. 1908, p. 153.

L. H. B.

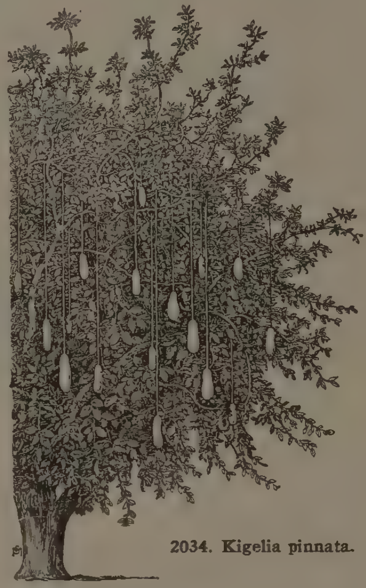
KITAIBÈLIA (Paul Kitaibel, 1757–1817, of the botanic gardens at Pesth). *Malvàceæ.* One garden species from the S. Danube region, planted in the open, **K. vitifòlia,** Willd. Hardy robust perennial herb, to 8 ft., allied to Malope: lvs. angled or 5-lobed, toothed: fls. white or rose, showy, sometimes many and sometimes solitary in the axils; involucre surpassing the calyx, the bracts connate at base and 6–9-parted; calyx 5-parted; petals 5, obovate, narrowed almost to a claw; staminal column divided at apex into many filaments; ovary many-celled, the carpels becoming congested into a head, dehiscent. It is a plant somewhat on the order of abutilon, with vine-like or maple-like lvs. It thrives in any usual garden soil, and is said to be good for naturalizing in the shrub plantations and elsewhere; prop. by division or by seeds. B.M. 821.

K. Balánsæ, Boiss., is a second species very like K. vitifolia, but the lvs. deeply 5-lobed, stipules ovate, the bracts of involucre much exceeding calyx and oblong-lanceolate and cohering or grown together at base. Cilicia.—*K. Líndemuthii*, Hort., is a graft-hybrid, produced by grafting K. vitifolia on Abutilon Thompsonii. Lvs. variegated or marbled as in the abutilon stock: plant 6–8 ft. Named for H. Lindemuth, of Berlin, its raiser.

L. H. B.

KITCHEN - GARDEN and FLOWER - GARDEN. The kitchen-garden is for the kitchen,—to grow the supplies that are used in cookery and on the table as food. We ordinarily think of it only as a vegetable-garden, yet it may grow strawberries and other small fruits; and in England the melons are classed with fruits even if grown in the kitchen-garden. It is in the kitchen-garden, also, that the sweet herbs and the garnishing plants may be grown; and flowers need be no strangers to it. In fact, some of the best and most attractive kitchen-gardens may be comprised of vegetables, fruit bushes and flowers,—all grown for the table and the home.

The essential idea is the home-gardening idea; and therefore it is difficult to separate the home vegetable-garden and the home flower-garden by any hard-and-fast or arbitrary line.



2034. Kigelia pinnata.

If the place is large enough to have been laid out in a landscape treatment, the home-garden area has been set aside in its place, proper both for exposure and convenience. With this landscape plan we have nothing to do at the moment except to insist that the home-garden idea shall not have been overlooked and that it shall form one essential part in an artistic subdivision of the property.

The kitchen-garden of vegetables.

Human diet consists chiefly of three classes of foods. first, meats, high in protein, useful for structural purposes; second, cereals and other starchy or carbohydrate foods, useful for their high fuel-value; and third, vegetables and fruits. The last mentioned contain but little material for building body or for supplying energy; but they offer other substances seemingly less important, but which are absolutely essential. Most notable among these are the mineral elements. The flavoring and appetizing qualities are scarcely less important, and the requirement for comparatively bulky foods is no more to be neglected in human than in animal nutrition. The truth of these assertions is evident in the fact that no meal is regarded as complete without its vegetarian dishes, and more especially is it emphasized in the intense craving for this sort of food which is experienced in the spring months by those who enjoy but little of it during the winter. Indeed, one can hardly avoid tracing a connection between the meat and cereal diet of the old-time winter and the once accepted notion that one must necessarily be in poor physical condition as spring approaches, and resort to the use of "spring bitters." In fact, certain definite disorders are clearly traced to the lack of vegetable food.

More appealing than the nutritional value of the vegetable food is its value as a contribution to good living. No diner is satisfied unless vegetables appear on the menu, and the products of the garden add widest variety in the form of condiment and salad, as well as in the main part of the meal. Paragraph after paragraph might be written in praise of the endless array of delicacies which are offered by the skilful housewife who is in league with the skilful gardener.

Vegetable food is procured in two ways,—by purchase and by culture. The former method is not available to many who dwell in the open country. To the townsmen it is open to very serious objection. The cost is usually high, often exorbitant and prohibitive. The varieties are more often selected for resistance to the rigors of shipment and sale than for excellence of table quality. For example, the leading commercial sort of celery is far surpassed by others, and the most widely grown winter cabbage—the best keeper of all—lacks tenderness and flavor. The market watermelon of long experience in freight cars sadly lacks in quality. Even though a product be good when it leaves the farm, the delays in handling to which it is subjected rob it of its freshness and its delicacy of flavor. Lettuce cannot be made to retain its garden crispness, and the sweetness of sugar corn speedily departs. Moreover, market-bought vegetables are often in thoroughly unclean condition.

The second source of supply is the kitchen-garden. By this means are the shortcomings of the urban vegetable supply avoided by many townsmen, and a notable contribution to the farm income is afforded. An experiment continued for five years at the Illinois Experiment Station showed an average return of $105 from a half-acre garden. The average cost was $30. Under intensive culture on small areas, each square foot of ground may be brought to yield, for example, lettuce to the value of 10 or 12 cents, followed by tomatoes worth 6 to 12 cents. These figures are offered merely to suggest possibilities and not to form a basis for calculating the value of back-yard gold mines. Perhaps the gold mine is there, but many factors must be considered in figuring its profits. It is safe to say that in the hands of a skilful gardener a city back yard may mean as much to the family budget as a 5 per cent increase in an ordinary "middle class" salary, and a suburban garden offers far greater possibilities. In the dooryards and vacant lots of our cities lie locked up one of the great economic resources of the state. The value of products of the kitchen-gardens in New York alone already runs into the millions of dollars and should be many times doubled. So much for the material gain. No less to be prized are the dividends which are paid in the joys of a variously laden table and in the satisfaction and pleasure of production. The city dweller can find no better means of recreation and exercise. A garden is an ideal hobby.

It is impossible to tell in detail how to make a garden. It is possible only to offer certain generalities and suggestions which may be helpful to one who is learning how to cope with a given set of conditions. Circumstances vary so widely that almost any statement may be wrong in some cases, and rule-making is always unsafe. Experience is the best teacher, and one who loves plants and the soil and who is willing to see and to think and to do the best that one knows may be confident of increasing success from year to year.

Location.

It often happens that no choice is offered as to the location of the vegetable-garden, but when this is not the case, an outline of desirable points may be of service. While one whose domain is measured in feet and inches rather than in rods is forced to utilize the plot which is at hand, the garden factor should certainly be considered in choosing a place for a home.

On the farm the garden should be near the buildings, for convenience in working. The distant garden is almost invariably neglected, while the nearby plot offers useful employment for odds and ends of the time of farm-hands which might otherwise be wasted. For example, the cultivation of a corn-field is finished an hour before noon. It is too late to go to a distant field, and the horse is turned into the home half-acre not to browse but to loosen the crusted soil. The garden should be near the home for convenience in gathering the products. If possible, a liberal water-supply should be available.

A gentle slope is desirable to insure good drainage. Exposure to the southeast affords the maximum advantage from the sun's rays and consequent maximum earliness of maturity. Protection from severe winds may be gained by placing the garden near farm buildings, wood-lot or hill. At the same time, the roots of trees, greedy for moisture, should be avoided.

Three points are to be borne in mind in the choice of soil. The most important is its physical character, for this is least readily modified. Heavy clay soils are plastic, sticky, and unworkable when wet and are lumpy when dry. They are retentive though not readily receptive of moisture and of plant-food. They are cold and late in the spring. Very light sandy soils are loose and friable and are workable even when wet. They are readily receptive though not retentive of water and nutrients, and are warm and early. The ideal is a well-drained sandy loam of moderate fineness.

The second point is that plant-food should be abundant and available. Dark, loose, friable soils are usually, though not always, as in the prairie states, of relatively high fertility, while light-colored soils usually lack humus and will require heavy additions of various amendments.

Thirdly, soil that is free of weed-seeds and of disease is to be preferred, and land that has been well cultivated is more likely to offer favorable bacterial relations.

Soil management.

A good garden cannot be expected on badly drained soil. Artificial drainage is often of great advantage even on soils that are not swampy. It makes for better physical character and earlier crops. If no outlet is available, a pit filled with stone or old brick may be used.

City lots frequently offer soils that are very unfavorable for gardening operations. It is seldom that the case is hopeless, even though excavated material, brickbats and tin-cans abound. In some cases it is profitable to haul in good soil bodily, although this material is expensive. Coarse soil should be removed, and improvement brought about, if the soil is heavy, by the use of such materials as ashes, sand, other soil, manure, and lime. A stiff clay which is being broken in for garden purposes should be spaded or plowed in the fall and left in clods, in order that the frost of winter may have its full effect in rendering it workable. A sterile sand may be rendered productive by the liberal use of manure and by applications of lime.

In any garden, the main reliance for maintenance of soil fertility should be on stable manure. In this material are added nitrogen, phosphorus, and potash, the only chemical elements which are often lacking, together with large quantities of humus. Manure that has rotted for some months is better than new manure, especially if it is to be worked into the soil in the spring. However, a heavy coat of fresh material may be plowed under or spaded under each fall. It will be fairly well decayed and ready to aid the plants by spring.

In Europe, the process of trenching is frequently practised in intensive gardening. The plot is divided lengthwise, and a trench 2 or 3 feet wide and 1 to 2½ feet deep is dug across the end of one of these parts, throwing the soil outside the area to be trenched. In the bottom of this ditch is placed a heavy layer of fresh manure. The soil from the next adjoining block in the same division is turned over upon this, and a layer of manure placed in the bottom of the new ditch. Thus the work progresses to the other end of the division. Here the soil from the adjacent block of the second division is thrown into the last ditch of the first division, and then the work proceeds as before to the starting-point. The last trench is filled with the soil from the first. One or two years later the process is repeated. The layer of manure at the bottom is now well rotted and is thoroughly incorporated with the soil as the work progresses. The soil may be gradually deepened from year to year. This is a very desirable method of soil preparation, when the necessary hand labor is available.

Lime at the rate of perhaps a ton to the acre should be added every two to four years. It is useful in making clay soils more friable and in binding together very sandy soils, in correcting acidity, in freeing plant-food, and in rendering conditions unfavorable for certain diseases, although it is favorable to others. It makes little difference which form of lime is used, although quicklime is not conveniently handled. Either ground limestone rock or hydrated lime may be applied. About one-third more of the latter must be used than of the former.

The term tillage is often applied to the working of land previous to the planting of crops, and the working of soil after planting is spoken of as cultivation, although tillage properly includes all these operations. Tillage, as used to denote preparation of the land, improves the physical condition of the soil, rendering it more granular; it is useful for the improvement of the moisture relation as regards reception, retention, and transmission of moisture, it makes aëration possible, it assists in the incorporation and freeing of plant-food and in the destruction of weeds. If a soil is shallow, it should not be worked too deeply at first, but each year a bit of the subsoil may be incorporated in the surface soil, thus gradually deepening the root pasturage. The utmost care is necessary to avoid handling soils, especially the heavier sorts, when they are wet. The clayey types may be spaded or plowed with good results only at a certain stage of dryness. Experience only can teach this stage for a given soil. The work should be performed when the lumps crumble readily, as they are turned over. They should be neither plastic nor hard-baked.

When the ground is plowed or spaded in autumn, it should, as suggested above, be left rough over winter. In the spring it may be gone over with the disc-harrow or with the hoe. If plowed in the spring, the lumps should be worked down with plank drag, harrow, or rake, according to the circumstances, and a loose soil-mulch should be maintained until planting-time. If this is neglected, moisture may be lost so rapidly as to waste the equivalent of a half inch of rain a week. In very small areas, where these horse tools cannot be used, the hand implements that accomplish the same results on the soil may be employed.

For very early plantings it is well to prepare a few raised beds or ridges in autumn. These should have a southern or southeastern exposure. They will thaw out, drain and become warm much earlier in the spring than soil at the ordinary level, although they will dry out more rapidly in midsummer.

Planning.

The first task in each year's garden operations is the preparation of a good plan. This first phase of the garden work is often neglected. It should receive careful attention long before the season opens, in order that space and effort may be economized and that seed, fertilizer and other supplies may be provided. The materials for the work consist of a few good garden books and bulletins, a few catalogues of reliable seedsmen, together with paper, pencil, and ruler. A fund of experience in home-gardening is an asset of incalculable value. The aim should be to produce an abundance of vegetables of high quality, in wide variety, and as evenly distributed as possible throughout the year with a minimum of unprofitable labor and expense.

The first step is to decide what is wanted. Make a list of crops, bearing in mind the likes and dislikes of the family, even distribution through the season, adaptation to climate and soil, and the space available. List too few rather than too many, especially if the garden is small.

Avoid an over-large garden. An area 40 by 50 feet, well kept, will give greater satisfaction than a half acre neglected through press of other work. A half acre will yield a full summer and autumn supply for a large family, together with ample quantities for canning and storage. The beginner should avoid allowing his enthusiasm to lead him into deeper water than that in which he can swim. Better begin simply and let experience teach the best lines of development than to suffer failure and discouragement on account of an over-complex plan.

No area is too small to be utilized. A plot 2 feet wide and 12 feet long will yield, if well tended, as many as twenty bunches of radishes, thirty heads of early lettuce, and forty to sixty pounds of tomatoes. A fall crop of lettuce and radishes may even be matured in addition.

The larger garden should be longer than wide, in order to make the care easier. A ratio of two to one is frequently used. The rows of most crops should be far enough apart for horse cultivation. In a garden of limited area, where small amounts of many vegetables are sought, crosswise rows may be desirable. In such plots rows may be closer together, dependence being placed upon the wheel-hoe and hand-hoe for cultivation. Permanent crops, as asparagus and rhubarb, should be placed at one side to avoid interference with tillage. The hotbeds and coldframes should be in this same part of the garden. Early crops should be kept together, in order that a considerable area may be cleared up at once for later plantings. The same plants should not appear in the same part of the garden year after year. Good taste will suggest a neat arrangement, and some attention should be paid to symmetry and balance of appearance.

Three good garden plans are shown herewith, in Figs. 2035, 2036, 2037. They are by Albert E. Wilkinson, Cornell Reading-Course Bulletins. They are intensive plans,—made to utilize the land to the utmost and assuming good care, liberal fertilizing, and other close attention. With larger areas and horse labor, the distances may be greater.

The seed.

With the general plan completed, the next step is the choice of varieties and the preparation of the seed order. Only experience will offer a satisfactory knowledge of the sorts to be planted under a particular set of conditions. In the meantime, it is well to consult neighboring gardeners on this as well as on many other matters. Seed orders should be placed early to avoid disappointment as to varieties and to allow time for testing. The well-known seed firms are striving to supply good seeds, clean, viable, and true to type. Packet seeds found in grocery stores are sometimes uncertain. Many local seed-houses are thoroughly reliable.

The only true test for seed is to grow a crop from it. However, seed that will not establish in the soil a strong, healthy plant will certainly not grow a crop. It is accordingly well to test seed before it is planted. For this purpose, twenty-five, fifty, or one hundred seeds should be counted out and planted in a little box of garden soil in the house. This should be kept moist and at ordinary room temperature. Other methods of testing, by means of blotters, layers of cloth, porous dishes, and the like, afford knowledge only of the ability of the seed to sprout, not of its ability to complete the process of germination, that is, to establish itself in the soil so that it may make progress independently of the supply of food material that was stored within the seed coats.

No phase of gardening affords a more fascinating hobby than the selection and saving of seed from one's own plants. Some individuals are always superior to others, and this superiority is inherited to a greater or less degree. In the course of a series of years, remarkable progress may be made in increasing the returns from a given area. The first necessity is to establish in the mind a clear notion of the ideals to be secured. This must be very carefully worked out, for if it is necessary to modify it from year to year no progress will be made. Selections should be made on the basis of individual plants rather than of individual fruits. Every home-garden should be to some degree a plant-breeder.

Planting.

Each vegetable has its own peculiarities as to time and manner of planting. These characteristics are considered under each of the various crops.

The essentials for germination are moisture, warmth, and aëration. Light is not necessary, although, of course, it is required immediately after seedlings break ground. No general rules may be laid down for the sowing of seed. It is necessary that the soil be in good physical condition if the best results are to be attained, especially for the smaller and more delicate seeds. Seed must be sown more thickly in the case of the smaller and more delicate seeds, as celery and lettuce, in case the percentage of germination is not high, when the planting is made in very early spring, when soil conditions are unfavorable, as in a heavy soil or in time of drought, and in case serious devastation by insects or diseases is feared.

Commercial men try to know their soil and their seed and to sow just right. Until one has gained considerable experience, it is better in the home-garden to sow rather thickly, and thin after the plants have come up. Extreme thickness of sowing results in weak seedlings and a very large amount of tedious work to be done afterward.

Rules as to depth of sowing may have slight virtue, but they may also be rather seriously misleading. Seed should be sown more deeply in dry or sandy soils than in wet or heavy soils. Soaking seed before sowing is not ordinarily of very great value, although it is practised by some gardeners.

Seeds do not germinate until moisture has been imparted to them by the soil. The movement of moisture from soil to seed is a capillary movement and is more complete when there is very close contact between soil and seed. Accordingly, the soil should be carefully firmed in covering. This can hardly be overdone in

2035. Intensive plan for a fertile space 25 x 35 feet (Wilkinson) sandy soils or in those that are rather dry. Clay soils should not be packed so hard. Sowing in drills is usually regarded as better than broad-casting, because it is easier to sow the seed at uniform depth, the seedlings are of mutual assistance to one another in breaking ground, it is easier to thin and to do other work, and the plants can be more easily cultivated.

In the small garden most sowing is by hand. Many methods are practised. When the fingers are used, the seed should be worked out by means of the thumb over the second joint of the first finger. Many gardeners like to use an envelope which has been sealed at the side and cut off squarely at the end. A small quantity of seed is placed in this envelope, which is held the flat way, the opening only very slightly spread. It is held with the opening parallel to the rows and is shaken with a motion in the same direction.

Mechanical drills are now widely used and are almost indispensable in the larger gardens, the chief advantages being uniformity of work and rapidity of action. A seed-drill is not a cure-all for planting troubles. It requires as much skill as any other method. Since there is such great variation in the size of seed of a given kind, the scales on the machines can be used only as a general guide, and the machine should be tried on the bare road or on a floor before beginning work.

2036. Close-planting plan for a space 110 x 200 feet. (Wilkinson)

Growing early plants.

One of the most dearly cherished ambitions of the amateur gardener is to begin the harvest of his products very early in the season. To accomplish this, it is necessary to sow seed long before outdoor planting is possible. Plants for setting outdoors should possess such vigor and hardiness that they will make steady growth in spite of possible unfavorable conditions which they may encounter. Other advantages of starting plants in the seed-bed, either indoors or outdoors, are fuller utilization of space in the garden, greater ease in caring for both the soil of the garden and the plants themselves, better root-systems, and in some cases even greater yield. The specific methods of plant-growing are considered under the various vegetables in this Cyclopedia.

There are three ways in which this work for earliness may be managed. Seed may be sown for outdoor transplanting in small plant-boxes in the house. If plenty of window room is available and temperature within the house is under fair control, seed may be started very early and the seedlings transplanted once before they go to the garden. Another possibility is sowing seed indoors, transplanting the seedlings to the coldframe, where they are under protection for some weeks, and then placing in the garden. The next step would be the use of hotbeds and greenhouses (see *Hotbed*). The gradation in construction from hotbed to greenhouse is very simple, some houses being constructed with two rows of hotbed sash for a roof and using manure for heat. Other types may be built in all degrees of complexity. Fig. 2037 (p. 1747) shows how completely a hotbed space may be utilized.

In plant-growing, relatively low temperatures, free ventilation, sparse watering and abundant sunshine make for stockiness, hardiness, good root-systems, vigor and freedom from disease. Plants should be carefully hardened before they are placed outdoors by increasing the ventilation, lowering the temperature, and keeping them relatively dry.

Transplanting.

Soil should be in excellent physical condition if plants are to be set in it. A good degree of moisture should be present, and if possible, the work should be performed in cloudy weather or in the evening, in order that the plants may have opportunity to recover before being exposed to strong sunshine. It is not wise to undertake setting warm-blooded plants like the tomato exceedingly early, as they may be severely stunted by cold weather, even though there be no frost. Some gardeners, however, like to set out a few plants very early, expecting to replace them if necessary.

Most plants ought to be moved with a good-sized ball of earth. If the soil is in proper state of moisture and is compacted firmly about this earth ball, the plants will hardly be disturbed. Plants should ordinarily be set just a little deeper than they stood in their previous place.

Cultivation.

By cultivation is here meant the maintenance of a loose mulch of dry soil on the entire surface of the garden throughout as much as possible of the growing season. The maintenance of this mulch is of great value in retaining moisture, in keeping the soil in good physical condition, and in destroying weeds. In the small gardens, the hand-hoe and hand-weeder will meet every requirement without undue labor. A man-power wheel-hoe is useful in medium-sized gardens, usually when the rows are 40 feet or more long. The farm garden should be cultivated as far as possible by means of the horse-cultivator. When wheel-hoe and horse-cultivator are used, it is necessary to go through afterward and loosen the earth and destroy the weeds in the rows themselves. There are many types of weeders, hoes, and cultivators. Selection must be made according to the character of the soil, of the crops, and the individual fancy of the gardener himself.

Mulching.

The general effects of cultivation may be attained, in the case of thoroughly well-prepared soils, by mulching. A coat of comparatively coarse manure is spread on the soil between rows of vegetables. This practice has proved very satisfactory with celery and tomatoes. It is especially desirable with the latter crop, because it keeps down the weeds and conserves the moisture after cultivation is no longer possible.

Watering.

Hardly a summer passes in which the garden does not suffer from lack of water, in some month or other, in spite of the utmost care in cultivation. Water may be applied to small gardens by means of hose or by allowing it to flow into the furrows between the rows. Hose irrigation is usually superficial. Gardeners often think that they have watered the garden when they have merely moistened the surface. It is better to water thoroughly and less frequently than to water lightly every day. Of recent years, overhead sprinkler systems of irrigation have been devised. Those that are equipped with whirling sprays are not thoroughly satisfactory because they do not water evenly. Another type consists of pipes supported over the garden in which are inserted tiny nozzles at distances of about 3 feet. With forty pounds pressure, these nozzles will throw water for about 25 feet. The pipe is supported in such a way that it may be turned to throw a spray far to the side or directly overhead. Thus a belt 50 feet wide will be covered by a single line. The question is raised as to whether this type of irrigation would be as successful in home gardens with their many crops as it is in large commercial plantings of single crops. There seems to be little definite knowledge at present on this point, but the plan would seem to be thoroughly feasible. Nature does not water one crop at a time. Practice in the handling of garden irrigation has not been studied as fully as it should be. See *Irrigation*, p. 1682.

In warm summer weather, it is usually best to water in the evening so that the foliage will be well dried off by morning. It is not likely that watering in midday in the summer does as much harm as is ordinarily supposed.

Other work.

The summer work of training, pruning, blanching, pest control, and the like, is considered under the different entries in the Cyclopedia and under *Diseases and Insects* in Vol. II.

The last task of autumn is one of the most important,—cleaning up the garden completely. Many of the diseases and insects are wintered over in the refuse that is left on the soil.

The garden-lover who is interested in making the greatest possible progress from year to year will keep careful record of his operations. He will preserve the plan that he has drawn up for each season's operations, and, while avoiding an elaborate or cumbersome scheme, he will jot frequent notes as to dates of frost and other weather conditions, dates of planting, transplanting, and maturity of crops, behavior of plants from seed from different sources, and countless other points that will occur to him. Such a record requires but little time and is of almost incalculable advantage in future operations.

Books and bulletins.

There are many good bulletins and books on vegetable-gardening, some of them specially adaptable to the needs of the home gardener. The reader should consult the list on page 1553. The following are useful for the beginner:

"Home Vegetable Gardening," by F. F. Rockwell.
"The Home Garden," by Eben E. Rexford.
"The Vegetable Garden," by Ida D. Bennett.
"How to Make a Vegetable Garden," by Edith Loring Fullerton.
"Book of Vegetables," by Allen French.
"Manual of Gardening," by L. H. Bailey.
"The Home Vegetable Garden," Farmers' Bulletin No. 255.
"Hotbeds and Coldframes," Cornell Reading-Course Bulletin No. 30.
"Home-Garden Planning," Cornell Reading-Course Bulletin No. 34.
"Planting the Home Vegetable Garden," Cornell Reading-Course Bulletin No. 58.
"Summer Work in the Home Garden," Cornell Reading-Course Bulletin No. 92; and others.
"The Home Vegetable Garden," Illinois Circular No. 154.
"The Farmer's Vegetable Garden," Illinois Bulletin No. 105.
"Farmers' Home Garden," West Virginia Bulletin No. 122.

Tables and lists.

The home-gardener will soon acquire sufficient experience to be independent of rules and lists; and yet even the oldest gardeners like to have such lists and tables at hand to refresh the memory. The beginner is likely to follow these tables and lists slavishly and without imagination; but if he uses them as suggestions to be modified and applied in his own work, he should find them much worth the while. The remainder of this article comprises tabular material from Albert E. Wilkinson, Cornell Reading-Course Bulletin No. 34. The suggestions are for the state of New York; the consultant should know how to apply them elsewhere.

PLANTING-PLAN FOR A VEGETABLE-GARDEN 25 x 35 FEET. (See Fig. 2035.)—Wilkinson

Time for planting seeds or transplanting plants in the garden (Wilkinson).

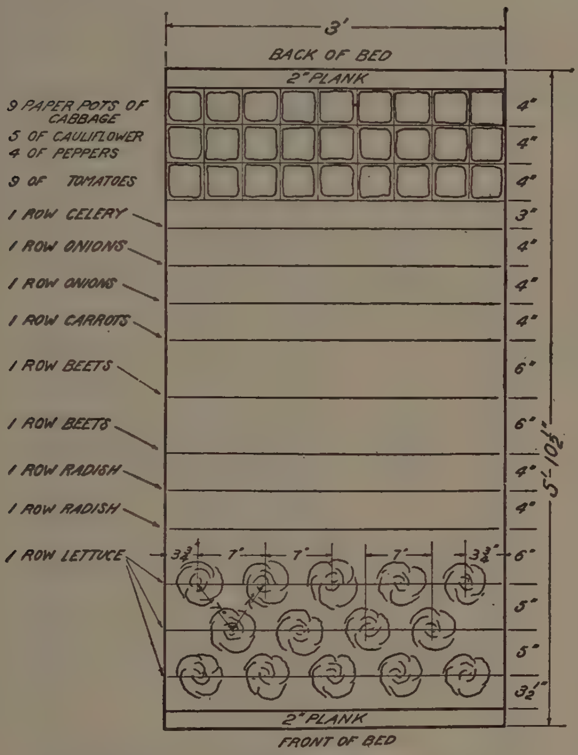
April 1–15.—Early peas (seeds).

April 15 (all seeds).—Early beets, Swiss chard, early carrots, midseason peas, radishes, parsnips, salsify, early turnips.

April 15–30 (all plants).—Early brussels sprouts, early cabbage, early kohlrabi.

May 1–10.—Early corn (seeds), lettuce (plants), endive (seeds), radishes (seeds), early celery (plants), leek (plants), onions (plants).

May 10–20 (all seeds).—Beans, green and wax; late carrots, cucumbers, late peas, early squash.



2037. Plan for the utilizing of hotbed space. (Wilkinson)

May 20–30.—Beans, shell (seeds); late beets (seeds), late squash (seeds), late turnips (seeds), cauliflower (plants), red cabbage (plants), tomatoes (plants).

June 1–10 (all seeds).—Midseason corn, lettuce, winter radishes.

June 10–20.—Late corn (seeds), late celery (plants), lettuce (seeds).

June 30.—Late cabbage (plants), late cauliflower (plants), late brussels sprouts (plants), late kohlrabi (plants), lettuce, and radishes in vacant places (seeds).

The yearly supply of vegetables (Wilkinson).

The family should plan to have for consumption, on the dates named, the following vegetables:

March 15–20 (from hotbeds).—Radishes, lettuce (leaves).

March 20–30 (from hotbeds).—Radishes, lettuce (leaves), spinach.

April 1–15 (from hotbeds).—Radishes, lettuce (head), spinach, beet greens.

April 15–30 (from hotbeds).—Radishes, lettuce, spinach, beets (small), cress, endive, parsley.

May 1–15 (from hotbeds and coldframes, and from the garden).—Radishes, lettuce (head), spinach, beets, carrots, cress, endive, parsley, rhubarb.

May 15–30 (from hotbeds and coldframes, and from the garden).—Radishes, lettuce, spinach, beets, carrots, cress, endive, parsley, rhubarb, asparagus, cauliflower, turnips.

June 1–15 (from hotbeds and coldframes, and from the garden).—Radishes, lettuce, spinach, beets, carrots, cabbage, parsley, rhubarb, asparagus, cauliflower, turnips, beans, celery, leek, onions, peas.

June 15–30 (from the garden).—The vegetables named above; Swiss chard, potatoes, squash (crookneck and white), tomatoes.

July 1–15 (from the garden).—The vegetables named above; beans (wax and green), cabbage, carrots (half-long), midseason peas.

July 15–30.—The new vegetables ready between these dates are: Carrots (long), early sweet corn (outside-grown), kohlrabi, okra.

August 1–15.—The new vegetables ready between these dates are: Beans (shell), brussels sprouts, red cabbage, savoy cabbage, cauliflower (from outside), midseason sweet corn, late peas.

August 15–30.—The new vegetables ready between these dates are: Late cabbage, cucumbers (outside-grown), muskmelons, peppers, late potatoes.

September 1–15.—The new vegetables ready between these dates are: Bur, or globe, artichokes, late corn, eggplant, parsnips, winter radishes, salsify, late squash.

September 15–30.—The new vegetables ready between these dates are: Jerusalem artichokes, late beets, late celery, celeriac, turnips.

October 1–15.—Pumpkins.

October 15–30.—Herbs harvested.

The following should be supplied for storage and winter consumption: Jerusalem artichokes, beets, carrots, celery, cabbage, celeriac, potatoes, pumpkins, parsnips, winter radishes, horse-radish, salsify, squash, turnips, onions.

Paul Work.

The home flower-garden.

The flower-garden differentiates itself from the formal plantings which comprise the main landscape gardening features. The landscape design is for general effect; the flower-garden a more intimate, homely affair, the outgrowth of a real love of flowers and their associations.

Usually it will lie within the province of the housewife to plant and cultivate the flower-garden and, for this reason, its location is of first importance. It should be convenient of access, secluded in a measure, that one may work in odd moments and odd habiliments, if convenient, and should be considered from the standpoint of convenience and personal preference. Nothing should be planted merely for show or ornament, although nothing need be left out because it is ornamental, but the flowers which most appeal to one, either from certain qualities they possess or from sentiment or association, should be much in evidence.

The platting of the garden should be on a practical working basis, with ample beds of straight outlines, with broad well-constructed paths that do not end in cul-de-sacs but afford ample room at their angles for the turning of a hand barrow or cart, for paths are not intended merely to separate the parts of the garden or to facilitate strolling in the cool of the evening, but they serve the very utilitarian purpose of a working basis for the beds. Gravel, cinders or earth paths which have been treated with a good herbicide, are preferable; if they are properly treated they will practically take care of themselves from season to season.

While the form of the plat and individual preference will usually determine the outlines of the garden, no form is more satisfactory and ample than that of beds

Planting-list of Annuals.—(A. C. Hottes, New York).

Name, Botanical and Common	Height	Color	Distance apart	Season	Remarks.
Ageratum Houstonianum, Floss Flower	8 in.	Purplish blue, white	6–9 in.	July, Aug.	Best blue hardy annual for edging.
Alyssum maritimum, Sweet Alyssum	8 in.	White	5 in.	July to frost	One of the best white, hardy annuals for edging.
Amarantus caudatus, Love-Lies-Bleeding	3 ft. +	Scarlet to yellow	15 in.	June	Tender; rather gaudy.
Antirrhinum majus, Snapdragon	1–4 ft.	Various	1–1½ ft.	July–Sept.	Sow in February for early bloom; cut-flower; hardy.
Arctotis grandis, African Daisy	1½ ft.	White, lilac	12–18 in.	June to frost	Hardy; petals white above, lilac beneath; blue center; daisylike.
Brachycome iberidifolia, Swan River Daisy	½–1 ft.	Pale blue or white	9–12 in.	July	Half-hardy; plant in heat for early bloom; pretty little plant.
Browallia demissa, Amethyst	1 ft.	Blue, white	9 in.	All summer	Tender; excellent planted among other annuals.
Calendula officinalis, Pot Marigold	12–18 in.	Orange, yellow, sulfur	12–18 in.	May to frost	Hardy; masses or borders.
Callistephus chinensis, China Aster	2 ft.	Various	9–12 in.	July to frost	Half-hardy; start indoors; partial shade or sun; cut-flower.
Celosia cristata, or Cockscomb	1 ft.	Various	9–12 in.	June to frost	Tender; cutting; border; moisture-loving.
Centaurea Cyanus, Bachelor's Button	1½–2 ft.	Blue-white, pink	12 in.	May to frost	Hardy; water and pick flowers, to prolong season of bloom.
Centaurea moschata, Sweet Sultan	2 ft.	White, yellow, purple	6–10 in.	June, through Aug.	Hardy; cut-flower; have bloom before hot weather.
Clarkia elegans, Clarkia	1–3 ft.	White, lilac, pink	8–12 in.	June–Sept.	Hardy; warm light soil; sun or partial shade.
Coreopsis tinctoria, Calliopsis	2 ft. +	Yellow, brown	8–10 in.	May to frost	Hardy; self-sows; good for cutting; sun.
Cosmos bipinnatus, Early Cosmos	4 ft. +	White, pink, crimson	12–15 in.	Late July to frost	Hardy; choose earliest varieties; not too rich soil.
Delphinium Ajacis, Annual Larkspur	1½ ft.	Various	6–12 in.	June, July	Hardy; sun; good for cut-flowers.
Dianthus chinensis, Chinese Pink	10–16 in.	Pinks, reds, combin	6–8 in.	July to frost	Hardy; scentless; really a biennial.
Eschscholtzia californica, California Poppy	15 in.	Yellow, pink, white	6–8 in.	July	Sun; sow early; do not transplant; tender.
Gaillardia pulchella, Blanket Flower	1–2 ft.	Crimson, red, yellow	10–12 in.	July to frost	var. picta, free-blooming; hardy; cutting.
Godetia amœna, Satin Flower	1–2 ft.	Red, white combin	8–12 in.	July–Oct.	Hardy; satiny luster.
Gomphrena globosa, Globe Amaranth	1–1½ ft.	Pink, purple, White, orange	1 ft.	July, Aug.	Hardy, cutting; masses; an everlasting.
Gypsophila elegans, Baby's Breath	1–1½ ft.	White	12 in.	July	Hardy; sow for succession of bloom; cut to combine with other flowers.
Helianthus annuus, Sunflower	2–10 ft.	Golden yellow	2–4 ft.	Aug. to frost	Hardy; background screen.
Helichrysum bracteatum, Everlasting	3 ft.	Deep red, white, yellow	10–12 in.	July to frost	Hardy; sun; gather flowers at night to preserve form.
Iberis amara, Candytuft	6–18 in.	White, crimson, carmine	6–9 in.	July to frost	Hardy; successive sowings two weeks apart prolongs season; sun.
Impatiens Balsamina, Lady Slipper	1–2½ ft.	Various	9–12 in.	July to frost	Half-hardy; sun; sandy loam.
Lavatera trimestris, Annual Mallow	2 ft.	Pink, white	12 in.	July	Hardy; sow early, May, where they are to grow.
Linum grandiflorum var. coccineum, Scarlet Flax	1–1½ ft.	Scarlet	8–10 in.	July	Half-hardy; glossy red; is attractive; not good when cut.
Lupinus hirsutus, Hairy Lupine	2–3 ft.	Blue, pink, white	6–8 in.	July–Aug.	Hardy; massing; cut-flowers; hairy.
Matthiola incana var. annua, Stock	1½ ft.	Various	6–12 in.	July–Sept.	Half-hardy; for early bloom start indoors; fragrant.
Nicotiana alata, Ornamental Tobacco	3–5 ft.	White	12–18 in.	July to frost	Hardy; start indoors; fragrant in evening; massing.
Nigella damascena, Love-in-a-Mist	1–2 ft.	Blue, white	10–12 in.	June–Sept.	Hardy; flowers surrounded by attractive foliage.
Papaver Rhœas, Shirley Poppy	2 ft.	Various	4 in.	June–Sept.	Hardy; sow very thinly September or April.
Papaver somniferum, Opium Poppy	2½ ft.	Various	4–5 in.	June–Sept.	Hardy; massing.
Petunia hybrida, Petunia	1 ft.	Various	1 ft.	June to frost	One of the most freely blooming annuals; half hardy.
Phlox Drummondii, Annual Phlox	1 ft.	Various	6–8 in.	June	Hardy; benefited by starting inside; massing in beds.
Portulaca grandiflora, Rose Moss	6 in.	Various	6–8 in.	July–Oct.	Hardy; sun; will thrive in dry soil.
Reseda odorata, Mignonette	1–1½ ft.	Reddish yellow	9 in.	July–Sept.	Hardy; fragrant; cutting; sandy soil.
Ricinus communis, Castor Bean	5–7 ft.	Green and bronze foliage	2½–ft.	July to frost	Half-hardy; tropical; screening; foliage plant.
Salpiglossis sinuata, Painted Tongue	1½ ft. +	Various	9–12 in.	July–Aug.	Half-hardy; sow indoors for early bloom; sun; rich soil.
Salvia splendens, Scarlet Sage	3 ft. +	Scarlet	8–12 in.	July to frost	Half-hardy; sun or half shade; start indoors, March; not too rich soil.
Scabiosa atropurpurea, Mourning Bride	2½ ft. +	Various	12–15 in.	Aug. to frost	Hardy; sow indoors for earlier bloom; sun; cut-flowers.
Schizanthus pinnatus, Butterfly Flower	2 ft. +	Yellow, lilac, rose, etc.	12 in.	July, Aug.	Hardy; masses; borders; cut-flowers.
Tagetes erecta, African Marigold	3 ft.	Golden yellow to sulfur	12–18 in.	July	Hardy; scented foliage; massing.
Tagetes patula, French Marigold	1–1½ ft.	Golden yellow to maroon	6–10 in.	July	Hardy; excellent edger.
Tagetes signata var. pumila, Dwarf Marigold	9–11 in.	Golden yellow	8–10 in.	Aug. to frost	Hardy; excellent edger.
Torenia Fournieri, Wishbone Flower	8 in.	Blue, white	8–12 in.	July–Sept.	Tender; urns and hanging-baskets.
Tropæolum minus, Tom Thumb Nasturtium	6 in.	Various	9 in.	July to frost	Half-hardy; cut-flowers; massing; sun.
Verbena hybrida, Verbena	1 ft.	Various	10–12 in.	July to frost	Hardy; sow indoors for early bloom; from cuttings less fragrant.
Zinnia elegans, Youth and Old Age	3 ft.	Red, yellow, magenta and combin	1 ft.	July to frost	Hardy; stiff but easily grown.

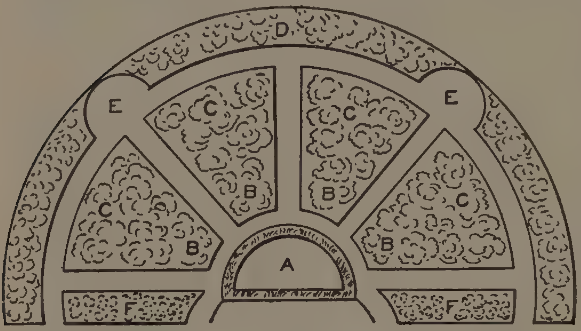
Planting-list of Hardy Herbaceous Perennials.—(A. C. Hottes, New York).

Name, Botanical and Common	Height	Color	Distance apart	Season	Remarks
Achillea Ptarmica, The Pearl	2 ft.	White	18 in.	June	Var. Pearl, double; confine, else it overruns garden.
Aconitum Napellus, Monkshood	3–4 ft.	Blue, white	10–15 in.	July, Aug.	Borders; root poisonous; partial shade; seeds difficult to germinate.
Adonis vernalis, Spring Adonis	6–9 in.	Yellow	12 in.	March	Do not disturb often; propagated by seed or division.
Althæa rosea, Hollyhock	4–6 ft.	Various	3 ft.	July–Sept.	Sun; plant in spring; single and double; standard background.
Anemone japonica, Japanese Anemone.	3–6 ft.	Rose, white	18 in.	Sept., Oct.	Excellent; one of best; sun or shade; standard fall border perennial.
Anthemis tinctoria, Golden Marguerite.	1 ft.	Yellow	12 in.	June to frost	Sun; divide annually; var. Kelwayi best.
Aquilegia chrysantha, Long-spurred Columbine	2–2½ ft.	Yellow	8–15 in.	June, July	Dainty and graceful; border; sun.
Boltonia latisquama	4–5 ft.	Blue, pink, violet	3–4 ft.	Late Aug.	Sun; remains in bloom several weeks; spreads rapidly.
Campanula carpatica, Harebell	6–9 in.	Deep blue	9–12 in.	July–Oct.	Edging border; sun; little bloom in fall.
Campanula Medium, Canterbury Bell.		Blue, white, pink.	1–1½ ft.	June.	Biennial; requires protection.
Campanula persicifolia, Peach-leaved Campanula	2–3 ft.	Blue or white	1–1½ ft.	June	Border; sun; rich soil.
Chrysanthemum coccineum, Pyrethrum	1–2 ft.	Various	12 in.	Aug. to frost	Needs protection in U. S.; light soil; sun; leave undisturbed two or three years.
Clematis recta, White Bush Clematis.	3–4 ft.	White	2½–3 ft.	June–Aug.	Border; dig deeply; give roots plenty of room.
Coreopsis grandiflora	1½–2 ft.	Golden yellow	15 in.	July	Cut-flower; border; keep seeds picked.
Delphinium formosum, Larkspur	4–5 ft.	Blue	2½ ft.	June–Sept.	Sun; rich, well-drained, rather heavy soil; if cut down after blooming will bloom again.
Dianthus barbatus, Sweet William	12–18 in.	Various	8–12 in.	June	Old-fashioned; still charming.
Dianthus plumarius, Grass Pink	8–12 in.	White to purple	8–12 in.	June	Rock-garden; beds; sun; rich soil.
Dicentra spectabilis, Bleeding Heart	15–24 in.	Rosy purple	15–18 in.	May, June	Warm soil; sun or shade; graceful; border; an old favorite.
Dictamnus albus, Gas Plant	12–15 in.	Purple, pink, white	12 in.	June	Remains a permanent border feature; will grow in partial shade.
Digitalis purpurea, Foxglove	1½–3 ft.	Pink and white	15 in.	June	Good foliage; sun or shade; var. gloxiniæflora best.
Eryngium amethystinum, Globe Thistle	3–4 ft.	Slate-blue	12–15 in.	July–Sept.	Attractive foliage and thistle-like heads; often dried for winter bouquets.
Filipendula hexapetala, Meadow Sweet.	12–18 in.	White	18 in.	June	Large clumps; fine foliage.
Gaillardia aristata, Blanket Flower	1 ft.	Yellow, maroon center	12–18 in.	June to frost	Keep flowers picked; sun.
Gypsophila paniculata, Baby's Breath.	2 ft.	White	18 in.	Aug.	Sun; fine flowers; excellent in bouquets.
Helenium autumnale, Sneezewort	4–6 ft.	Yellow	18–24 in.	Late Aug.	Border; sun.
Helianthus decapetalus var. multiflorus, Sunflower	4–6 ft.	Yellow	18–24 in.	Late Aug. Sept.	Good clumps; border; screening.
Hesperis matronalis, Sweet Rocket	3 ft.	White, magenta, purple	12–18 in.	July	Border; showy
Heuchera sanguinea, Coral Bells	12–15 in.	Crimson, white	12 in.	June	Sun; edging; resembles bishop's cap; long graceful spikes of bloom.
Iris germanica, German Iris	12–18 in.	Various	6 in.	June	Sun or half shade; wide range of adaptability.
Iris lævigata, Japanese Iris	18–30 in.	Various	6–12 in.	July	Requires abundance of water; sun.
Iris pumila, Dwarf Iris	6–8 in.	Purple	5–6 in.	June	Medium loam.
Iris sibirica, Siberian Iris	15–24 in.	Blue, white	6–12 in.	June	Moist soil.
Lobelia cardinalis, Cardinal Flower	2–3 ft.	Brilliant cardinal	12 in.	Aug.	Moist soil; sun or half shade.
Lychnis chalcedonica, Maltese Cross	3 ft.	Brilliant red	12 in.	July to frost	Showy; border; also called campion and lamp flower.
Lychnis Viscaria, German Catchfly	9 in.	Deep red, white	9–10 in.	June	Sun; long-lived.
Mertensia virginica, Virginia Cowslip	16 in.	Blue	Clumps	April	Leave undisturbed; foliage dies after flowering.
Monarda didyma, Bee Balm	3 ft.	Red, scarlet	12 in.	July	Sun; spreads rapidly.
Myosotis palustris, Forget-me-not	½–1 ft.	Blue, white	8–10 in.	May, June	Moisture; shade or sun if not dry; var. semperflorens is very good.
Œnothera missouriensis, Missouri Evening Primrose	6–9 in.	Yellow	8–10 in.	Aug.	Large flowers; showy.
Pæonia officinalis, Peony	2 ft.	Red, white	3 ft.	May	Heavy soil; sun; old-fashioned "piney."
Pæonia albiflora, Chinese Peony	3 ft.	Various	3–4 ft.	June	Sun; deep, rich soil.
Papaver nudicaule, Iceland Poppy	12–18 in.	White, yellow, orange	6–8 in.	May–Sept.	Edger; blooming intermittently through season.
Papaver orientale, Oriental Poppy	2–3 ft.	Red, scarlet	12–18 in.	June–Aug.	Mixed border; gorgeous colors; after flowering the plants rest and foliage dies down.
Pentstemon barbatus, Beard Tongue	1½–3 ft.	Light pink to carmine	9–12 in.	June, Aug.	Var. Torreyi; sun; rich; grown in masses.
Phlox paniculata, Hardy Phlox	3–4 ft.	Various	12–18 in.	June, July	Indispensable; clumps; choose good colors.
Phlox subulata, Moss Pink	12 in.	Lavender	8–12 in.	April	Excellent for rockery or border.
Platycodon grandiflorum, Chinese Balloon Flower	3–3½ ft.	Blue, white	12–18 in.	Aug.	Showy; border; cut-flower.
Polemonium cæruleum, Jacob's Ladder	1–2 ft.	Blue, white	12–18 in.	June	Likes moisture; sun or partial shade; border; finely cut foliage.
Rudbeckia laciniata, Golden Glow	4–6 ft.	Yellow	12–18 in.	Late Aug., Sept.	Excellent background; easily grown.
Sedum spectabile, Showy Sedum	15–18 in.	Pink	8–10 in.	Aug.	Showy; sun; rich soil.
Stokesia cyanea, Stokes' Aster	12–18 in.	Blue, white	12 in.	Aug.	Sun; light soil; masses; border; cut-flower.
Trollius europæus, Globe Flower	12–18 in.	Yellow	12 in.	May, June	Moist heavy loam; buttercup-like flowers; best in half shade.
Viola cornuta, Horned Violet	6–8 in.	Blue, white	12 in.	May	Masses; rich soil.
Yucca flaccida, Hardy Yucca	5 ft.	White	2 ft.	June	Transplant early spring; sun; light soil.

Note.—In the column "distance apart," the distance indicated is for first year; nearly all plants will need frequent division of clumps, placing them at greater distances apart.

radiating from a common center. Such beds provide the greatest amount of growing room with the least waste, and they bring all parts of the garden into view, without the defect of nearby beds shutting out the view of those in the rear. Such a garden is shown in Fig. 2038, with turning-places and outlooks at EE.

If the home flower-garden comprises the whole of the floral planting and no other space is devoted to shrubbery and the more robust kinds of perennials, then these radiating beds furnish the very best form in which to combine them with the landscape garden proper. Starting from a central point, A, which may be conspicuous by a pool, a bit of sod with table and seat or any garden furnishing, the beds, which may be as narrow as 1 foot at the point, widen gradually as they recede until, at the circumference, they attain considerable width; these rear parts are excellent for the planting of shrubbery and tall perennials, and shrubs may extend upward through the center of the rear parts of the beds; tall perennials may be massed at the sides and in front, lower perennials border these, and annuals and edging plants fill out the remainder of the ground, in this way furnishing a massed planting which is very attractive and also economical of space. The diagram (Fig. 2038) is a very good example of this manner of platting, and it may be adopted in its entirety or simplified by omitting the outer circle and the two short beds in front.



2038. A serviceable plan for a home flower-garden.

When economy in labor is of moment, it will be well to choose those plants whose manner of growth is clean and neat, rather than those that tend to spread and so require much cutting and restraining. Lilacs, for example, require constant grubbing out, while the lespedeza has an attractive erectness and cleanness of manner and requires no pruning or restraint; this, also, is true of the altheas and spireas in the main, while the deutzia is easily kept to the single plant if desired.

Lilies, which do their best when planted among shrubbery and perennials, should be used abundantly in the home-garden, especially the candidum and auratum lilies. For summer cut-flowers, few things equal in effectiveness and usefulness the gladiolus; and as this flower is at its best when interspersed among more generously foliaged plants, it may be worked in among tall perennials to good advantage. Perennial poppies are one of the valuable garden assets and, once established, continue to give satisfactory returns for years. They combine effectively with the Shasta daisies, and are specially effective against the green backgrounds of taller plants. The dictamnus is valuable and should find a place in the home-garden, as once established it is practically everlasting; and its manner of growth is so erect and neat, its bloom so satisfactory and attractive that it is well worth adopting.

A garden laid out as indicated and planted in the rear and central parts with permanent things, leaves abundant room in front and along the margins for annual plants and for experiments in novelties from year to year. It will have its shady and sunny spots which may be utilized for plants requiring special conditions of exposure.

Certain old garden favorites among the annuals will be much in evidence, but a study of the catalogues of the leading florists will show vast improvements in type which may be adopted without in any way detracting from the old-time sentiment of the flowers. Asters and pansies, especially, show this advancement, and petunias are much superior to the small kinds of a few years ago. In purchasing seed of these flowers it is economy to buy the most expensive, as the results well repay the extra outlay. From 25 to 50 cents a packet for pansies and petunias is none too much if one would secure notable flowers.

The home-garden should be beautiful and interesting from early spring until frost, and to secure this result one must plant freely along the margin of the beds of spring-blooming bulbs—crocus, tulips, hyacinths, narcissi and the like. These bulbs do admirably planted in long, triple rows, and the space between them may be filled in summer with candytuft, ageratum, schizanthus, Drummond phlox, verbena, petunia.

Sufficient plants that bloom late in summer and in autumn should be supplied to make the garden attractive at this time. Anemones are the most charming of autumn flowers, hardy chrysanthemums bloom well into November, tritomas or kniphofias are a blaze of color for weeks. By judicious planting there need be no dearth of color in any season.

Preparing the ground for the flower-garden.

The preparation of the ground, especially when the planting is to be of a permanent character,—that is of shrubbery, perennials and hardy bulbs,—is of great importance, as any defects in quality of mechanical condition of the soil will not be easily rectified, once the planting is accomplished.

Good drainage is the first consideration, as this must be performed before any platting or bed-making is attempted. When the lay of the land makes for a natural removal of surplus moisture, or the soil is sandy and underlaid with gravel, no artificial drainage will be required; but when the soil is cold and sour and retentive of too much moisture it will be necessary, for the best results, to lay two or more courses of porous drain-tile underneath the plot.

If the garden is large enough to admit of an initial plowing, this way of preparing the soil may put it in better mechanical condition than spading, although, of course, after the beds are laid out and paths established, spading will be the only feasable method of working the ground. When the soil is naturally good, as in breaking up a piece of sod land or in a well-fertilized garden spot, it will be necessary only to spade or work up the beds, incorporating a liberal quantity of old well-rotted manure. A very satisfactory way of working manure into beds is to begin at one side of the bed and spade one row, laying the soil one side so as to leave an open trench; fill this trench full of manure and spade the next row on top of this, and so continue till the entire area is covered. This buries the manure well beneath the surface and effectively prevents the germination of weed seeds; at the same time the manure deep in the soil holds the moisture and brings the roots well down beneath the surface where they remain cool and moist. See p. 1739, trenching.

In beds that are to be worked over but not fertilized the second summer, it is not desirable to turn the soil over in spading as this throws the manure back to the surface; but sufficiently satisfactory results are secured by thrusting the spade well down into the ground and turning it around, but not lifting it out. A bed worked over in this way will be in excellent condition and less disturbance and cutting of the roots will result.

A garden planted to shrubs and perennials may safely be left undisturbed for three years, providing a good annual stirring of the soil is given in early spring followed by sufficient tillage to establish a dust-mulch throughout the dry weather. Getting down on hands and knees and working around each individual plant with a trowel has many advantages, as it puts one more intimately in touch with the plant than is possible with hoe and spade. Many ambitious little shoots succumb to the onslaught of a too vigorous hoe, that might have been saved by a closer inspection. The presence of insect enemies about the base of the plants is likely to pass unnoticed until much damage is done, when only a standing cultivation is practised; so, one intimate acquaintance with each inmate of the garden is advised at least once a year, preferably in early spring.

For the remainder of the summer, dependence may be placed on any one of the various forms of hoes, preferably the scuffle-hoe, as by the use of this tool one can work closer to the stem of the plants, slipping beneath the leaves and recumbent foliage with little damage. It produces the most perfect dust-mulch of any tool and as it is used walking backward no footprints are left on the soil to press a weed back into the ground where it may grow again, as is the case with a wheel-hoe or most hand-hoes, and last, it is the tool best adapted to a woman's use and with it she can accomplish a large amount of labor with little fatigue. A good trowel is essential. In buying this everyday implement, the gardener should choose one in which the blade and handle are in one piece of steel, for a handle riveted or secured to the blade is always unsatisfactory and of short duration. Pruning shears that open easily and fit the hand well are also necessary when shrubs or roses are cultivated. These three articles, together with a spade and rake are about all the indispensable tools aside from a good wheelbarrow and one or more baskets of convenient size.

When the garden plat is confined with an ornamental wooden fence, painted white as is so much the custom, a good effect is gained by planting tall-growing shrubs in the rear to reach over the fence, furnishing a charming background of bloom and greenery.

Tall-growing shrubs that make their growth mostly at the crown are especially desirable, as for example, the dogwood, flowering thorns, red-buds, tree lilacs and the tamarix. Shrubs which bloom from the ground up are wasted in the flower-garden. Altheas, syringas, deutzias, spireas, symphoricarpos, Tartarian honeysuckles, weigelas, snowballs and the like need an open place in which to display their merits to the best.

As the buying of any great quantity of perennial plants calls for a considerable initial outlay, it is both economical and interesting to grow them from the seed. The seeds may be started in hotbeds in early spring and transplanted into the beds where they are to grow as soon as large enough; or, what may be the better way for many kinds, they may be sown in long rows in the vegetable-garden, where they will receive the same cultivation as the vegetables and be transplanted the following spring. Oriental poppies do especially well under this treatment. Shasta daisies and delphiniums should be planted, but physostegias, hibiscus, aquilegias, achilleas, sweet Williams, dianthus, digitalis, gauras, sunflowers, hollyhocks, may be produced by the hundreds at a very trifling expense.

Annuals that are desired merely for cutting may also be grown in the vegetable-garden to advantage. Asters, sweet peas, cosmos, arctotis, annual larkspurs, centaureas, cornflowers, gaillardias, all the everlastings, may very profitably be relegated to this economic culture and so leave room for more permanent things in the garden proper.

IDA D. BENNETT.

KITCHÍNGIA (personal name). *Crassulàceæ.* Succulent glabrous perennial herbs, allied to Bryophyllum but with small calyx and diverging carpels: sts. flexuose, bearing many opposite sessile or stalked fleshy crenate lvs.: fls. large for the plant, bright red, terminal, often in loose racemes, the parts in 4's; calyx-segms. as long as tube; corolla-tube campanulate or tubular, sometimes larger in middle, with 4 short lobes; stamens 8: carpels 4, free, making small many-seeded follicles.—Species 10, in Madagascar. *K. uniflòra,* Stapf, is an attractive prostrate sedum-like plant, rooting at the joints: lvs. obovate and obtuse, less than 1 in. long, bright green: fls. solitary or 3 together, bright red, the corolla-tube narrowed at both apex and base, about 1 in. long and half as thick; stamens polymorphic. B.M. 8286. R.H. 1913, p. 177.—A recent species, suitable for temperate conditions under glass.

L. H. B.

KLEÌNIA. Of the three genera of Compositæ of this name, two are referred to Porophyllum and Jaumea, but the trade names will be accounted for under *Senecio.*

KLÙGIA (Dr. Fr. Klug, German zoölogist). *Gesneriàceæ.* About 4 blue-fld. herbs, rooting at the base and more or less succulent, suitable for growing in the greenhouse. Lvs. alternate, or sometimes nearly opposite and one of the pair reduced to very small size, the sides of the lf. unequal, many-nerved, sinuate or nearly entire: fls. opposite the lvs. or terminal, small and pendulous, short-stalked; calyx 5-angled or 5-winged, one wing often larger than the others, the lobes of calyx 5; corolla-tube cylindrical, 2-lipped, the upper lip very small and the lower rounded or somewhat 3-lobed; stamens 4, perfect: fr. a 2-valved caps. included in the calyx. India, and 1 species in Mex. *K. Notoniàna,* A. DC. Quick-growing herbaceous annual, 12–18 in., more or less puberulent: lvs. petiolate, ovate, acuminate, 5–8 in. long: corolla-tube white, ½in. long; large lower lip blue, with yellow at the base; calyx-lobes short and triangular, and one wing larger. India, 2,000–5,000 ft. altitude; variable. Blooms under glass, Jan. to summer. G.C. III. 19:237. *K. zeylánica,* Gardn., differs in the long-acuminate calyx-lobes and the wings of calyx nearly equal. Ceylon. B.M. 4620 (as *K. Notoniana*).

L. H. B.

KNIPHÒFIA (Johann Hieronymus Kniphof, 1704–1765, professor at Erfurt). Syn., *Trítoma. Liliàceæ.* TORCH-LILY. RED-HOT-POKER PLANT. FLAME-FLOWER. Excellent showy perennial herbs grown in the open (some species under glass), with spikes or racemes of long, drooping red and yellow (rarely white) flowers.

Herbs with abundant radical lvs. and stout, simple naked scapes or peduncles, the thick roots from a short vertical rootstock, mostly stemless but a few species with a short caudex below the crown of lvs.: fls. many, in a spike-like raceme or dense head-like spike, on short articulated pedicels; perianth funnel-shaped or cylindrical, the tube long and the nearly or quite equal segms. small and mostly broad; stamens 6, in two lengths, equaling or exceeding the perianth; ovary 3-celled, bearing a filiform style and capitate stigma: fr. a short 3-valved caps.—Species probably 70, in Trop. and S. Afr. in the tropical regions mostly from high elevations. The genus is rich in good native forms, many of which are scarcely known in general cult., and it is to be expected that important horticultural developments will arise in the future. Accounts of the species described to those dates will be found in Flora Capensis (1896–7) and Flora Tropical Africa (1898) in the treatments by Baker, from which the present descriptions have been largely drawn. These descriptions are made mostly from wild plants and therefore may not apply to garden forms, which are very likely to be hybrids.

The kniphofias are among the most showy of border plants. They are essentially autumn bloomers, but some of the newer kinds are nearly continuous bloomers from midsummer. The common kinds are hardy south of Philadelphia when well covered in winter, but in the North it is usually safer to dig up the plants in November, place them in boxes with dry earth, and store them in a cellar in winter. In spring place them in a warm, sheltered, well-drained spot, perhaps with a background of shrubbery to set off the flowers. Some of the recent species from tropical Africa are treated as greenhouse or warmhouse subjects. In general cultivation the prevailing species is *K. Uvaria.* This is nearly hardy North, has sword-shaped leaves 2 to 3 feet long, and several scapes 4 or 5 feet high surmounted by a spike 4 to 8 inches long composed of perhaps 100 tubular, drooping flowers, each 1 inch or more long, and fiery red. It has perhaps a dozen varieties with Latin names and twice as many with personal names. Most other species have much the same general effect, and recent variations and apparent hybrids have greatly extended the blooming season and the range of color and form. For producing mass-effects, the torch-lilies are among the most striking subjects, the brilliant flowers producing a flame of color. Clumps in open sunny places are particularly emphatic.

The miniature-flowered torch-lilies are excellent for planting in small beds and near the front borders and also for cutting. They begin to bloom as early as June. The plants are mostly small, the racemes not so massive, and the flowers small and short. It is probable that such species as *K. Nelsonii, K. pauciflora, K. rufa, K. breviflora* have entered into them.

Under cultivation, the kniphofias appear to hybridize very freely through the agency of bees, and seedlings therefore may not be true to the parent from which they came. The result is that there is much confusion in the literature of the genus, and it is often very difficult to trace the original species-forms.

They grow readily from seeds, and novel forms are likely to be secured from the mixed garden parentage. The plants should bloom freely the second year, and often the first year. The usual method of propagation is by division; the caulescent kinds, however, may not produce offsets or divisible parts readily unless they are headed back or cut off to make them spread. Kniphofias are often classed by dealers as bulbous plants, though they have only a short rhizome and numerous, clustered, thickish root-fibers. Old but vigorous plants of the *K. Uvaria* kind divide easily, and give large strong pieces.

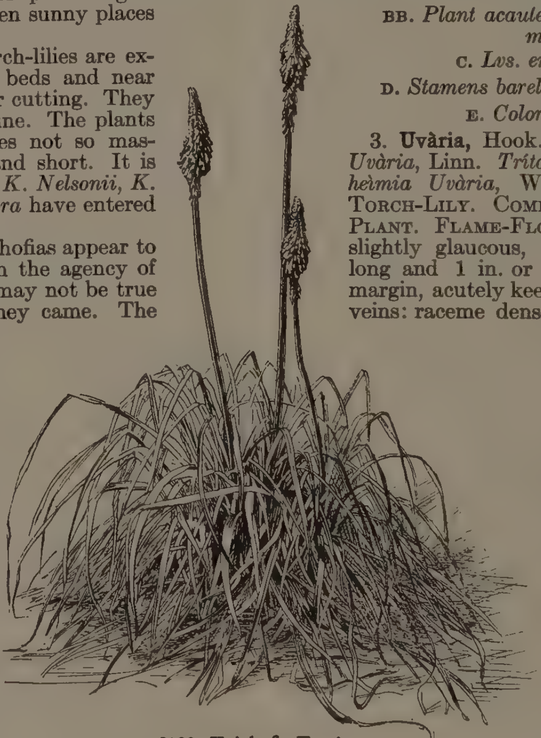
A. *Perianth long, an inch or more.* (*Nos. 1–13.*)

B. *Plant caulescent* (*a st. or caudex below the lf.-crown*).

1. **cauléscens,** Baker. Plant with a thick st. below the lvs., 6–12 in. long: lvs. very glaucous, sword-shaped-acuminate, broadly channelled, not acutely keeled on the back, 2–3 ft. long, 2–3 in. wide, margin serrulate: spike about ½ ft. long, 3 in. thick; lower fls. yellow, upper ones red; segms. broad, ovate and obtuse, very short; stamens and style somewhat exserted. Cent. Cape region. B.M. 5946. G.C. III. 6:564. R.H. 1887:132 (as *Tritoma caulescens*). Gn. 41:536; 78, p. 502. G. 36:83. Gn.W. 16:443. G.M. 57:555.

2. **Nórthiæ,** Baker. St. short, 2–3 in. diam.: lvs. 30–40, in a dense rosette, 4–5 ft. long and 5–6 in. broad, lance-acuminate, channelled on the face, not sharply keeled, margins serrulate: raceme or spike 1 ft. and more long, very dense, on a peduncle shorter than the lvs.; fls. 1 in. long, the lower ones yellow and the upper ones red toward the tip; segms. small and ovate; stamens becoming much exserted. Coast region. S. Afr. B.M. 7412. G.C. III. 39:100. Gn. 73, p. 480.



2039. Kniphofia Uvaria.

BB. *Plant acaulescent* (*no caudex below the mass of lvs.*).

C. *Lvs. ensiform-acuminate.*

D. *Stamens barely exserted in full anthesis.*

E. *Color of lvs. dull green.*

3. **Uvària,** Hook. (*Alòe Uvària,* Linn. *Áletris Uvària,* Linn. *Trítoma Uvària,* Ker-Gawl. *Veltheìmia Uvària,* Willd. *K. alooìdes,* Moench). TORCH-LILY. COMMON POKER PLANT. POKER-PLANT. FLAME-FLOWER. Figs. 2039, 2040. Lvs. slightly glaucous, ensiform-acuminate, 2–3 ft. long and 1 in. or less broad, scabrous on the margin, acutely keeled, with 30–40 close vertical veins: raceme dense, often 6 in. long, 2½–3 in. thick, on a peduncle as long as the lvs.; upper fls. bright red, lower ones yellow; perianth cylindrical, to 1½ in. long; segms. ovate and obtuse; stamens in the lower fls. barely exserted. General Cape region. F.S. 13:1393. B.M. 758; 4816.—The following varieties with Latin names are in the trade and usually advertised as apparent species under Kniphofia or Tritoma. They may be all more or less distinct horticulturally. Var. **carnòsa,** in Gn. 19:548, with the fls. opening from the top instead of the bottom, and with red filaments and yellow anthers. Leichtlin intro. it about 1881 and said it grew 1½–2 ft. high, the apricot-red of the fls. toned down by a glaucous bloom. (Cf. No. 17.) Var. **floribúnda** is early-flowering. Var. **glaùca** is apparently a trade name. Var. **glaucéscens** is figured in Gn. 36:458 with a spike 9 in. long, of "vermilion-scarlet fls. changing to a more orange color; one of the freest bloomers. Intro. 1859." Foliage somewhat glaucous. Var. **grandiflòra,** one of the earliest improvements on the type: 2–3 ft. high. Var. **grándis.** Large-fld.; fls. red and yellow, 5 ft. The plant in the trade as *K. Pfitzeri* probably belongs here; see also suppl. list, p. 1755. Var. **nóbilis** is said by Carrière, R.H. 1885:252, to have shorter and stricter lvs. than var. *Saundersii,* the spikes more ovoid, the fls. uniformly red and less deflexed. Lvs. not glaucous. Gn. 55, p. 167. Var. **Saùndersii,** in R.H. 1882:504, is shown with "red-orange fls." in an elliptical spike and said to grow 6 ft. and more

high. It grows 4-6 ft. high in rich soil, the peduncles less rigid than in *K. Uvaria* (blooming late) with cylindrical spikes 18–24 in. long and fls. often ½in. across. Gn. 71, p. 492. See var. *maxima*, below.

Baker's treatment of the botanical varieties (under *K. alooides*) is as follows (Fl. Capensis, VI, p. 283):

Var. **máxima** (*Trítoma grandiflòra*, Hort. *T. Saùndersii*, Carr.). More robust: lvs. 4–5 ft. long, 1 in. wide: raceme and fls. longer; stamens more decidedly exserted. B.M. 6553 (fls. yellow, more or less tinged red). R.H. 1882:504 (colored like the type).

Var. **nóbilis** (*Trítoma nóbilis*, Guill.). Still more robust: scape including raceme sometimes 6–7 ft. long; fls. 1½ in. long. R.H. 1885:252.

Var. **serótina,** Hort. A late-flowering form with slender perianth 1¼ in. long and distinctly exserted stamens. Baker also mentions var. **carnòsa, glaucéscens** and **refúlgens** without discrimination. Other varieties with Latin names are mentioned in Gn. 36:458. *K. prǽcox*, Baker, is probably not in cult.: fls. sometimes in summer and sometimes in autumn.

4. **Roòperi,** Lem. Lvs. ensiform-acuminate, 4 ft. long, and to 1½ in. broad, scabrous on the margin, acutely keeled, glaucous: raceme to 6 in. long, very dense, on a stout stiff peduncle as long as the lvs.; fls. paler than in *K. Uvaria* and later; perianth cylindrical, to 1½ in. long, the segms. ovate and obtuse; stamens at length just exserted. Coast region, S. Afr. B.M. 6116. J.F. 4:362.—The plant grown under this name is likely not to be the true botanical species here described.

EE. *Color of lvs. bright green.*

5. **Búrchellii,** Kunth. Lvs. ensiform-acuminate, 2–3 ft. long, ½–¾in. wide, sharply keeled, 15–20 ribs each side of midrib, smooth on the margin: spike 6–12 in. long, on a stout peduncle 3 ft. high; fls. bright yellow, much tinged with red when young; perianth somewhat cylindrical, to 1½ in. long, the segms. as long as broad and ovate; stamens at length just exserted. S. Afr. B.R. 1745 (as *Tritoma Burchellii*).—Probably the true *K. Burchellii* is not now in commerce.

6. **longicóllis,** Baker. Lvs. ensiform, sharply keeled, 2 ft. long and 1 in. broad at base, smooth on margins: raceme dense and short, on a slender peduncle 1½ ft. long: fls. lemon-yellow tinged orange-yellow when young, on very short pedicels; perianth somewhat or nearly cylindrical, to 1½ in. long, constricted above the ovary, the lobes small and ovate; stamens and style at length short-exserted. Natal. Gn. 59, p. 96; 63, p. 92. Gn.W. 20:120.

DD. *Stamens prominently exserted.*

7. **sarmentòsa,** Kunth. (*Áletris sarmentòsa*, Andr.). Lvs. ensiform-acuminate, 2–3 ft. long and to 1 in. broad, glaucous-green, sharply keeled, about 12 ribs either side the midrib: raceme cylindrical, dense, 6–12 in. long, on a stout peduncle equaling the lvs.; upper fls. red, the lower yellow or yellow tinged red; perianth cylindrical, to 1 in. long, the segms. broad, ovate and obtuse; stamens and style at length exserted to about ½in. S. Afr. B.M. 744.—It produces underground shoots or offsets.

8. **primúlina,** Baker. Lvs. many, ensiform, 3–4 ft. long and ½–1 in. broad, toward base sharply keeled, smooth on margin: raceme dense, oblong, 3–4 in. long, on a stout and stiff peduncle as long as the lvs.; fls. pale yellow; perianth nearly cylindrical, 1 in. long; segms. small and ovate; stamens and style much exserted. Eastern region. S. Afr. G. 32:299.

CC. *Lvs. linear.*

9. **triangulàris,** Kunth. Lvs. narrow-linear, rather rigid, erect, 1 ft. long, nearly triquetrous, margins smooth: raceme dense, 12–18 in. long, on a slender peduncle 1–1½ ft. long; fls. all yellow; perianth 1 in. long, cylindrical; segms. ovate-oblong and obtuse, longer than broad; stamens and style not exserted. Central region, S. Afr.

10. **Nélsonii,** Mast. Lvs. narrow-linear (the old ones persisting as weak fibers), 1½–2 ft. long, with a thick midrib, rounded and 3-nerved on the back, and recurved serrulate edges: raceme dense, oblong, 2–3 in. long, on a peduncle as long as the lvs.; fls. bright scarlet sometimes tinged orange, all deflexed at expansion, on very short pedicels; perianth cylindrical, 1¼ in. long and narrow; segms. oblong and small; stamens more or less in two series, much shorter than perianth. Kalahari region, S. Afr. G.C. III 11:561; 39:82. Gn. 50, p. 400; 55:166.—It is probable that *K. Nelsonii* is not represented in the garden plants under this name. A hybrid between *K. pauciflora* and *K. Macowanii* has passed under this name, but it is now given the name *K. kewénsis*, N. E. Br.: fls. yellow.

2040. Kniphofia Uvaria.

11. **Macówanii,** Baker (*Trítoma rigidíssima* and *T. maroccàna*, Hort.). Dwarf: lvs. linear, erect and rigid, to 2 ft. long, 3–5 veins either side the midrib, with a thickened scabrous margin: raceme very dense, 2–4 in. long, on a slender peduncle 1–2 ft. long; fls. bright yellowish to orange-red; perianth cylindrical, 1 in. long; segms. ovate and obtuse, reflexed; stamens not exserted. S. Afr. B.M. 6167. R.H. 1879:390. G.C. III. 39:83.—*K. corállina*, Hort., R.B. 19:25 (1893), a hybrid between this species and *K. Uvaria* was raised by Deleuil, of Marseilles: it grows 18–24 in. high and bears ovoid spikes of coral-red fls. all summer and fall: said to be good for cutting. *K. mèdia Macówanii*, Hort.: "a hybrid between *K. aloides grandiflora* and *K. Macowanii*. This is an earlier blooming sort than either of its parents, as dwarf as *K. Macowanii* and much earlier and more brilliant."

12. **natalénsis,** Baker. Lvs. linear, 1½–2 ft. long to ⅓in. broad, with 10–12 veins either side midrib, margin thickened: raceme not very dense, 6–8 in. long, on a peduncle 2–3 ft. long; fls. mostly yellow; perianth nearly cylindrical, about 1 in. long; segms. ovate; stamens as long as perianth; style at length exserted. S. Afr.—Variable.

13. **longiflòra,** Baker. Much like *K. sarmentosa*, differing in the perianth being twice longer and the stamens scarcely exserted: lvs. linear, 2 ft. long, flaccid, green, sharply keeled, ¾in. wide toward the base: raceme dense, oblong, 3 in. long, on a stout peduncle that is 3 ft. and more tall; fls. yellow-red, strongly deflexed; perianth cylindrical, slender, curved, 1½ in. long; segms. ligulate and obtuse; stamens in two series included; style long-exserted. Natal probably

AA. *Perianth short, mostly ¾in. or less long.*

B. *Fls. (perianth) not more than ⅓in. long.*

C. *Color of fls. white, when open.*

14. **modésta,** Baker. Lvs. linear, rigid, 1½ ft. long, sharply keeled: raceme moderately dense and spike-like, secund or 1-sided, 4–7 in. long, on a slender peduncle as long as the lvs.; fls. ⅓in. long, the perianth cylindrical, and the segms. ovate; anthers at length just exserted. Griqualand, S. Afr.—Probably not in cult., the next having been confused with it. In the original description the fls. are described as yellow.

15. **spársa,** N. E. Br. A much stouter plant than *K. modesta,* with lvs. 2–2½ ft. long: peduncle 2½–3½ ft. high, bearing a spike 9–18 in. long; fls. reddish or reddish; brown in bud but white when expanded, rather laxly scattered and directed to all sides. Natal. B.M. 7293 (as *K. modesta*).

CC. *Color of fls. yellow.*

16. **breviflòra,** Harvey. Lvs. linear, not rigid, 12–18 in. long and very narrow, strong ribs about 5, margin scabrous: raceme dense, 1½ in. or less long, on a slender peduncle as long as the lvs.; fls. yellow, on very short pedicels; perianth cylindrical, ¼in. long; segms. ovate and obtuse; stamens as long as perianth. S. Afr.

BB. *Fls. (perianth) ⅓–¾ in. long.*

C. *Shape of perianth funnelform (flaring at the end).*

D. *Stamens exserted more than the length of perianth.*

17. **comòsa,** Hochst. Rootstock thick and short, with copious roots: lvs. many, linear, bright green, to 2 ft. and more long, sharply keeled, edges smooth: raceme very dense, oblong, 3–4 in. long, on a peduncle equaling the lvs.; fls. bright yellow, deflexed, ½in. long and funnel-shaped but dilated suddenly at the middle; segms. very obtuse; filaments red; anthers yellow, long-exserted. Nile Land. B.M. 6569.—This is perhaps more conspicuous by reason of its mass of stamens than the outline of the spike. It is doubtful whether the true *K. comosa* is the same as the cult. plant of that name. Perhaps *K. comosa* and *K. Leichtlinii* of gardens are forms of one species. In the true or botanical *K. comosa* and *K. Leichtlinii,* the spikes are sometimes 2 or 3 on the peduncle; when there is only 1 spike, the uppermost fls. open first, thus reversing the usual order in the kniphofias; when there are lateral spikes, they open from below upward. G.C. III. 56:410.

18. **Leìchtlinii,** Baker. Plant with many slender root-fibers: lvs. many, linear, strongly keeled, 3–4 ft. long and ½in. wide toward base, edges smooth: fls. bright yellow; perianth narrowly funnel-shaped, becoming ¾in. long; segms. ovate, very obtuse; stamens and style distinctly exserted (about 1½ times length of perianth): scape speckled with red, sometimes bearing a bract 4–5 in. long, as long as the lvs., the raceme very dense and 3–4 in. long. Nile Land. B.M. 6716. R.H. 1884, p. 556. Var. **aùrea,** Hort. Spike or raceme broad and about 1 ft. long; upper unopened fls. soft orange-red and the lower ones soft yellow.

19. **multiflòra,** Wood & Evans. Lvs. 3–6 ft. long, 1 in. broad in middle, long-acuminate, deeply channeled above, strongly keeled, with many strong nerves, margin serrulate, stiffish, bright green above and somewhat glaucous beneath: spike 2 ft. long, dense, cylindric and narrow (1½–2 in. diam.), on a stout peduncle as long as lvs. or shorter; fls. white or suffused with green (buds yellowish), numerous, erect, produced very late; perianth ⅔in. or less long, swollen at base, narrow-funnelform; segms. small and rounded, erect; filaments white, almost twice the length of the perianth. Natal, 5,000–6,000 ft. B.M. 7832. G.C. III. 45:196; 54:356. Gn. 77, p. 587.

DD. *Stamens exserted, not exceeding the length of the tube.*

20. **pauciflòra,** Baker. Lvs. few, linear and rigid, 1–1½ ft. long, margin thickened and smooth: raceme lax, 2–3 in. long, on a slender peduncle 1½–2 ft.; fls. pale yellow; perianth narrow-funnelform, ¾in. long; stamens shortly exserted. Eastern region. S Afr. B.M. 7269. G.C. III. 12:65; 39:101.

21. **pùmila,** Kunth (*Trítoma pùmila,* Ker-Gawl). Lvs. linear, to 2 ft., glaucous, sharply keeled, 10–12 veins either side of midrib: raceme very dense, 3–4 in. long, on a peduncle equaling the lvs.; fls. red, or yellow to red; perianth narrow-funnelform, to ¾in. long, suddenly dilated above base; segms. ovate and obtuse; stamens and style exserted to ⅓in. S. Afr. B.M. 764.

CC. *Shape of perianth nearly or quite cylindrical: fls. yellow or yellow-red.*

D. *Lvs. very narrow (½in. or less broad).*

22. **grácilis,** Harvey. Lvs. linear ⅙in. broad, 1½–2 ft. long, margin smooth, 5–6 veins either side the midrib: raceme dense, 2–3 in. long, on a peduncle as long as the lvs.; fls. pale yellow; perianth about ½in. long, with a very slender tube and dilated throat; segms. oblong; the longer stamens and the style exserted. Eastern region, S. Afr. R.B. 39:227.

23. **citrìna,** Baker. Lvs. many, linear, 1½–2 ft. long and ⅓in. to perhaps ½in. broad toward the base, acutely channelled down the face, slightly scabrous on the edge: raceme oblong, dense, 2–3 in. long, on a slender peduncle shorter than the lvs.; fls. pale yellow; perianth subcylindrical, about ¾in. long; segms. small and ovate; stamens and style much exserted. Coast region, S. Afr.

24. **rùfa,** Leicht. Small: lvs. few, linear, 12–18 in. long and ⅓in. broad toward base, firm and green, sharply keeled on back, tapering to a long point, margin smooth: raceme lax, 4–6 in. long, on a moderately stout peduncle as long as the lvs.; lower fls. primrose-yellow and upper ones tinged red, drooping; perianth cylindrical, ¾in. long; segms. orbicular, spreading; stamens and style at length exserted. Natal. B.M. 7706. G.M. 47:562.—Blooms early and for a long season; a good border plant.

DD. *Lvs. broader (¾–2 in., toward base).*

E. *Stamens short-exserted.*

25. **Túckii,** Baker. Lvs. ensiform, bright green, 1–1½ ft. long, ¾in. wide, margin serrate: raceme very dense, 5–6 in. long, on a peduncle shorter than the lvs.; fls. yellow, tinged bright red when young, deflexed; perianth subcylindrical, ⅝in. long; segms. short, ovate and obtuse; stamens shortly protruding. Central region, S. Afr.—One of the hardiest.

EE. *Stamens much or prominently exserted.*

26. **Tỳsonii,** Baker. In character, between *I. pumila* and *I. sarmentosa:* lvs. linear, 3–4 ft. long and at base ¾in. broad, tapering to a long point, sharply keeled: raceme very dense, 6 in. long, on a peduncle that equals the lvs.; fls. red-yellow; perianth cylindrical, ¾in. long; segms. nearly orbicular; stamens protruding to ⅓in. or less. Eastern region, S. Afr. Gn. 77, p. 538.

27. **foliòsa,** Hochst. (*K. Quartiniàna,* A. Rich.). Lvs. densely tufted, 2–3 ft. long and to 2 in. broad, ensiform, acuminate, sharply keeled: raceme dense, oblong, on a very stout peduncle equaling the lvs.; fls. yellow; perianth cylindrical, about ¾in. long; segms. small, ovate and obtuse; stamens much exserted. Transvaal. B.M. 6742.

K. elménsis, Hort. Garden hybrid (Sprenger, Naples) between K. pauciflora and K. rufa.—*K. erécta,* Hort. Remarkable hybrid: spike conical before anthesis, the buds spreading horizontally, but as the spike develops the fls., beginning with the lowermost, take an erect position, at the same time the axis of the spike elongating, finally all the fls. becoming erect: fls. brilliant orange-scarlet, fading from below upward, never expanding. G.C. III. 56:410.—*K. excélsa,* Hort. Garden hybrid, parentage not recorded: remarkable for enormous size and almost campanulate fls.—*K. Goldélse* Hort. Seedling from K. Nelsonii and K. pauciflora: fls. pure yellow. G. 32:29.—*K. hýbrida,* Hort., is a trade name used to include varieties with personal names, of miscellaneous or unknown paren tage. The new "everblooming" poker-plants are likely to be listed under this name.—*K. Pfitzerii*, Hort. (K. grandiflora multiflora, Hort.). Described as in bloom from Aug. to Oct., with spikes standing 3–4 ft. high, the fls. rich orange-scarlet.—*K. ruvària*, Hort. Garden hybrid between K. rufa and K. Uvaria (Sprenger, Naples).—*K. sulphùrea*, Hort. Free-flowering, sulfur-yellow.—*K. trícolor*, Hort. Small-fld.; buds opening cochineal-red, changing to canary-yellow and then to sulfur-white.—*K. vomerénsis*, Hort. Garden hybrid (Sprenger, Naples) between K. pauciflora and K. rufa.—*K. Woòdii*, Campbell. Resembles K. modesta, but is stouter and there are a few spines on the lvs.: peduncle 3½ ft., the raceme 9 in. long; fls. ½in. long, pale cream-color. S. Afr.

Wilhelm Miller.
L. H. B.†

KNOWLTÒNIA (Thos. Knowlton, 1692–1781, curator of the botanic garden at Eltham, England). *Ranunculàceæ.* By some referred to Anemone, but differs in having 5 sepals and numerous petals, and the carpels soft and fleshy: species 8 or so in S. Afr., sometimes mentioned as half-hardy or as greenhouse subjects, but apparently not in the trade. Stemless perennial herbs, with large ternately decompound rigid radical lvs., no involucre, numerous 1-seeded carpels which become thick and juicy at maturity, and greenish or yellowish fls. on branching cymose or umbellate scapes. *K. vesicatòria*, Sims, with lvs. 1 ft. or more across, green fls. and blackish purple berries: lf.-segms. nearly entire or only serrulate: ovaries as long as the subulate style. B.M. 775. B.R. 936. *K. rígida*, Salisb., with lvs. rather smaller, segms. sharply serrate, and ovaries shorter than the subulate style: variable. H.F. II. 7:72.

L. H. B.

KOA. A species of Acacia (*A. koa*, page 186), from the wood of which the Hawaiians make their beautiful highly polished "calabashes."

KÒCHIA (after W. D. J. Koch, 1771–1849, professor of botany at Erlangen; wrote a flora of Germany and Switzerland). *Chenopodiàceæ.* Summer Cypress. Mock Cypress. This includes two hardy annuals, called the "mock cypress" or "summer cypress," grown for the compact habit and the herbage which is green in summer and turns red in autumn.

2041. Kochia trichophylla; often grows in a more ovoid form.

Kochia is a polymorphous genus of herbs which are often woody at the base: lvs. often minute and narrow, alternate, more or less silky, rarely glabrous: fls. small or minute, sessile, solitary or clustered in the axils of the lvs.; calyx enlarging into a flask-shaped body, which incloses the fr.; perianth orbicular; lobes 5, incurved and bearing horizontal wings on the back or on the tube which are membranous or scarious, distinct or confluent; stamens 5; filaments short or long and compressed; stigmas 2, rarely 3.—Species 30–40, of which one is native in the W. U. S. and the others in the Old World and Austral.

The seed may be sown indoors in April, and the plants set out in May, or the seeds may be sown in the open ground about May 1. The plants should stand about 2 to 3 feet apart.

scopària, Schrad. Belvedere. Annual, erect, 3–5 ft., much-branched, more or less pyramidal: branches striate, slender, and close to the main st.: lvs. linear-lanceolate, 2–3 in. long, 2–4 lines wide: fls. inconspicuous, green, in elongated clusters; perianth in fr. provided with very short, triangular, pointed appendages. Cent. Eu.—A plant sometimes grown in gardens for its fastigiate or pyramidal form; used sometimes for brooms. Probably not now grown to any extent in American gardens.

trichophýlla, Stapf. Fig. 2041. The common summer cypress of gardens, although frequently grown under the name of *K. scoparia*, but differing in its ovoid, conical or nearly globular rather than narrow and fastigiate form, by its purple-red color in autumn, and other characters: annual, very much branching, 3–5 ft., making a very compact ovoid object, remarkable for the natural regularity in different plants: lvs. very abundant, alternate, straight, long and linear (2–3½ in. long), sharp-pointed, bright green, puberulent and with long white hairs on the margins near the base: infl. in few-fld. glomerules; fls. polygamous, those on the lateral branches most numerous and female, those at the summit of the principal branches perfect: foliage delicate green, becoming deep red-bronze in autumn. China, probably. R.H. 1907, p. 119. J.H. III. 66:495.—Very useful when formal regular effects are desired, and for its pronounced color in autumn, keeping its shape when most other garden vegetation is destroyed by frost. It is of the easiest cult. This species has been recognized and has come into prominence within the past ten or twelve years.

L. H. B.

KOELÈRIA (G. L. Koeler, professor at Mainz, an early writer on grasses). *Gramineæ.* Tufted perennials, with slender sts.: spikelets 2–4-fld. in dense spike-like panicles.—Species about 12, in temperate regions of both hemispheres; of little horticultural value.

cristàta, Pers. Culms 1–1½ ft., puberulent below the panicles: lvs. fine, mostly basal. Dept. Agric., Div. Agrost. 20:136. Prairies, N. Amer.—Sometimes cult. for lawn decoration in open dry ground.

A. S. Hitchcock.

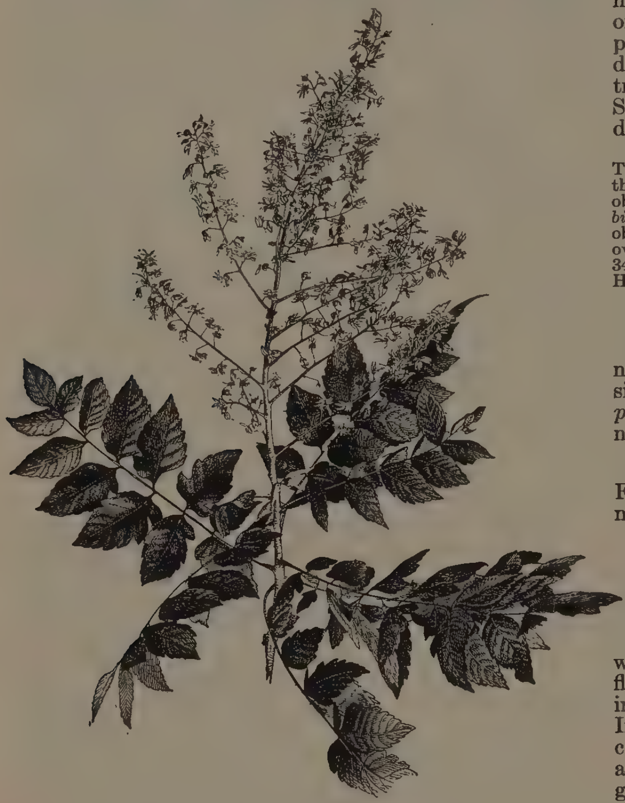
KOÈLLIA: *Pycnanthemum.*

KOELLIKÈRIA (Professor Koelliker, German botanist). *Gesneriàceæ.* One species, a small herbaceous warmhouse plant, **K. argyrostígma,** Regel, Cent. Amer. to Peru, offered abroad: in the way of achimenes, but fls. smaller in leafless racemes, the corolla-limb distinctly 2-lipped: rhizomatous or the root, creeping: lvs. opposite, soft-pubescent, elliptical and nearly or quite obtuse, velvety green and marked with white dots: fls. white or cream-color, red-spotted, in racemes standing 12 in. high; calyx-tube obovoid, the lobes 5 and narrow; corolla-tube short, broad and decurved; upper lip 2-parted and nearly erect; lower lip larger, 3-parted, spreading; stamens attached in base of corolla, somewhat exserted; style filiform, the stigma becoming 2-lobed: caps. 2-valved. B.M. 4175 (as *Achimenes argyrostigma*).—Requires treatment probably of achimenes; prop. by division.

L. H. B.

KOELREUTÈRIA (Joseph G. Koelreuter, 1733–1806, professor of natural history at Karlsruhe). *Sapindàceæ.* Ornamental trees, grown for their large panicles of yellow flowers and the handsome compound foliage.

Deciduous: winter-buds small, with 2 outer scales: lvs. alternate, petioled, estipulate, pinnate or bipinnate, with serrate lfts.: fls. in large terminal panicles, yellow, symmetrical; calyx deeply divided into 5 unequal lobes; petals 4, turned upward, lanceolate, clawed, the blade cordate at the base with 2 upturned appendages; disk crenate at the upper margins; stamens 8, sometimes less, with long filaments; ovary superior, 3-celled, style 3-fid at the apex, shorter than stamens: fr. a bladdery, loculicid caps., with papery walls; seeds usually 1 in each cell, roundish, black.—Five species in China and Japan.



2042. Koelreuteria paniculata. (×⅙)

The koelreuterias are medium-sized rather sparingly branched round-headed trees with light green pinnately divided leaves and small yellow flowers in large terminal panicles appearing in summer and followed by conspicuous bladder-like pods. *K. paniculata* is hardy as far north as Massachusetts, though occasionally killed back in severe winters; as a rule it is a short-lived tree. The other species are more tender. They are not particular as to the soil and prefer sunny positions. Propagation is by seeds, which are usually freely produced and sown in autumn or stratified, also by root-cuttings.

paniculàta, Laxm. (*Sapíndus chinénsis*, Linn.). Figs. 2042–2044. Tree, to 30 ft.: lvs. pinnate or sometimes bipinnate, to 14 in. long; lfts. 7–15, ovate to oblong-ovate, coarsely and irregularly crenate-serrate, at the base often incisely lobed, glabrous above, pubescent on the veins below or nearly glabrous, 1–3½ in. long: fls. yellow, ½in. long, in broad panicles to 18 in. long; filaments hairy: caps. ovate-oblong, gradually narrowed into the pointed apex, 1½–2 in. long. July, Aug.; fr. in Sept. China, Korea, Japan. I.T. 4:147. G.C. III. 2:561. B.R. 330. Gng. 2:353; 8:219. Gn. 32, p. 378. J.H.S. 27, p. 875. G.W. 5, p. 81; 9, p. 9; 13, p. 529.—It is often cult. in the Cent. W., Kans., Mo., and southward, as an ornamental tree, as it stands drought and hot winds well. It is there popularly known as "pride of India" or "China tree," but the first name belongs properly to *Melia Azedarach* and the second to Sapindus; it is also sometimes called "varnish tree," but the true varnish tree is *Rhus verniciflua.*—*K. japónica*, Sieb., is scarcely different; it is said to differ in its more deeply serrate lvs. and smaller fr.

K. apiculàta, Rehd. & Wilson. Closely allied to K. paniculata. Tree, to 35 ft.: lvs. bipinnate, the pinnæ pinnatifid or pinnate at the base, incisely lobed and serrate toward the apex: fr. ovate-oblong, rounded at the apex and apiculate. Cent. China.—*K. bipinnàta*, Franch. Tree, to 60 ft.: lvs. bipinnate with ovate to oblong nearly equally serrate lfts. 1½–4 in. long: fr. globose-ovoid, rounded at the apex. W. China. R.H. 1888, p. 393. Gn. 34, p. 305.—*K. Hénryi*, Dümmer, from Formosa and *K. mìnor*, Hemsl., from S. E. China, are not in cult.

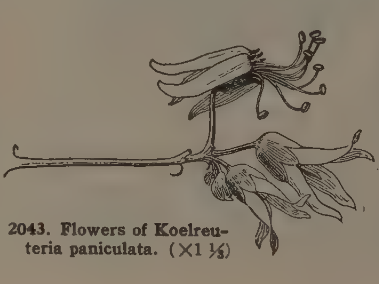
ALFRED REHDER.

KŒNIGA: *Koniga.*

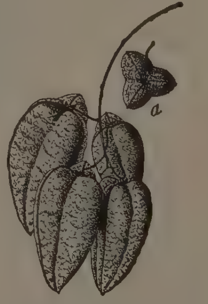
KOHLÈRIA (named for J. M. Kohler, teacher of natural history, Zurich). *Isoloma*, which see for discussion. *K. bogoténse*, Fritsch=*I. bogotense*, Nichols. *K. pícta*, Hanst.=*I. picta*, Planch. (*Gesneria picta*, Hook., not *Achimines picta*, Benth.).

KOHLRABI (*Brassica oleracea* var. *Caulo-Rapa*). Fig. 2045. As the Latin name indicates, this plant is a member of the cabbage group. This group is interesting from a horticultural standpoint because of the great variety in the parts developed to a condition suitable for human food. The kohlrabi is one of the most peculiar of the lot. It is like a turnip produced on a cabbage root, if that were possible. The flesh of the thickened stem resembles that of a turnip, but when well grown it is more delicate, both in texture and flavor. This interesting plant is deserving of a place in every home-garden as well as in the market-garden. In quality it is superior to all other members of the cabbage group save cauliflower. Kohlrabi is naturally a cool-weather plant. To have it at its best it should be grown during the cool days of either spring or autumn and gathered while still young and tender. The soil for kohlrabi should be a rich loam, well drained so as to be available for early planting. Plants may be started in a hotbed and transplanted to the open the same as early cabbage, or the seed may be sown in the open as soon as the season is far enough advanced to sow radish or cabbage seed safely. The rows should be from 15 to 30 inches apart and the young plants planted or thinned to stand 6 to 8 inches apart in the row. The cultivation that would be given early beets will suffice for the plant. The early, quick-maturing sorts should be chosen for table use. The plants should be harvested as soon as the edible portion can be induced to develop to the size of a baseball. If conditions are such as to retard or delay growth, the product is apt to be tough and strong. Quick growth means quality in this plant.

To prepare kohlrabi for market, cut the stem just above the



2043. Flowers of Koelreuteria paniculata. (×1⅙)



2044. Pods of Koelreuteria paniculata. *a*, end view. (×⅙) surface of the ground and tie three to five plants together by their leaves to form a bunch. To prepare it for the table it should be peeled and cut into dice about ½inch square and cooked the same as cauliflower. Vilmorin says that some of the large, coarse varieties are grown in Europe for stock feed. It is doubtful whether it will ever find favor in this country for this purpose for the reason that in most localities turnips, cabbage, or marrow kale will outyield it.

L. C. Corbett.

KOLKWÍTZIA (after Richard Kolkwitz, professor of botany, Berlin). *Caprifoliàceæ.* A shrub allied to Abelia, but differing in the fls. being arranged in pairs at unequal height, one above the other, in the sepals not enlarging after flowering and in the numerous ovules. Only 1 species in Cent. China, recently intro.; it has proved hardy at the Arnold Arboretum, but has not yet flowered. Prop. is by greenwood cuttings in late summer. **K. amábilis,** Graebn. Small deciduous shrub with slender, hairy branches: lvs. ovate, acute or acuminate, rounded at the base, denticulate or nearly entire, sparingly hairy above, more densely hairy below, 1–1¾ in. long: fls. in axillary slender-peduncled pairs, forming short panicles at the end of short branchlets; sepals linear; corolla tubular-campanulate, white, flushed with pink, puberulous, ½in. long; stamens 4, included: fr. a usually 1-seeded ribbed achene, crowned by the persistent stipitate calyx, in pairs. H.I. 30:2937. B.M. 8563.

Alfred Rehder.

KÒNIGA (Charles Konig, of the British Museum early in last century). Sometimes written *Kœniga. Cruciferæ.* A genus established in 1826 by Robert Brown, but now included in Alyssum. Trade-lists still contain *Koniga maritima,* R. Br., which is *Alyssum maritimum;* and *K. variegata* of lists is the variegated form of *A. maritimum. K. spinosa,* Spach =*Alyssum spinosum.*

KÓPSIA (Jan Kops, Dutch botanist, 1765–1849). *Apocynàceæ.* A few trees or shrubs (upward of a dozen species), somewhat allied to oleander, grown in warmhouses and also offered (species not given) in S. Fla. Lvs. opposite, very short-petioled: fls. white or pink, in terminal cymes; calyx 5-parted, the segms. with glandular tips; corolla salverform with a very slender tube and a hairy throat; stamens inserted near the top of the tube, not protruding; disk of 2 glands: fr. 2 carpels; 1-celled, coriaceous or fleshy. India and Malaysia to the Philippines. *K. fruticòsa,* A. DC. Large evergreen shrub, with lvs. 4–8 in. long, elliptic or elliptic-lanceolate: fls. pink, the tube 1½ in. long and limb 1–2 in. across. *K. ornàta,* Hort., shrub from Malaya, with large oblong-lanceolate glossy lvs., and white red-centered salverform fls. in corymbose panicles; apparently not botanically described under this name.

L. H. B.

KOROLKÒWIA: *Fritillaria. K. Sewerzowi,* Regel and *K. discolor,* Hort.=*F. Sewerzowi.*

KORTHÁLSIA (Peter W. Korthals, a German botanist). *Palmàceæ,* tribe *Lepidocàryeæ.* Feather-leaved palms from farther India to Borneo and New Guinea, little grown in warmhouses. Climbing and usually spiny plants with pinnatisect lvs., the lfts. mostly more or less cuneate or trapezoid and erose: fls. perfect, crowded in cylindric and catkin-like spikes; sepals orbicular or oblong, and petals ovate or lanceolate; stamens and staminodia 6 or more: fr. 1-seeded, nearly globular or ovoid: spadix axillary and loosely branched, pendulous, in sheathing tubular presistent spathes: some of the ligules of the petiole-sheath harbor ants.—About 20 species, imperfectly understood. One species is offered abroad. **K. robústa,** Blume (*K. Jùnghuhnii,* Miq.), from Java. Petiole 1 ft. long, not armed; lfts. 7–9, rhomboidal, more or less attenuated below into a stalk-like base, sharp-pointed at apex, 8–16 in. long; rachis backwardly or retrorsely hooked or armed; end of lf. terminating in a hook-like process. Java.

L. H. B.

KOSTELÉTZKYA (named for V. F. Kosteletzky, professor of medicinal botany at Prague, and author of several books). *Malvàceæ.* Perennial herbs or shrubs closely related to Hibiscus, 6 species of which are found in Amer., 1 in. Abyssinia and 1 from W. and Cent. Italy through S. Russia to Persia. Lvs. sagittate, lobed: fls. solitary or clustered in the axils of the lvs., often in terminal panicles or racemes, pink, purple or white; bractlets 7–10, often very small or obsolete; staminal column entire or 5-toothed; ovary 5-celled with 1 ovule in each cell: caps. depressed, dehiscing loculicidally along the 5 projecting angles. **K. pentacárpa,** Ledeb., is the only European species and has been described in horticultural literature abroad. An erect plant, about 3 ft. high: lvs. cordate, toothed: fls. purple-red, rather large, borne singly on peduncles a little shorter than the lvs. **K. virgínica,** Presl. Foliage pubescent, often scabrous: sts. 1–4 ft. high, branching: panicles leafy; calyx canescent; petals pink or purple: caps. hirsute at maturity. Marshes along the coast, N. Y. to Fla. and La.

2045. Kohlrabi.

KRAMÈRIA (John George Henry Kramer, of Hungary in the early part of the 18th century). *Leguminòsæ;* by some referred to *Polygalàceæ.* Woody plants, or perennial herbs, of minor horticultural value, sometimes grown in the warmhouse, from Trop. Amer., upward of a dozen species. Silky-tomentose: lvs. alternate, small, entire or of 3 lfts.: racemes terminal, carrying red or purplish fls.; sepals 4 or 5, about equal; petals 5, very unequal in sets of 3 and 2, the former long-clawed and connate or rarely free, the 2 orbicular and very much shorter; stamens 4, connate part way, the anthers opening by a pore: fr. 1-seeded, coriaceous and indehiscent. *K. triándra,* Ruiz & Pav., of Peru, is probably the most important species horticulturally: small shrub: lvs. alternate or scattered, close together, elliptic or obovate, apiculate, hairy: fls. bright scarlet. This and other species supply the rhatany root of apothecaries.

L. H. B.

KRAÙSSIA: *Tricalysia.*

KRÍGIA (David Krig or Krieg, an early collector in Maryland and Delaware). Syn. *Adopògon,* Neck. *Compósitæ.* Hardy herbaceous plants, annual and perennial, yellow-flowered and sometimes called "dwarf dandelions."

Scapose or leafy-stemmed herbs with heads about 1 in. across, usually yellow, and 15–20 pappus bristles. They differ from the common dandelion in having a pappus composed of both chaff and bristles, instead of bristles alone.—Five species natives of the Atlantic and Gulf states westward, of which three perennial species are cult. by dealers in native plants. Unlike the common dandelion these plants do not become weedy. In the southern states there are two annual species, *K. occidentalis*, Nutt. (*Cymbia occidentalis*, Stand.), and *K. virginica*, Willd. (*K. caroliniana*, Nutt.).

A. *St. a leafless scape, bearing 1 head.*

B. *Plant a tuberous perennial.*

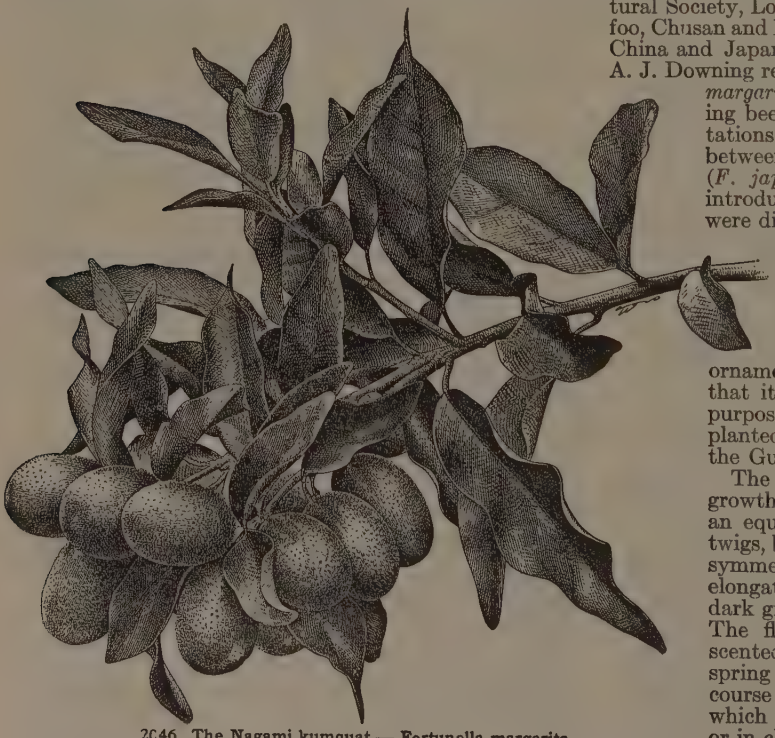
Dandèlion, Nutt. Height 6–18 in., glabrous and bluish green: lvs. lanceolate or almost linear, varying from minutely toothed to pinnatifid: head about 1 in. diam., solitary, the rays yellow. April–June. Moist ground, Md. to Fla. and Texas.—The only kind that has tubers.

BB. *Plant has no tubers, but perennial.*

montàna, Nutt. (*K. Dandèlion* var. *montàna*, Chapm.). Height 9–12 in.: lvs. oblong to linear, varying from entire to pinnatifid: head smaller than in *K. Dandelion*. Crevices of rocks, Alleghenies, N. C. and S. C. and Ga.—Harlan P. Kelsey says that this is an admirable rock-plant, thriving in any soil or situation, and blooming profusely from March to June or July. Prop. by seed or division.

AA. *St. 1–3-lvd., branched above, bearing 2–6 heads.*

amplexicaùlis, Nutt. (*Cýnthia virgínica*, Willd.). Perennial, the st. 1-lvd. and 12–24 in. in height: lvs. oblong or oval, obtuse, entire or repand and denticulate, or the root-lvs. somewhat lyrate; st.-lvs. partly clasping: heads about 2 in. diam., the rays showy, orange-yellow. May–Oct. Moist banks, Ont. to Ga., west to Manitoba.
N. TAYLOR.†



2046. The Nagami kumquat.— Fortunella margarita.

KRYNÍTZKIA (Prof. J. Krynitzki, of Cracow). *Boragináceæ*. Annual and some perennial herbs, with small flowers nearly always white, two of which have been listed for wild-gardens and borders.

Closely allied to Eritrichium, with which the genus has been united; by other writers the genus is broken up in Allocarya, Cryptanthe and Oreocarya. As defined by Gray, the characters are founded mostly on technical features of the nutlet. The species are mostly natives of the W. U. S., and of small promise horticulturally, being usually coarse herbs.

glomeràta, Gray (*Eritríchium glomeràtum*, DC.). Biennial, coarse, grayish prickly-hirsute, 1–3 ft. high: lvs. spatulate or linear-spatulate: fls. white, thyrsoid-glomerate. Plains, along eastern base of Rocky Mts. and to Wash.

barbígera, Gray (*Eritríchium barbígerum*, Gray). Hispid and hirsute, 9–12 in. high: lvs. linear: fls. white, in solitary or panicled, elongating spikes. S. Calif., Ariz., Nev. to Ore.
L. H. B.

KÙHNIA (Dr. Adam Kuhn, an early botanist of Philadelphia). *Compósitæ*. American herbs, closely allied to Eupatorium, seldom planted in the wild garden or border. Perennials, with mostly alternate resinous-dotted lvs., and small whitish or purplish heads in late summer and autumn. From Eupatorium, Kuhnia differs in having 10-angled or -costate achenes rather than 5-costate. Species perhaps 4 or 5, Atlantic U. S. to Texas and Mex. *E. eupatorioìdes*, Linn., is the species most likely to appear in cult. grounds: 2–3 ft., erect: lvs. ovate-lanceolate to oblong-lanceolate or linear, the uppermost usually entire but others usually few-toothed and sometimes short-petioled: heads of white fls. cymose-clustered. Dry places, N. J. to Dak. and S.; very variable.
L. H. B.

KUMQUAT or KINKAN. Fig. 2046. A group of dwarf evergreen citrous fruits of the genus Fortunella but formerly referred to Citrus, introduced into England by Robert Fortune, collector for the Royal Horticultural Society, London, from the provinces of Foo-chow-foo, Chusan and Ningpo, China, May 6, 1846. In both China and Japan the kumquat is grown extensively. A. J. Downing reports the variety Nagami (*Fortunella margarita*) as being in America in 1850, having been brought from England, and importations from Japan by Florida nurserymen between 1885 and 1890 included the Marumi (*F. japonica*) variety. Shortly after their introduction into America, both varieties were distributed throughout the Gulf coast and California citrous regions and soon attracted attention for their ornamental value. Later the variety Neiwa (*F. crassifolia*) was introduced but is not yet commonly known. While the kumquat was first regarded as an ornamental in America, it was soon realized that its fruit is valuable for many culinary purposes. In consequence it has been largely planted in many sections, particularly along the Gulf of Mexico.

The kumquats are distinctly shrubby in growth, reaching a height of 10 to 15 feet and an equal distance across the branches. The twigs, branches and leaves make a very dense symmetrical head. The leaves are narrow, elongated, pointed or rounded at the apex, dark green. Thorns are absent or very small. The flowers are small, white and sweet-scented. The first blooms produced in early spring are usually without pistils and of course no fruit results. Later the flowers from which the fruit is produced are borne singly or in clusters of three or four on shoots that arise from the first growth in spring. There may be one or two successive crops of bloom and settings of fruit. The ripening of the fruit is therefore usually prolonged over a period of several weeks or even months. The fruit is small, either oval or round, orange in color, and borne freely.

The kumquats are among the most hardy of the citrous fruits. In dormant condition they have withstood temperatures as low as 15° F. in the latitude of north Florida without injury, and they have been fruited in the open ground as far north as Augusta, Georgia.

While the kumquat may be budded on any of the stocks commonly used for other citrous fruits, most of them are grown on *Poncirus* (or *Citrus*) *trifoliata*, rough lemon, and sweet orange stocks. When soil and moisture conditions are suitable, *Poncirus trifoliata* is given the preference. It is a very hardy stock and well adapted to the kumquat. For pot culture, when both soil and moisture are under control, it is the best stock to use. The ordinary shield method of budding is used, and the young plants, being of shrubby growth do not require any special training such as must be given other citrous trees.

In orchard planting, the kumquats are usually placed 10 by 10 feet up to 15 by 15 feet apart. Sometimes they are grown in hedges, the plants being set 6 feet apart in the rows and the rows 15 feet apart. The same tillage and fertilizing are required as for other citrous fruits. Plant-food must be available in liberal amounts to keep the fruits up to size, and fertilizers should be applied in goodly amounts in late winter to produce a strong growth in the first spring shoots.

In the matter of pruning, kumquats are very much benefited by rather severe cutting back of the twigs of the previous season's growth in the winter months. Since the fruit is usually gathered with twigs attached, the necessary pruning is given when the crop is harvested, but if the crop is light, additional pruning will be necessary and should be directed toward thinning out the shoots as well as cutting them back. Liberal pruning well in advance of the starting of growth increases both the size and quantity of fruit.

Varieties.

Up to this time three varieties have been introduced into America, as already noted. A fourth variety, Omi, is listed in Japanese catalogues, and there are doubtless still other forms in China and Japan.

Nagami.—Oblong fruit 1¼ to 1¾ inches long, deep orange in color; juice acid; rind sweet, spicy; seeds two to five; season October and through the winter. Usually begins to ripen two or three weeks later than Marumi.

Neiwa.—Fruit 1¼ to 1¾ inches in diameter, round, orange-yellow; juice subacid; rind sweet; season earlier than Nagami; prolific. A recent introduction.

Marumi.—Round; fruit 1 to 1¼ inches in diameter, round, irregular in size; deep orange in color; juice acid; rind sweet and spicy; seeds one to three; season October and through the winter. The earliest variety to ripen.

Nagami is usually considered the most desirable variety, as it is more robust in growth and produces fruit of uniform size. Marumi is very prone to produce fruit that is small and very irregular in size. Nagami is thornless, while Marumi has very short, sharp, slender thorns. As a pot-plant, Marumi is valuable because of its very compact symmetrical growth.

Uses.

Well-grown kumquat plants make handsome ornamentals,—the combination of dark green foliage and small golden fruit being very pleasing. They may be used for hedges, planted singly or in groups.

Large quantities of fruit are shipped for the holiday trade. In gathering the fruit, it is clipped from the plants with leaves and twigs attached and packed in strawberry baskets. There is also a good demand for large sprays of fruit and leaves for decorative purposes.

When eaten raw, well-ripened kumquats have a very agreeable combination of flavors. The outer rind is spicy, the white inner rind is sweet and granular, while the juice is acid.

2047. The round kumquat.—Fortunella japonica. (×½)

The fruit is coming into very general use for the making of marmalade, jelly, preserved and crystallized fruit. Marmalade made from kumquats is esteemed by many above the product made from other citrous fruits.

H. Harold Hume.

KÚNZEA (Gustav Kunze, 1793–1851, German botanist). *Myrtàceæ.* Australian shrubs, sometimes grown in cool or temperate houses: often heath-like, the small entire lvs. mostly alternate: fls. small with extending stamens, in the upper axils or in terminal heads or in a spike below the end of the branch; calyx with 5 small lobes; petals 5, spreading, small; stamens many, free or in series, the filaments filiform; ovary 2–5-celled, 2 to many ovules in each cell. The species are 15–20, allied to Callistemon, Leptospermum, and formerly included in Metrosideros. The cult. requirements of Callistemon (p. 630) will probably suit them. *K. pomífera*, F. Muell., has been mentioned as a fruit-plant (G.C. III. 5:201; copied in A.G. 1889: 127), Mueller saying that it is one of the few really valuable fruit-plants indigenous at the south coast of Austral. "The fruits are of a peculiar acidulous aromatic taste, and very extensively collected by people settled on the coast for the purpose of jam-making." It is described by Bentham as a rigid prostrate shrub: lvs. ovate, varying from nearly orbicular and almost cordate to narrow and acute-based, mostly less than

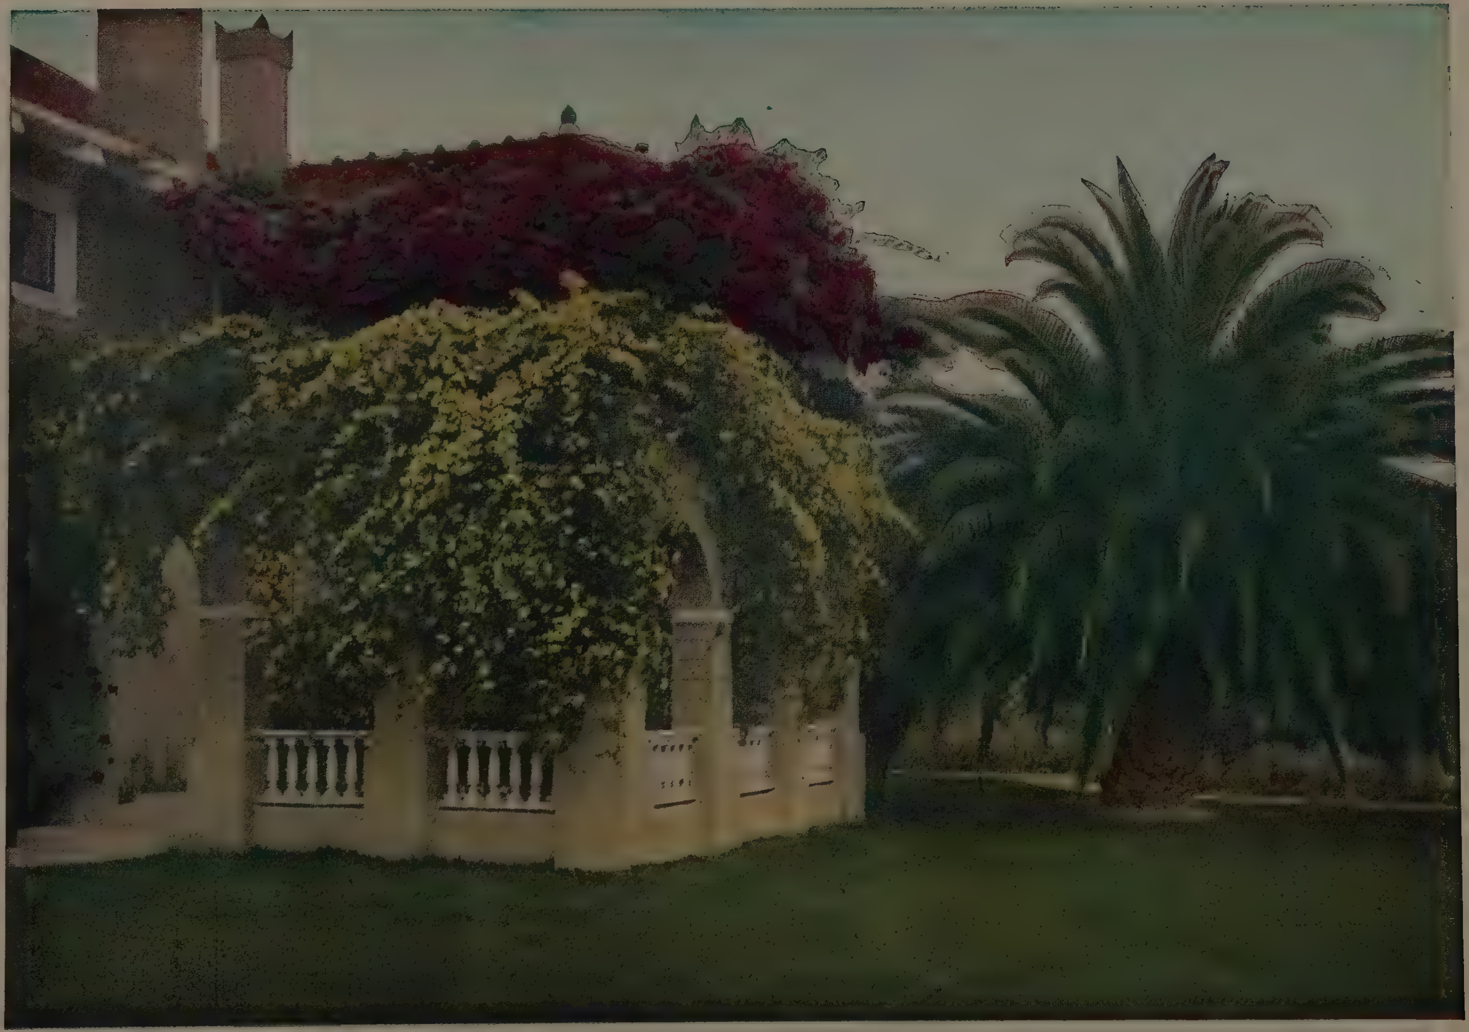
⅓in. long: fls. white or yellowish, sessile and not numerous but yet forming dense terminal heads becoming lateral by elongation of the branch; stamens numerous, 3 or 4 times as long as the small petals: berry blue, ⅓in. or less diam., crowned by the calyx-lobes. Victoria and S. Austral. L. H. B.

KÝDIA (Col. Robert Kyd, founder of the Calcutta Botanic Garden, died 1794). *Malvàceæ.* Oriental trees, one of which has been cultivated in southern Florida and southern California.

Plants with stellate pubescence: lvs. entire or lobed, palmi-nerved: fls. polygamous, in panicles, white or pink, ornamental; sepals 5, joined at the base, subtended by 4–6 leafy bracts which enlarge in fr.; petals 5, exceeding the calyx and joined to the stamen-tube; staminal tube divided about the middle into 5 divisions, each bearing 3 anthers, which are imperfect in the pistillate fls.: fr. a 3-valved caps.—Two or three species in India.

calycìna, Roxbg. Tree, attaining 25 ft.: lvs. 4–5 in. long, 3 in. wide, rounded, cordate, palmately 7-nerved, more or less lobed, midlobe longest, close-felted beneath: infl. much-branched, many-fld.; fls. white or pink, with oblong-spatulate bracts beneath. Trop. India.—Indicated as a stove evergreen abroad. It is doubtful whether the plant is still cult. to any extent. L. H. B.

KYLLÍNGA (Peder Kylling, Danish botanist, died 1696). *Cyperàceæ.* Annual and perennial herbs, of little value horticulturally although one species is sometimes mentioned in gardening literature. Grass-like or sedge-like plants of perhaps 30 species in many parts of the world, with very small fls. in spikelets which are aggregated into spikes or heads. *K. monocéphala*, Rottb., is nearly glabrous with a creeping rhizome: lvs. drooping or arched, in a graceful tuft: culms. 3-angled: spikes terminal, ovoid or cone-shaped, silky, white, the subtending lvs. 3 and spreading-deflexed. India and other warm regions of the Old World, where it is common. This species is recommended for greenhouse work, where, in 4-in. pots, it makes decorative specimens 1 ft. high, requiring a warm greenhouse temperature. G. 2:298; 25:173. Apparently not offered in this country. L. H. B.



LXI. Landscape in southern California.—Bougainvillea above; Banksian rose in yellow; Phœnix canariensis.

L

LABELS. There are two reasons for using labels,—to display the names of plants in public plantations for the information of visitors, and to enable the gardener to preserve the name of the plant for his own use. In the former use, the label should be prominent, as permanent as possible, and attractive or at least not obnoxious in itself. In the latter case, the label may be only a tag or tally, and it is often of temporary use.

The characters demanded in a good plant-label in general are legibility, convenience, durability and a reasonable cheapness. The purposes for which labels are needed by the horticulturist may be grouped as follows: (1) For pots, boxes, frames and benches; (2) for stock in storage or transit; (3) for rows, plots or beds in garden, nursery, orchard; (4) for individual trees, shrubs and plants.

Of the materials that may be used for gardeners' labels, wood holds the first place, and the soft, easily worked nature of white pine makes this the favorite species, although other more durable woods, such as cedar, spruce, cypress and mulberry, are used to some extent. Machine-made ready painted wooden labels of convenient shapes and sizes, from 4 to 12 inches in length (see No. 1, Fig. 2049), are carried in all stocks of gardeners' supplies, and are in common use in all work with plants in pots, boxes and benches, and to some extent in out-of-door gardening, but these should not be trusted where the label is expected to endure for a considerable time. In the storage of grafts and cuttings in pits or cellars, two of these labels should be written and slipped together under the tie, the outer one for immediate reference and the under and protected one for security when the other becomes defaced.

2048. A stamped aluminum label, with raised letters.

Notched or perforated labels (Nos. 2, 3, Fig. 2049), with or without wires, are also prepared for nurserymen's use, those strung with soft copper wire being the best. These are used in the shipping of nearly all trees and shrubs, and here great annoyance would be saved if all names were written distinctly and with a heavy impression. If such labels are used on stock after planting, the grower should use great care that stems and branches are not choked by the wire. The printing of any desired names may be procured on order, effecting a great saving of time and a gain in distinctness.

For marking rows, plots, and beds, stakes should be used large enough readily to attract attention and not be broken over or moved in cultivation. A very serviceable stake for nurseries, trial grounds and gardens is made by cutting 2-inch pine or cypress plank 2½ inches wide and 2 feet long, pointing and giving two good coats of paint. Inscriptions may be stenciled on these as suggested in No. 4, Fig. 2049, written with a heavy pencil, or better, where names, dates and list or plot numbers are wanted, written on a square of sheet zinc and fastened to the face of the stake with small nails. (No. 5, Fig. 2049). An annual coat of paint obliterates old lettering and preserves the wood.

A common wooden label for borders, groups or specimen plants is shown by No. 6 and a variation by No. 7 (Fig. 2049). The stakes should be of some durable wood, and the whole well painted. A paint of pure lampblack and oil is the most indestructible and letters will stand out like type after the lead paint and the very wood surface have weathered away. An effective contrast is obtained by painting the face of the label black and placing the lettering in white.

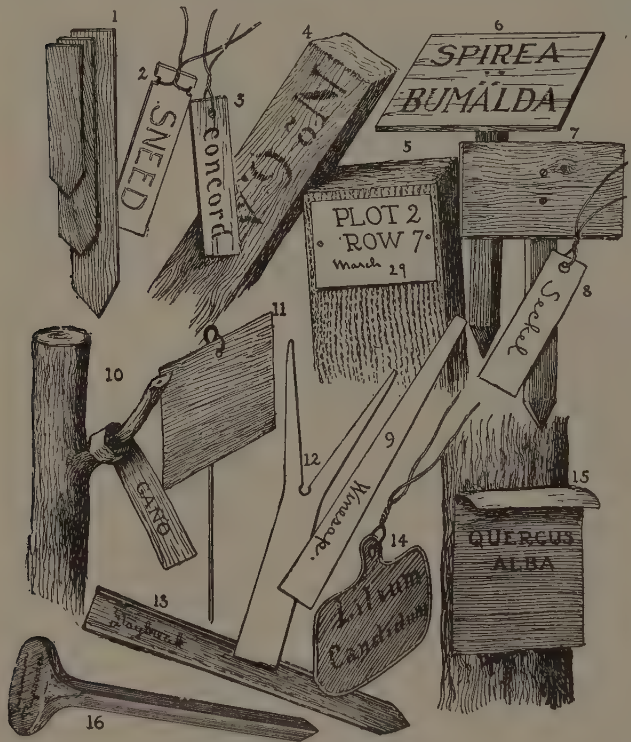
For display labels on trees and posts in parks and experiment stations, sheet aluminum is now used, with the name stamped in raised letters by a machine or by hand dies (Fig. 2048). Such labels are durable, are not injured by sprays, keep clean, and are cheap in first cost if the number to be made is enough to warrant the purchase of an equipment. We must now provide for labels that withstand spraying compounds.

Of the sheet metals, zinc has heretofore proved superior to other materials. It may be stamped with steel letter dies or written upon with a common lead pencil, but more commonly a chemical ink is used. The common formula for this in horticultural books is substantially that prepared by the French chemist, Brainnot, in 1837, and is as follows: Two parts by weight of verdigris (acetate of copper), two of sal ammoniac (ammonium chloride), one part of lampblack and thirty parts of soft water. The chemicals should be incorporated with a little of the water, and the remainder added. Keep in a glass bottle tightly corked and shake frequently while using, as the lampblack tends to separate. The zinc, cut in the desired forms, should be prepared by scouring slightly with emery dust or fine sandpaper. The ink may be applied with a quill or coarse steel pen, but a fresh one will be needed with each batch of labels. Inks of an aqueous solution of chloride of copper or of chloride of mercury are also recommended for writing on zinc, which should first be cleaned with a weak solution of muriatic acid. Bichloride of platinum is one of the blackest inks for zinc. A slightly oxidized zinc surface may be written upon with a soft lead pencil, and while the inscription will not be very distinct at first will grow more so with age, and will endure for years.

It is always best to secure a sheet-metal label to the bole or post by both ends if possible; but in many cases a hanging label must be used. A wired zinc label, as shown in No. 8, Fig. 2049, if exposed to the wind will sometimes cut the eye completely out, unless care is taken to twist the wire up tightly. If the end of the label is folded over and the hole punched just beyond the fold, it will not be so likely to pull out. Strips of zinc ⅝ inch wide and 7 inches long (No. 9, Fig. 2049), coiled loosely around a branch, as in No. 10, are a serviceable form of tree-label, but even these should be noticed every year, that they do not become fastened into the fork of a rapidly-growing tree.

For borders or beds of herbaceous perennials, bulbs, and the like, the label shown in No. 11 is excellent and inexpensive. A piece of galvanized wire Nos. 6–8 in size, is cut 1½ to 2 feet long, bent to shape and the written zinc tablet closed in. For a more conspicuous label, the zinc may be given a coat of white lead, then one of black enamel paint, and the letters be traced in white. In some European botanical gardens a zinc tablet stamped with sunken letters brought into relief by paint are used for similar purposes. A zinc label, with two wire legs to prevent it from turning around, is shown in Fig. 2050.

There are many designs of cast or enameled metal or porcelain labels, that have found little use in this country. A label of stamped zinc of English manufacture (shown in No. 16, Fig. 2049) is one of the best garden labels. For labeling specimen tree trunks, a sheet of zinc or copper with a little water-ledge bent at the top, painted, enameled black and lettered in white, is neat and useful. It should be secured with copper tacks, and given occasional attention. (See No. 15.) A series of thin sheet-copper labels, to be written on with a stylus against a soft, yielding surface, as a piece of leather, are shown in Nos. 12, 13, 14. These may be too frail for out-of-door use, but are very good for conservatory plants, although the inscription needs rather close examination. Of copper labels, the temper should be taken out and the metal folded on edges. A neat label for conservatory use is made of white sheet-celluloid with a mat surface, as pencil marks show very plainly on it.



2049. Various types of labels.

Several kinds of tree-labels are shown in Fig. 2052, as follows: Nos. 1, 2, German labels, made of glazed earthenware, with the name colored blue and sunken. Strong copper wire, coiled, to allow of the growth of the limb, holds the label to the tree. No. 3, Cornell label is made of wood. No. 4, double wooden label, consisting of two common wooden labels fastened together. The name is written upon the outside of the double label, as in any other label, but it is also written on the inside to insure permanence. When the outside writing is worn off the label is opened and the inside is still bright. The label is fastened to the tree by a tack or small nail, as shown in the cut at the right. The label is seen opened in the cut at the left. Nos. 5, 6, zinc labels, used at the New York State Experiment Station, Geneva. The wire is driven into the tree, and the name is written or printed on the zinc with black paint. No. 7, common handmade wooden tag, taken from an old tree in the test orchard of the late Charles Downing, Newburgh, New York. No. 8, thin copper label, with the name indented into the metal by the use of a hard-pointed instrument. Some metal labels are apt to tear out at the hole when exposed to winds. No. 9, common painted pine label used by nurserymen, and costing (without the copper wire) about 35 cents a thousand for the common size, which is 3½ inches long. No. 10, Lodeman's label, used somewhat at Cornell, consisting of a tag of sheet lead securely fastened to a coiled brass wire. The wire is secured to the body of the tree by a staple or screw-eye, and it is expected that the wire will become imbedded in the trunk as the tree grows. No. 11, common zinc label or talley. A good vineyard label is shown in Fig. 2051, described by Bailey as follows: The figure is Paddock's vineyard label (designed by W. Paddock, State Experiment Station, Geneva, New York). The label is a strip of heavy zinc secured to a stiff galvanized wire. This wire or shank is provided with a hook at the lower end and a half-hitch near its middle, so that it can be securely adjusted to the wires of the trellis, holding the label well above the foliage.

2050. A metal garden label.

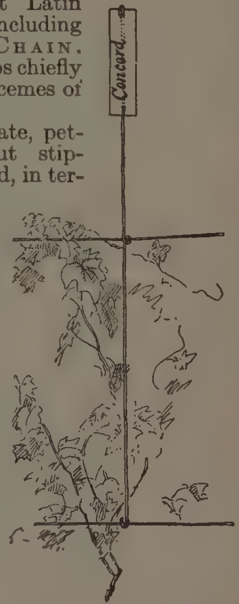
S. C. Mason.
L. H. B.†

LABLAB: *Dolichos.*

LABÚRNUM (ancient Latin name). *Leguminòsæ.* Including *Podocýtisus.* GOLDEN-CHAIN. Ornamental trees or shrubs chiefly grown for their showy racemes of yellow flowers.

Deciduous: lvs. alternate, petioled, 3-foliolate, without stipules: fls. slender-pedicelled, in terminal simple racemes, mostly pendulous; calyx 2-lipped, with obtuse, short lips; corolla papilionaceous, with the petals all distinct; stamens 10, all connate; ovary stalked: fr. a linear pod with several seeds, compressed, tardily dehiscent; seed without appendage at base.—Three species in S. Eu. and W. Asia, often included under Cytisus. All parts of the plants are poisonous, especially the young frs. The hard, tough and close-grained wood is susceptible of a very fine polish, and is manufactured into various small articles.

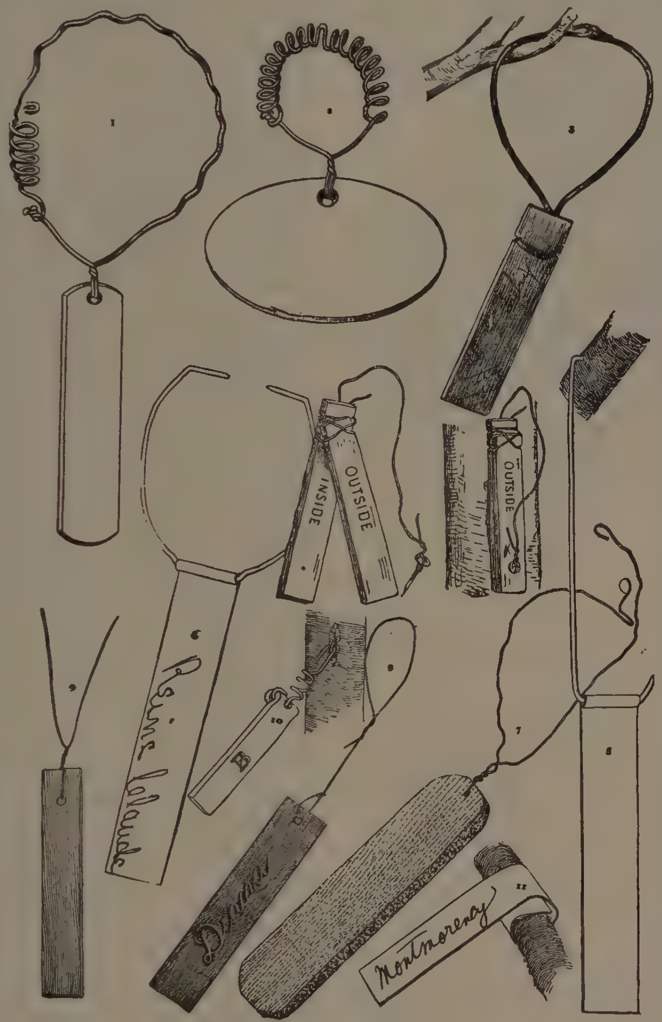
The golden-chains are handsome small trees with dark



2051. Paddock's vineyard label.

green trifoliolate leaves falling late in autumn without change of color, and with drooping racemes of bright yellow flowers in late spring, followed by long narrow pods remaining on the tree a long time. They are adapted for planting on rocky slopes or in borders of shrubberies, where they should be allowed enough space to show to the best advantage their graceful, drooping racemes of golden flowers, which contrast with the dark green foliage. They are hardly ever attacked by insects or fungi.—*Laburnum alpinum* is the hardiest species and perfectly hardy as far north as Massachusetts; *L. anagyroides* is somewhat less hardy, while *L. caramanicum* is tender. They thrive in any kind of well-drained soil, including limestone, and grow as well in partly shaded positions as in sunny ones. Propagated by seeds, sown usually in spring, and also by layers; the varieties are mostly grafted or budded on seedlings of one of the species.

anagyroìdes, Medikus (*L. vulgàre*, Griseb. *Cýtisus Labúrnum*, Linn.). GOLDEN-CHAIN. BEAN-TREE. Fig. 2053. Large shrub or small tree, to 20 ft., with erect or spreading branches: branchlets appressed-pubescent, grayish green: lvs. long-petioled; lfts. elliptic or elliptic-ovate, usually obtuse and mucronulate, glaucous-green and appressed-silky pubescent beneath when young, 1–1¾ in. long: racemes silky-pubescent, 4–8 in. long; fls. about ¾in. long: pod appressed-pubescent, with thick keel, about 2 in. long; seeds black. May, June. S. Eu. Gn. 25, p. 518; 34, p. 30, and 51, p. 302. G.C. III. 36:318. H. W. 3, p. 101.—There are many garden forms. Var. **aùreum**, Rehd. (var. *chrysophýllum*, Schneid.), with yellow foliage. F.S. 21:2242, 2243. F. M. 1875:182. G.Z. 20:129. Var. **bullàtum**, Schneid. (var. *involùtum*, Hort.), with curled lfts. Var. **Carlièri**, Schneid. (*L. vulgàre Carlièri*, Kirchn.). Lvs. smaller: fls. smaller in short upright racemes, often several from one bud. Var. **péndulum**, Rehd., with pendulous branches. Gn. 25, p. 522. G.M. 45:317. Var. **quercifòlium**, Schneid., with sinuately lobed lfts. Gn. 25, p. 520; 34, p. 30. Var. **sessilifòlium**, Schneid., with crowded, sessile lvs. Var. **Alschíngeri**, Schneid. (*L. Alschíngeri*, Koch). Racemes shorter, lower lip of calyx longer than upper lip: lvs. more silky. S. E. Eu. Var. **autumnàle**, Rehd. (*L. vulgàre autumnàle*, Kirchn. *L. vulgàre bífera*, Lavalle. *L. vulgàre semperflòrens*, Nichols.). Blooms a second time in late summer.



2052. Tree labels of many patterns.

alpìnum, Griseb. (*Cýtisus alpìnus*, Mill.). SCOTCH LABURNUM. Shrub or tree, to 30 ft., similar to the former: branchlets glabrous or hirsute when young: lfts. usually elliptic, acute, light green and glabrous beneath or sparingly hirsute, ciliate, 1–1¾ in. long: racemes long and slender, glabrous or sparingly hirsute; fls. smaller: pod thin, with the upper suture winged, glabrous; seed brown. June. Mountains, S. Eu. B.M. 176 (as *Cytisus Laburnum*). Gn. 25, p. 519; 34, p. 30. R.H. 1912, p. 446. G.M. 45:316. G. 36:477. Var. **péndulum**, Koch. With pendulous branches. Gn. 25, p. 522. A var. *aùreum* is advertised.—This species flowers about 2 weeks later than the former, and has much longer and more slender racemes; it also is of more upright and stiffer growth and hardier.

Wátereri, Dipp. (*L. Párksii*, Hort. *C. alpìnus* × C. *vulgàris*, Wittst.). Hybrid of garden origin, but found also wild. Lvs. beneath and racemes sparingly pubescent: racemes long and slender: pod with narrow wing, sparingly appressed-pubescent, few-seeded. G. 24:355. G. M. 45:313.—As hardy as *L. alpinum* and sometimes considered to be a variety of that species.

Ádamii, Kirchn. (*C. Ádamii*, Poir. *C. Labúrnum purpuráscens*, Loud. *Laburnocýtisus Ádamii*, Schneid. *L. vulgàre* × *Cýtisus purpùreus*). Originated at Vitry, near Paris, about 1826. Habit and foliage usually almost like *L. anagyroides*, but fls. dull purplish, rarely yellow; sometimes bearing a few branches with the fls. and lvs. of *Cytisus purpureus*. A very interesting form, but of less ornamental value. B.R. 1965. B.H. 21:16–18. G.C. III. 36:219; 50:162.—One of the so-called graft-hybrids which have recently been termed chimæras, as there is no fusion of cell-contents and nuclei, but only a mixture of tissues.

L. caramánicum, Benth. & Hook. (Podocytisus caramanicus, Boiss.). Erect shrub, to 4 ft., much resembling in foliage and habit the Cytisus sessilifolius, with long and slender terminal upright racemes. July–Sept. Asia Minor. R.H. 1861, p. 410. G.C. III. 48:454. B.M. 7898.—*L. fràgrans*, Griseb., *L. ramentàceum*, Koch, and *L. Wéldeni*, Lavalié.=Petteria ramentacea.

ALFRED REHDER.

LABYRINTHS or mazes are intricate and confusing networks of walks and passages within hedges of evergreen, formerly employed as a garden entertainment and conceit. They are still kept up in some Old World gardens as relics of the past. They were popular in the sixteenth and seventeenth centuries. Fig. 2054 is the plan of an English labyrinth of two centuries ago. It would be vandalism to destroy so fine an example of a style of gardening no longer fashionable, but folly to copy it in a modern garden. Mazes are made of clipped evergreens of various kinds.

2053. Laburnum anagyroides. (×⅓)

LACÆNA (one of the names of Helen, which Lindley states may be applied to this plant on account of its beauty; but he adds it may also be derived from *Lakis*, a cleft, alluding to the divisions of the lip). *Orchidàceæ.* A little-known group of epiphytic orchids inhabiting Central America and Mexico.

Pseudobulbs rather long, ovoid, smooth at first: lvs. large, elliptic-pointed and contracted into a petiole, plicate venose: raceme pendent from the base of the pseudobulbs, loose, bearing up to 10 medium-sized fls.; sepals and petals nearly equal, elliptical, half-spreading; labellum equaling the petals, articulated to the base of the column, clawed, with the lateral lobes incurved, terminal larger, spreading and narrowed at the base to a broad claw; column rather long, winged, hooded at the top; pollinia 2 on a simple stipe.—Only 2 species.

The plants should be grown in baskets or on blocks of wood like stanhopeas: if potted the racemes are likely to bury themselves in the soil. At the end of October, water should be almost entirely withheld for a few weeks. The flower-stalks appear in spring.

bícolor, Lindl. (*Lueddemánnia Sanderiàna*, Kränzl.). Racemes drooping, about 18 in. long, bearing 9 or 10 fls.; fls. greenish yellow, covered externally with short hairs; petals with 3 purple streaks; labellum hairy, spotted with purple. Discovered about 1843 in Guatemala, at an elevation of 7,000 ft. B.R. 30:50. Var. **glabràta,** Lem. Fls. everywhere nearly glabrous, creamy white. Not in the American trade. I.H. 1:33. Var. **álba,** Hort. Fls. yellowish white, without purple markings.

spectábilis, Reichb. f. Fls. about 1 in. diam., whitish, suffused with pink and speckled with purple; sepals concave orbicular; petals smaller, connivent. Costa Rica. Mex. (?). B.M. 6516.—Far more handsome than the former, but not advertised in Amer.

Heinrich Hasselbring.

LACE-BARK: *Lagetta;* also *Gaya* and *Hoheria.*

LACE-LEAF, LATTICE-LEAF· *Aponogeton.*

LACHENÀLIA (Werner de Lachenal, 1736–1800, professor of botany at Basel). Including *Scillópsis. Liliàceæ.* Cape Cowslip. Small Cape bulbs that are easily flowered in a cool greenhouse in early spring or even in winter; some of them are useful also for the window-garden.

Plant comprised of a tunicated bulb, a leafless peduncle or scape bearing a raceme or spike of fls. in shades of red and yellow, sometimes white, and usually 2 lvs. at the base of the scape: perianth tubular, persistent, the 3 outer segms. oblong and slightly swollen near the apex, the 3 inner segms. commonly longer and obtuse-spatulate; stamens 6, attached in the perianth-tube; style long and slender, with capitate stigma: caps. loculicidally 3-valved, with turgid black seeds.—Species about 50, in S. Afr. They have a remarkable range of color, and with good management may be kept in an attractive condition for 2 months or more. There are species with bell-shaped fls. and some in which the fls. are all more or less erect, but the favorite types are the long, cylindrical, pendulous fls. with the brilliant red and yellow colors. But few species are cult., the most popular being *L. tricolor*, particularly its var. *Nelsonii* and some of the recent forms with personal names. *L. pendula* is perhaps second in popularity, the others being known chiefly to bulb fanciers. Lachenalias are very distinct in coloring and general appearance. They usually have 2 lvs. (sometimes 5 in. cult.), rarely 1, and the bulbs are globose, tunicated, and about ½–1 in. thick. An exceptionally strong bulb, under the most favorable conditions sends up 3 or 4 erect fl.-stalks 9 in. high, with as many as 40 fls., each 1–1½ in. long. Under careless treatment the lvs. and fl.-stalks are weaker, and bear perhaps 6–12 fls. Lachenalias are good subjects for hanging-baskets.

It is well to make one job of it, planting freesias and lachenalias together. Six are planted in a 6-inch pot, in good rich loam. They probably do as well without leaf-soil, if the drainage is good. They are stored in a well-protected coldframe until late in November, but might be kept longer, as a pinch of frost will not hurt them. After they are brought into the greenhouse, and make good growth, plenty of water may be given, and, occasionally, liquid manure. A night temperature of 50° F. will be found about right, but they scarcely bear forcing until the flowering scapes show. If forced before the bulbs show, the flowers are often malformed. They last in bloom from six to eight weeks, after which follows the same routine.—After blooming, the plants should be set on a shelf in a light position and watered as carefully as before the blooming season, less water being given as signs of maturity appear; viz., discolored leaves and withered flower-stems. When thoroughly ripened, they are stored in the pots they have grown in and kept quite dry until the month of August. They must be repotted then. If by chance drip should strike the soil, the plants may be found starting into growth. The bulbs multiply rapidly, more than doubling in a season. Fully one-third of the extra bulbs will be serviceable, and still more would make bloom of less decorative value. There are many more—bulblets—which can be sown on the borders of carnation or violet benches, a large number making good-sized bulbs in one season. Seeds of lachenalias germinate readily in a few weeks, and with good treatment many seedlings will bloom before going to rest. In the opinion of the writer, *L. Nelsonii*, is still the most satisfactory kind to grow. (T. D. Hatfield.)

A. *Perianth ventricose, oblique at the base.*

1. **refléxa,** Thunb. (*Cœlánthus complicàtus*, Willd.). Bulb globose, ¾in. or less diam.: lvs. 2, thin, falcate, clasping the base of the st. for 1–2 in.: peduncle and infl. 2–6 in. long; spike usually few-fld., the rachis flexuose; fls. all erect or spreading, yellowish, about 1 in. long; inner segms. slightly longer than the outer and spreading at the very tip; stamens included, but style becoming exserted.—*L. Regeliana* is a hybrid of this and *L. tricolor* var. *aurea.*

AA. *Perianth oblong to cylindrical, not oblique or ventricose.*

B. *Fls.* (*at least the lower ones*) *drooping or pendulous.*

2. **rùbida,** Jacq. Bulb globose, about ½in. thick: peduncle and infl. 6–9 in. long: lvs. usually 2, much-narrowed to base, spotted: raceme 6–20-fld.; outer segms. bright red, tipped green; inner ones yellow below the tip, a little longer than the outer segms.

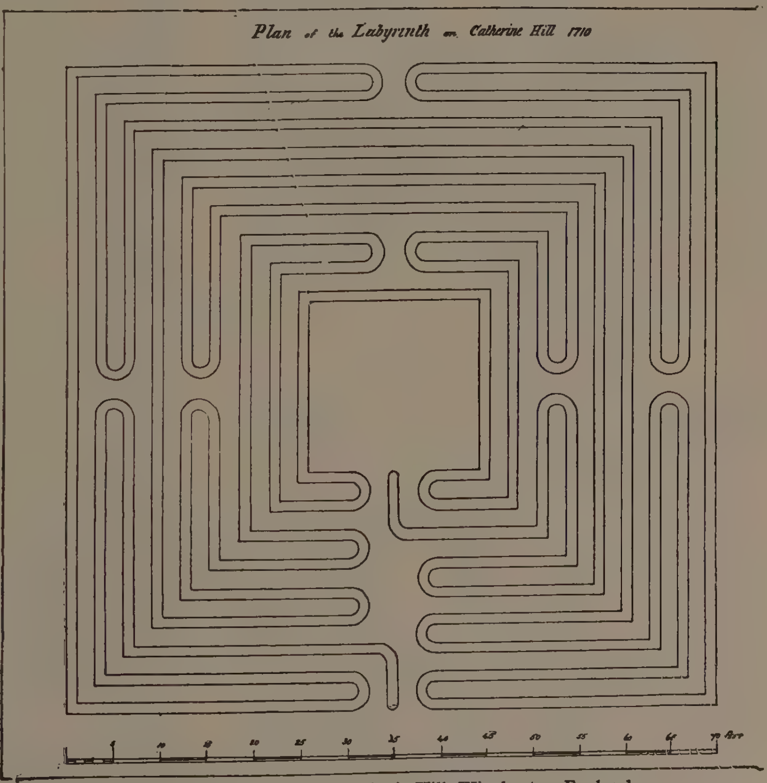
3. **péndula,** Ait. Bulb globose, about 1 in. thick: peduncle and infl. 6–12 in. long, more robust than in Nos. 2 and 4; raceme few- or many-fld., 2–6 in. long, all except the upper fls. more or less nodding; outer segms. linear-oblong, yellow, passing upward into red, not spotted; inner bright red-purple at the tip, little if at all exceeding the outer. B.M. 590. Gn. 18:60; 23, p. 142; 33, p. 249, and 45, p. 355. Gt. 61, p. 218. G.W. 10, p. 329. G. 5:551. F. 1871:265. V. 8:172. Var. **aureliàna,** Hort., has outer segms. red, barely tipped yellow; inner ones tipped green. R.H. 1890:396. G.C. III. 23:195.

4. **trícolor,** Thunb. Bulb globose, to 1 in. diam.: peduncle and infl. to 1 ft.: lvs. usually 2, 6–9 in. long, often spotted: raceme mostly 3–4-fld., sometimes many-fld.; lower fls. nodding; outer segms. yellow, tipped green; inner purplish red at the tip, much exceeding the outer. L.B.C. 8:767. B.M. 82. F. 1871:265. Gn. 18:60; 47, p. 163. G.W. 10:329. Var. **quadrícolor,** Baker (*L. quadrícolor*, Jacq.). Perianth with a red base and greenish yellow middle; outer segms. tipped green; inner ones tipped red-purple. L.B.C. 8:746. Var. **lutèola,** Baker (*L. lutèola*, Jacq.). Perianth lemon-yellow, tinged green toward the tip. B.M. 1020; 1704. L.B.C. 8:734. F.S. 18:1873. Var. **lutèola maculàta,** Hort. (*L. lutèola maculàta*, Hort.), differs from the preceding in having spotted foliage. Var. **Nélsonii,** Baker (*L. Nélsonii*, Hort.). Fig. 2055. Perianth bright yellow, both series of segms. faintly tinged green: probably the lachenalia most grown in this country, bearing freely for a long season long racemes of brilliant fls.: treated much as are hyacinths indoors, being kept cool. Gn. 49, p. 470; 75, p. 143. Gng. 5:262. J.H. III. 30:231; 62:291; 63:136. Gn.W. 16:25; 21:301. G.W. 43:591; 52:724. G.Z. 31:121. G. 19:174. **Var. aùrea,** Hook. (*L. aùrea*, Lindl.). Perianth bright orange-yellow. F. 1871:265. B.M. 5992.—Baker observes that "the varieties are connected by intermediate stages. Several hybrids between *L. pendula* and the varieties of *L. tricolor* are in cult., the finest of which is *L. Cammii*, Hort., which combines the bright yellow fls. of *L. aurea*, with the habit of *L. pendula*." Var. **supérba,** Hort., is described as a very large form with boldly colored fls. Var. **d'Ancônæ,** Hort., is a form with light yellow fls. tipped green and purple.

BB. *Fls. not drooping, all erect or at least spreading.*

5. **orchioìdes,** Ait. Bulb globose, to 1 in. diam.: lvs. usually 2, strap-shaped, often spotted, 1 in. wide, clasping the base of the st.: peduncle and infl. 6–12 in.; fls. white, yellow, red or blue, all ascending, the perianth only about ⅓in. long; stamens and style included; inner segms. somewhat longer than outer. B.M. 854; 1269. L.B.C. 11:1076 (as *L. mutabilis*). "The most striking color forms," says Baker, "are **atroviolàcea,** hyacinth-blue; **virénti-flàva,** greenish yellow, and **mutábilis,** inner segms. dull yellow, tipped red-brown."

6. **glaucìna,** Jacq. Bulb globose, 1 in. diam.: lvs. as in No. 5: fls. long, white, red, yellow or tinged blue, erect-spreading; perianth ½–¾ in. long; stamens and style reaching tips of inner segms. which are longer than outer. B.M. 3552. B.R. 1350; 1945 (both as *L. pallida*).



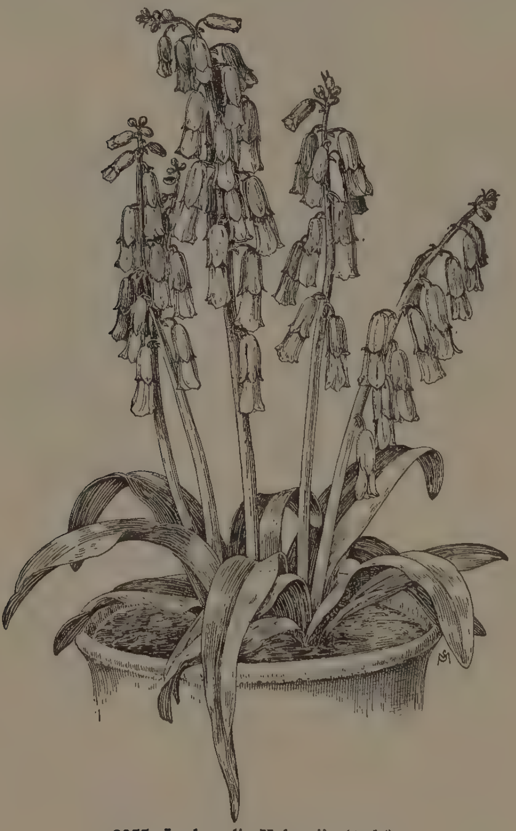
2054. The maze on St. Catherine's Hill, Winchester, England. From a plan made in 1710.

7. **liliflòra,** Jacq. Bulb globose: lvs. 2, lanceolate and falcate, about 1 in. broad, with pustules on the face: peduncle and infl. about 12 in., bearing 12–20 densely racemose fls. which are white; perianth ¾in. long, all the segms. spreading, the outer longer than the inner; stamens equaling inner segms. G.C. III. 38:259.

AAA. *Perianth campanulate or oblong-campanulate, not oblique or ventricose.*

B. *Infl. dense, spike-like.*

8. **pustulàta,** Jacq. Bulb ½in. diam.: lvs. 2, fleshy, pustulate or blistered on the face, lanceolate: peduncle 3–6 in.; fls. white or faintly tinged red, in a dense spike-like raceme 2–3 in. long; perianth ⅓in. long; outer segms. slightly longer than inner, and stamens somewhat exserted. B.M. 817. Perhaps synonymous with No. 11. Var. **violàcea,** Hort., is cult.



2055. Lachenalia Nelsonii. (×½)

BB. *Infl. looser, evidently racemose.*

9. **unifòlia,** Jacq. Bulb globose, small: lf. 1, linear-subulate and erect, brown-banded and clasping at the base: peduncle and infl. 6–12 in. long, carrying a lax 6–20-fld. raceme; fls. white, or more or less tinged with red or blue; perianth about ½in. long; inner segms. protruding, and the stamens of similar length. B.M. 766.

10. **convallarioìdes,** Baker. Bulb globose, ½in. or less long: lf. 1, linear and erect, channelled: peduncle 4–6 in. long, bearing fls. in a short lax raceme; perianth ⅛in. long, purplish becoming white; inner and outer segms. about same length; stamens included; fls. with heath-like odor. There is a var. **robústa,** Baker, more robust, with 20–30 fls., and lvs. rarely 2.

11. **pállida,** Ait. (*L. lùcida,* Ker. *L. racemòsa,* Ker). Bulb globose, ½in. diam.: lvs. 2, pustulate or blistered, strap-shaped: peduncle 6 in. long, bearing a moderately dense raceme 2–3 in. long; fls. white, the perianth ¼in. long; outer segms. tipped green, shorter than the inner segms.; stamens equaling inner segms. B.M. 1372; 1517.

L. víridis, Thunb.=Dipcadi filamentosum.—Various species have been more or less cult. under the name Scillopsis, but they belong in Lachenalia. The generic names Orchiops and Orchiastrum also belong here.

Wilhelm Miller.
L. H. B.†

LACTÙCA (from the old Latin name *lac;* referring to the milky juice). *Compósitæ.* Lettuce. A well-known group of hardy annual or perennial herbs, mostly native of the northern hemisphere.

Plants 2–4 or more feet high, with alternate, variously shaped lvs. and small-panicled heads of yellow, white or blue fls.: involucre cylindric, its bracts imbricated in several series; receptacle flat, naked; rays cut off even at apex, and 5-toothed.—More than 200 specific names have been given to the genus, probably half of which are synonyms with but only 8 or 9 known in cult., and these are doubtless forms of but 2 or 3 species. Aside from garden lettuce, only 1 species appears to be in the trade, though wild plants of other species are often gathered for medicinal purposes. All of the species possess narcotic and sedative properties, the sedative known as lactucarium, or lettuce-opium, being obtained principally from the European species, *L. virosa.* Lettuce has been known and used as a salad from a very remote period. It is said to have been served at the tables of Persian kings 400 B. C. See *Lettuce.*

A. *Fls. yellow.*

satìva, Linn. Lettuce. An annual plant, not known in the wild state but generally supposed to have originated from *L. Scariola,* Linn., in Asia. There are many garden forms assuming an endless variety of forms but which may be divided into 4 rather distinct types.

Var. **capitàta,** Hort. (*L. capitàta,* DC.). Common Cabbage Lettuce. Lvs. entire or sparingly dentate, broad, rounded, yellowish or brownish green, more or less wrinkled and in some garden varieties much curled, spreading, 6–14 in., usually quite compact.

Var. **intybàcea,** Hort. (*L. intybàcea,* Jacq. *L. quercìna,* Linn.). Cut-leaved Lettuce. Lvs. 6–10 in. long, deeply and irregularly cut on the edges, loosely spreading.

Var. **romàna,** Hort. Cos Lettuce. One to 2 ft. high: lvs. entire or sparingly dentate, much longer than broad, quite erect, forming a cylindrical or conical-shaped plant.

Var. **angustàna,** Hort. (*L. angustàna,* Hort.). Lvs. 1–2 in. wide, 6–12 in. long, entire, slightly spreading in habit.

AA. *Fls. blue or purple.*

Plumièri, Gren. & Godr. St. about 6 ft., stout: lvs. much cut, broadly oblong, bluish on the under side: fl.-heads terminal, corymbose, the rays purple. S. France. June–Aug.

L. Bourgæi (Boiss.), is a thick-stemmed bristly-lvd. perennial often 6 ft. tall: heads small, with pinkish bracts and lilac rays. Medit. region.—*L. canadénsis,* Linn. Biennial or annual 4–9 ft. high: lvs. entire or nearly so. Wild plants often gathered for salad.—*L. perénnis,* Linn. Root perennial, 2–3 ft. high: lvs. 8–10 in. long, deeply cut: fls. large, light blue. Native of Eu.—*L. Scarìola,* Linn. Prickly Lettuce. Annual or biennial, sometimes 6 ft. high, the st. stiff and often paniculately branched: lvs. 1–2 in. wide, 4–6 in. long: fls. yellow, inconspicuous. Intro. from Old World, and now a widely distributed weed.

H. C. Irish.
N. Taylor.†

LADY'S EARDROPS: Short-flowered fuchsias. **L. Garters:** *Phalaris arundinacea* var. *picta.* **L. Mantle:** *Alchemilla vulgaris.* **L. Slipper:** *Cypripedium.* **L. Smock** or **Meadow-Cress:** *Cardamine pratensis.* **L. Tresses:** *Spiranthes.*

LǼLIA (meaning uncertain). *Orchidàceæ.* A useful and attractive group of orchids, mostly with large, showy flowers borne singly or in two- to many-flowered racemes, which arise from the top of one- to two-leaved pseudobulbs. The plants greatly resemble cattleyas and differ only by the presence of eight perfect pollen masses instead of four.

Leaves oblong, coriaceous or fleshy, not plicate: pseudobulbs terminating the annual growth, ovate, clavate, fusiform or st.-like, long or short, consisting of 1 to several thickened internodes, or of slender and quill-like form with merely a small bulbous swelling at base, sheathed with scales and bearing 1 or 2 lvs. at the summit: sepals subequal, free, spreading; petals wider and sometimes longer, spreading; all usually plane; labellum free from the base of the column, more or less distinctly 3-lobed, the lateral lobes short, erect, folding over the column; middle lobe long, expanded, lanceolate-ovate, etc.; column concave in front, and thus narrowly 2-winged on the edges; pollinia 8, 4 in each locule; scape terminal, long or short, bracted.—About 30 species, dispersed in the maritime provinces of Mex. and Guatemala and in S. Brazil. No species is common to the two widely separated regions. A single species, *L. monophylla*, inhabits the mountains of Jamaica. In their native homes the plants are often found clinging to bare rocks and trees, where they are exposed to the full force of the tropical sun, and, in the wet season, to daily drenching rains. Some of the species grow at great altitudes. Thus, *L. autumnalis* var. *furfuracea*, is always found in alpine regions at elevations of 7,500–8,500 ft. For a list of cult. kinds, see R. A. Rolfe, G.C. III. 7:107, 256, 333, 355; 8:241, 652.

Lælia may be conveniently divided into groups, as follows:

Group I (species 1–10).—Pseudobulbs rounded, pyriform or ovate. The plants of this section are medium-sized, with the pseudobulbs terminating each year's growth, sessile at intervals on the rhizome, and sheathed at least at first with bract-lvs. The scape, except in *L. grandiflora*, is long and slender, erect, nodding or subhorizontal, and bears at its end 1 or 2 fls. (*L. anceps*), or a raceme of 2–7 fls. (*L. albida*). *L. grandiflora*, placed here on account of its thickened pseudobulbs, bears greater resemblance to the members of the next group.

Group II (species 11–13).—Pseudobulbs short-cylindrical, st.-like, or swollen-jointed, i. e., consisting of several internodes and sheathed with bracts. These plants are of dwarf habit, bearing 1–2 very large fls. on short scapes, so that the top of the fl. scarcely exceeds the lvs., which are oblong, about 6 in. long, and leathery.

Group III (species 14–23).—Pseudobulbs long-oblong, fusiform or clavate, tapering below to a sheathed and jointed stalk. This group contains the largest and most showy lælias. The pseudobulbous sts. are tall and tufted, a foot or more in length, forming robust, compact, almost bushy plants. The flowering sts. of *L. superbiens* are said to attain a height of 12 ft. The racemes bear 3–7 large, handsome fls.

Group IV (species 24–26).—Pseudobulbs slender, reed-like and tufted, clothed with scales and often somewhat swollen at base. This group includes a few species which are very distinct on account of their bright scarlet or orange-colored fls. and slender, reed-like pseudobulbs. *L. monophylla* is perhaps the smallest of all lælias, being scarcely over 6 in. high, with pseudobulbs about as thick as a crow-quill. One variety of *L. cinnabarina* has purple fls.

Cultivation of lælias. (E. O. Orpet.)

These orchids have ever held an important place in gardens, and were it not for the trifling generic distinction of having double the number of pollen-masses of the cattleya, they would have been known as a part of the last named, the ease with which both have been hybridized even from the beginning proving the close affinity; and one authority at least is willing to merge the two, were it not for the mixing up it would cause in garden nomenclature. The Brazilian species, *L. purpurata* and *L. crispa*, are strikingly beautiful, easy of culture, and are long-lived in gardens. These were the first to be used by the hybridist, and the multiple crosses made since, with the later addition of *L. tenebrosa*, show evidence of the gorgeous coloring of the labellum due to the lælia parentage.

It has always been the impression that the Brazilian lælias require very much warmth to enable them to grow well. This has been proved to be an error, as stronger growth is made in an intermediate temperature. The plants get an absolute rest in winter, flower better and grow stronger when kept at a temperature of about 50° in winter.

The Mexican kinds that mostly flower in midwinter, such as *L. anceps* and its white forms, will do equally well in a similar house, but are best grown outdoors in summer in the partial shade of overhanging trees, giving a spraying of water overhead at evening of each hot day. This has been found to be the only way to get the white forms to bloom freely, as they need special treatment and thorough ripening to secure good results. Removal indoors should take place before frost; cool nights seem to invigorate them, but while they experience slight frosts in Mexican uplands, it is harmful here. These lælias make an abundance of roots, and the plants should be kept off the ground to avoid the danger of slugs. If these gain access, soak the pots or baskets in water for an hour and the slugs will appear and can be caught.

The repotting of lælias must be done in early spring, or just before the appearance of the new bunches of roots at the base of the growths. Native-born species have a regular way of living, but the hybrids have a go-as-you-please habit, due perhaps to their mixed origin, that makes the repotting an operation that lasts throughout the year. Flowers are produced at all seasons, while, with introduced plants, their blooming is as fixed as the days of the year. This makes it hard to make a rule when to repot or separate plants; but, should the roots begin to get outside the receptacle, it is wise to give the plants more space. Good firm osmundine is the best material, as these are strictly epiphytal plants. Imported specimens are received with mats of dwarf polypodium attached, and these often grow with the plants in cultivation, giving a clue to the best way to treat them afterward. The other Mexican species, *L. Gouldiana*, *L. autumnalis* and *L. albida*, are not so durable in gardens as some others. They are most valuable midwinter-flowering orchids; they need similar culture as that given to *L. anceps*, but have to be replaced by new specimens after a few years, as they are not permanent.

There are many pretty dwarf-growing species, *L. præstans*, *L. Dayana*, *L. pumila*, *L. grandiflora*, *L. Jongheana* and others, that require extra care to keep them in health, and this care is largely in the matter of moisture. The plants are small, need shallow pans and to be suspended close to the roof glass where they dry out speedily, and unless moisture is given regularly, the health of the plants soon weakens. The drying out is desirable, for the plants experience this on rocks or trees in their native habitat, but there they have the benefit of the night dews that amount to a shower of moisture; this is easily imitated by spraying over the plants each dry evening. The roots will take this up during the night, and be fortified for the succeeding day. If one examines the aërial roots of *L. anceps*, they will be found to be in segments, some longer than others, the longer ones being those formed on a dull or wet day when evaporation was slower and the tender-growing tips could grow longer. This is suggestive in a cultural way.

GROUP I.

A. *Pseudobulbs not compressed or edged.*
  B. *Fls. bright yellow* .... 1. **flava**
  BB. *Fls. rose, purple or white.*
    C. *Scape scarcely equaling the lvs.: dwarf plants, with very large fls.* ... 2. **grandiflora**
    CC. *Scape slender, much exceeding the lvs.*
      D. *Fls. small, white or pale yellow* ... 3. **albida**
      DD. *Fls. large, rose-purple; rarely white.*
        E. *Lip 2-keeled* .... 4. **autumnalis**
        5. **Arnoldiana**
        EE. *Lip 3-keeled.*
          F. *Lvs. oblong* .... 6. **Eyermanniana**
          FF. *Lvs. lance-linear or oblong-linear* .... 7. **Crawshayana**
          8. **Gouldiana**
AA. *Pseudobulbs compressed and edged.*
  B. *Lip with a broad, elevated line down the center; ovary viscose* .... 9. **anceps**
  BB. *Lip with 3 keels; ovary not viscose*..... 10. **rubescens**

1. **flàva,** Lindl. (*L. cauléscens,* Lindl.). Lvs. 3–5 in. long, oblong-lanceolate, acute, very thick and stiff: scape 1 ft., erect, bearing 4–8 bright yellow fls. 2–2½ in. diam.; sepals and petals spreading, oblong-lanceolate, obtuse or subacute; labellum not longer than the petals; middle lobe recurved, crisped and undulate, having 4 elevated ridges running down the center; lateral lobes obtuse. Autumn. Brazil. B.R. 28:62.

2. **grandiflòra,** Lindl. (*L. majàlis,* Lindl.). Lvs. solitary, oblong, coriaceous, 6–7 in. long: fls. solitary, rarely 2, on a short peduncle, scarcely equaling the lvs., 5–8 in. across, showy, rose-lilac; sepals lanceolate, plane; petals oblong, acute, shorter and much broader than the sepals; middle lobe of the labellum large, expanded, emarginate, center white, shading to lilac at the margin, spotted with dark lilac; side lobes small, white inside, streaked with lilac. May, June. Mex. B.M. 5667. B.R. 30:30. P.M. 12:1. G.C. II. 19:628.—A magnificent orchid. Var. **âlba,** Reichb. f. White. A.G. 19:109; 20:371. G.C. III. 40:45. Var. **màjus** is advertised.

3. **álbida,** Batem. Lvs. lance-linear, acute: scape twice as long as the lvs.; fls. 2 in. across, pure transparent white except a yellow streak down the lip and a few crimson dots at its base, sweet-scented; sepals lanceolate, spreading; petals similar but broader, all very acute; labellum 3-lobed; side lobes small, erect; middle lobe large, round-ovate, reflexed. All autumn and winter. Oaxaca, Mex. B.M. 3957. B.R. 25:54. Gn. 35:314.—The first white-fld. species discovered. Var. **sulphùrea,** Reichb. f. Larger: fls. sulfur-yellow, with a rose-colored border on the middle lobe, and rose spots on the inner surface of the side lobes. Var. **bélla,** Hort., ex Williams, not Reichb. f. Fls. larger than the type; sepals and petals creamy white, faintly bordered with lilac; lip white, the middle lobe broadly bordered with deep rose and having 3 yellow ridges down the center. Var. **rôsea,** Hort. Fls. rose-colored. Var. **màjus** is advertised.

4. **autumnàlis,** Lindl. Lvs. oblong-linear, obtuse, coriaceous, 5 in. long: scape 1½–2 ft. long, 5–6-fld., with sheathing scales; fls. showy, fragrant; sepals lanceolate-acuminate; petals oblong-lanceolate, undulate; lateral lobes of the labellum large, erect, rotund-truncate, whitish; middle lobe obovate, obtuse, apiculate, recurved, deep purple; disk with 2 narrow yellow lamellæ. In color and general appearance much like *L. anceps,* but the segms. lack the green ribs. Autumn. Mex. B.M. 3817. B.R. 25:27. I.H. 1:17. P.M. 6:121. G.C. 1872:1009.—Grows on bare rocks and stunted trees in most exposed situations, often at great altitudes. Less valuable than *L. anceps.* Var. **furfuràcea,** Rolfe (*L. furfuràcea,* Lindl.). This seems to be a dwarf alpine form, with the ovary more scurfy and the petals unusually broad. It is always found at great elevations, occurring frequently at 7,500–8,500 ft. Intermediate forms exist. B.M. 3810. B.R. 25:26. Var. **atrórubens,** Backh. Pseudobulbs short: fls. large, deep rose or magenta, darker toward the ends of the segms. and the labellum; base of the labellum and lateral lobes white. Gn. 17:368. Var. **venùsta,** Hort. Goldring. In habit resembles var. *atrorubens:* stalk 2–3 ft.: fls. large, rosy mauve. Gn. 25:366. Var. **Fourniéri,** André. Fls. about 6–7 in. across; sepals revolute at the summit, purple-red; petals rhomboid, of the same color, all paler toward the base; labellum white, with the middle lobe colored like the segms. Larger than var. *atrorubens.* R.H. 1896:548. Var. **âlba,** Hort. Fls. pure white.

5. **Arnoldiàna,** Manda. Pseudobulbs 4–6 in. long, pyriform, deeply furcate, 2-lvd.: lvs. 5–7 in. long, leathery, lanceolate, thick and dark green: scape 1–4 ft. long, 3–11-fld.; sepals oblong-lanceolate, pointed; petals broader, ovate, all somewhat reflexed, rose-colored; middle lobe of the labellum reflexed, deep rose-purple, paler toward the center; throat with 2 yellow keels, spotted purple; lateral lobes straight, pale rose or white.—A species closely related to *L. autumnalis,* from which it differs in having bulbs growing erect and rigid lvs. and in the absence of the fetid odor of *L autumnalis.* (W. A. Manda.) Mex. A.F. 5:303. Var. **Fórstermannii,** Hort. Identical with the type, but has pure white fls., with a tinge of delicate pink on the ends of the segms. (W. A. Manda.)

6. **Eyermanniàna,** Reichb. f. (*L. autumnàlis* × *L. grandiflòra,* Reichb. *L. autumnàlis* × *L. albida,* Rolfe). Natural hybrid. Pseudobulbs like those of *L. grandiflora:* lvs. oblong, acute, very leathery, 6 in. long and 2 in. broad: racemes bearing 3–4 fls. up to 4 in. across (as large as those of *L. Gouldiana,* but smaller than *L. autumnalis*), rose-purple (white suffused with bright rosy crimson); sepals lance-oblong, acute; petals broadly oblong or almost rotund, obtuse; side lobes of the labellum oblong; middle lobe rounded, wavy, white bordered with rose and having 3 yellow keels on the disk fading to whitish on the blade. G.C. III. 4:109.

7. **Crawshayàna,** Reichb. f. Natural hybrid. Pseudobulbs and lvs. as in *L. albida:* scape few (2)-fld., long as in *L. anceps,* but thinner and with shorter, narrower sheaths; sepals and petals narrower than in *L. anceps,* of a fine amethyst-color; labellum open near the column; side lobes obtuse-angled, antrorse, rich purple at the tips; middle lobe cuneate, abruptly blunt, lower half rich purple; throat yellow, veined with purple, 3-keeled. According to Reichb., a hybrid between *L. anceps*(?) and *L. autumnalis*(?) or *L. albida* and *L. anceps.* J.H. III. 30:67; 54:27 (as *L. anceps* var. *Crawshayana*)

The plant there figured is probably the species in question, although, according to the figure and the accompanying description, the sepals and petals are wider than those of *L. anceps*.

8. **Gouldiàna,** Reichb. f. Pseudobulbs ovate, 2-lvd.: lvs. oblong-linear: scape slender, 1–2 ft. long, bearing as many as 6 deep rose-purple fls. resembling those of *L. anceps;* sepals lance-oblong, pointed; petals broader, ovate, acute; middle lobe of the labellum large, deeply colored, throat white and veined; side lobes white. Dec., Jan. Mex. G.C. III. 7:169.—A useful species, large plants often bearing 5–10 racemes. Perhaps only a variety of *L. autumnalis*.

9. **ánceps,** Lindl. Fig. 2056. Pseudobulbs scattered on the rhizome, ovate: lvs. 5–9 in. long, oblong-lanceolate: scape from the top of the pseudobulbs, 1½–2 ft. long, clothed with keeled scales and bearing 1–2 very showy, purplish rose-colored fls.; sepals lanceolate-acuminate; petals ovate-acuminate, all with a greenish line on the back; labellum inside of the lateral lobes yellow, with red marks; middle lobe oblong, acute, deep purple, white on the disk, with a thickened yellow keel terminating in 3 ridges. Mex. B.M. 3804. B.R. 1751. G.C. II. 24:405. P.M. 4:73. O.R. 15:145.—One of the most beautiful species of lælia, possessing many fine varieties. Var. **Barkeriàna,** Lindl. Sepals and petals subequal; middle lobe of the labellum rather narrow, acute. B.R. 1947. F.S. 11:1100. Gn. 25:534. Var. **Dáwsonii,** J. Anders. Scape 2–3 ft. long, 2–3-fld.; fls. white; interior of the labellum marked with radiating purple lines, with the usual yellow ridge. Juquila, Mex. Gn. 25:534. G.C. III. 1:424. S.H. 2, p. 175. F.M. 1871:530. Var. **álba,** Reichb. f. Sepals and petals as in var. *Dawsonii;* fls. pure white, with the disk of the lip pale yellow. Dec., Jan. G.C. III. 1:485; 15:172. J.H. III. 50:179. Var. **Hilliàna,** Reichb. f. Sepals and petals white; front lobe of the labellum bilobed emarginate. I.H. 33:584. Gn. 25:534. G.C. III. 1:425. Var. **Williamsii,** Hort. Pure white, narrower than in var. *Stella;* labellum white, large, with the disk and throat yellow, marked with crimson-purple. G.C. III. 1:349. Gn. 25:534. Var. **Lageriàna,** Hort. White, suffused with rose; lip dark lavender, mottled and streaked purple, the throat yellow, purple-veined. Var. **Leeàna,** Reichb. f. Fls. white, smaller than in *L. anceps;* petals very narrow and very acute; side lobes of the labellum blunt; middle lobe small, triangular, wavy, with a thick, well-developed keel; throat yellowish, veined with reddish purple. Var. **Schroederiàna,** Reichb. f. Fls. unusually large; sepals, petals and middle lobe of the labellum pure white; side lobes and throat streaked with broad lines of purplish crimson. Gn. 44:284. G.M. 33:813. G.C. III. 29:94. Var. **Sanderiàna,** Reichb. f. Fls. white; disk of lip crimson. G.C. III. 1:281; 25:136; 43:216. O.R. 9:9; 17:frontis. Gn. 44:284. G.M. 37:88. Var. **Veitchiàna,** Reichb. f. Sepals and petals white; disk of the labellum yellow, veined with brown; lateral lobes and anterior part of the middle lobe veined with purple. Gn. 25:534 (as *L. Veitchii*). Var. **Stélla,** Reichb. f. Fls. pure white; labellum with yellow throat, marked with light crimson lines. G.C. III. 1:280 and 8:500. Var. **Amesiàna,** O'Brien. Sepals and petals broad, feather-veined with mauve; labellum white; middle lobe crimson-purple. G.C. III. 23:59. Var. **Ashworthiàna,** O'Brien. Sepals pure white, lance-oblong; petals broadly ovate, also white; front lobe of the labellum broad, expanded, white, with a few blue dots and yellow keels on the throat; side lobes with lines of slaty blue. G.C. III. 15:103. J.H. III. 28:125. Var. **waddoniénsis,** Hort. Fls. pure white; side lobes of the lip marked with purple lines, disk yellowish. J.H. III. 56:349. G.C. III. 23:125. G.M. 41:115. Var. **Chamberlainiàna,** Hort. Sepals and petals soft rosy lilac; base and side lobes of lip purple-lined, the middle lobe a glaring crimson-purple, the callus orange. G.C. III. 31:71; 49:78. G.M. 45:101. Var. **Percivaliàna,** Reichb. f. Fls. small, but freely produced; sepals and petals white, tinged with bluish pink; lateral lobes of the labellum deep purple at the tips and spotted; throat yellow, with purplish crimson lines; middle lobe creamy yellow at the base; apex purplish. Gn. 25:534. Var. **delicàta,** Hort. ex Williams. Labellum white, suffused with mauve; throat orange-yellow; sepals and petals rose, mauve or lilac. Var. **ròsea,** Reichb. f. A variety having bright rose-colored fls., with the margins of the labellum darker rose. Gn. 25:534. Var. **grandiflòra,** Williams. A robust form resembling the type. G.C. III. 3:105. Var. **holochìla,** Rolfe. Sepals and petals nearly alike, pale lilac; lip petaloid, elliptical-lanceolate, light purple, yellow and white at the base. G.F. 4:173. Var. **Scottiàna,** Warner and Williams. Sepals and petals mauve; labellum deep purple, with a yellow throat. Var. **moràda.** This is a name under which importations of large, highly colored forms of *L. anceps* were sold by the Liverpool Hort. Co., England, as var. *grandiflora.*—Many other varieties appear under Latin names.

2056. Lælia anceps. (×⅓)

10. **rubéscens,** Lindl. (*L. acuminàta,* Lindl. *L. pedunculàris,* Lindl.). Pseudobulbs ovate to subrotund, clustered, sometimes rugose, 1-lvd.: lvs. oblong to lance-oblong, emarginate, 4–5 in. long: scape slender, jointed, sheathed with brown scales at the joints, 1 ft. long, with 2–8 graceful, fragrant fls.; sepals spreading, linear-oblong, acute; petals slightly longer and twice as wide, undulate; labellum as long as the petal; middle lobe of the same form but more undulate and with a stain of yellow on the disk, purplish red on the inner surface. B.M. 4905 and 4099. B.R. 26:41; 27:24; 31:69. F.S. 1:9; 7:742. P.M. 10:49. O.R. 14:41; 19:72.—A slender, graceful plant with small, whitish, lilac-tinted or rose-colored fls. much smaller than those of *L. anceps*.

GROUP II.

A. *Pseudobulbs ovate, evidently thickened.*
  B. *Lip with about 7 undulate keels* ...... 11. **Jongheana**
  BB. *Lip without or with plane keels* .... 2. **grandiflora**
AA. *Pseudobulbs oblong, more st.-like.*
  B. *Fls. greenish yellow* .... 15. **glauca**
  BB. *Fls. bright colored or white.*
    C. *Labellum firm, fleshy; lateral lobes convolute over the column* .... 12. **pumila**
    CC. *Lateral lobes of the lip resting on the middle lobe* .... 13. **Leeana**

11. **Jongheàna,** Reichb. f. Rhizome with remarkably thick root-fibers: pseudobulbs ovate-oblong, 1-lvd.: lvs. broadly oblong, 3–5 in. long, very thick and dark green: scape stout, shorter than the lf., 1–2-fld.; fls. 4 in. diam., bright amethyst-color; sepals linear-lanceolate, acute; petals broadly oblong-obtuse; labellum convolute; lateral lobes very shallow; middle lobe emarginate, white and crisp, with about 7 golden-yellow undulate ridges in the throat. Brazil. B.M. 6038. R.H. 1873:290. G.C. 1872:425. O.R. 12:273.—A dwarf species with remarkable leathery lvs. Said to equal *L. grandiflora* and *Cattleya Mossiæ.* Rare in cult. Many varieties are listed under Latin names.

12. **pùmila,** Reichb. f. (*Cáttleya pùmila,* Hook. *C. marginàta,* Paxt. *L. prǽstans,* Lindl. & Reichb. f. *L. Dayàna,* Reichb. f. *L. Pinélli,* Hort.). Pseudobulbs small, st.-like, with 1 oblong to linear-oblong lf. 5–6 in. long: peduncle shorter than the lvs., each bearing a single, large, drooping, rose-purple fl.; sepals oblong, acute; petals ovate-oblong, broader, undulate; labellum very involute; lateral lobes subquadrate, middle lobe short, emarginate, waved and crisped; throat yellow, apex rich purple. A pretty dwarf species from Brazil, very variable and useful. B.M. 3656, 5498. B.R. 30:5. F. 1850:89 (as *Cattleya spectabilis*). G.C. II. 23:597; III. 36:354.—Many variations of this plant have been described as distinct species, although botanically but one species. Some of them are well-marked horticultural varieties. Var. **prǽstans,** Veitch (*L. prǽstans,* Lindl. & Reichb. f.). A large-fld., highly-colored variety, with the sepals and petals much broader than in the type; labellum rich purple, very rigid and fleshy, lines almost obsolete. B.M. 5498. Gn. 53, p. 550. Var. **marginàta,** Hort. (*Cáttleya marginàta,* Paxt.). Fls. large; sepals and petals rose-crimson; labellum with a white border, crisp. Brazil. P.M. 10:265. I.H. 6:193 (as *Cattleya pumila* var. *major*). F.S. 18:1900. G.C. III. 22:262. A.G. 11:158. Var. **Dayàna,** Dean (*L. Dayàna,* Reichb. f.). Sepals and petals rose-purple; labellum with a deep purple margin. Earlier than the type. Brazil. R.H. 1890, p. 490. F.M. 1877:249. Var. **álba,** Hort. Fls. like var. *præstans,* but pure white with the base of the lip yellow. G.C. III. 21:11. J.H. III. 34:27; 43:349; 49:409, 475.

2057. Lælia purpurata. (×⅙). No. 22.

13. **Leeàna,** Reichb. f. Hybrid: pseudobulbs cylindrical, somewhat swollen, 1-lvd.: lvs. cuneate-oblong, very coriaceous: sepals and petals spreading, ligulate, acute, somewhat undulate, rose-color, lateral lobes of the labellum semi-ovate, acute, the tips resting on the middle lamella, white, tips purple; middle lobe broad, obcordate. Sept. "Natural hybrid of *L. marginata* and ———?" (Hansen).—As this plant has 4 pollinia, it is probably nearer Cattleya. It was imperfectly described by Reichb. as a doubtful hybrid.

GROUP III.

A. *Fls. greenish yellow.*
  B. *Labellum deeply fringed on the margin*..................14. **Digbyana**
  BB. *Labellum not fringed.*
    C. *Evidently 3-lobed*..............15. **glauca**
    CC. *Obsoletely 3-lobed*..............16. **virens**
AA. *Fls. all yellow*..................17. **xanthina**
AAA. *Fls. with only the sepals and petals tawny yellow; labellum some other color*..........................18. **grandis**
AAAA. *Fls. purple, rose or white.*
  B. *Labellum with several prominent toothed crests*..................19. **superbiens**
  BB. *Labellum destitute of crests.*
    C. *Petals and labellum waved and crisped.*
      D. *Fls. uniformly purple*.......20. **Boothiana**
      DD. *Fls. white and purple.*
        E. *Lip ovate-acuminate*.......21. **crispa**
        EE. *Lip rounded*.............22. **purpurata**
    CC. *Sepals and labellum plane, or nearly so*....................23. **Perrinii**

14. **Digbyàna,** Benth. (*Brassávola Digbyàna,* Lindl.). Pseudobulbs elongate, st.-like, 1-lvd.: lvs. elliptical, thick, fleshy, plane, slightly keeled: peduncle with a solitary, very large, fragrant fl. 3–5 in. across; sepals and petals similar, oblong, spreading, pale purplish green; petals slightly broader; labellum very large-cordate, entirely surrounding the column, white or cream-colored, with the margin cut into a broad laciniate fringe, which makes the fl. very striking. July, Aug. Honduras. B.M. 4474. B.R. 32:53. F.S. 3:237. G.C. III. 18:153. G.M. 46:307.—A slow-growing orchid.

15. **glaùca,** Benth. (*Brassávola glaùca,* Lindl.). St. short, creeping: pseudobulbs short, oblong, st.-like, compressed and sheathed with scales, bearing a single oblong, glaucous, very thick and leathery lf.: fls. usually single, on a stalk shorter than the lf., fragrant; sepals and petals spreading, oblong-lanceolate, obtuse, greenish yellow; labellum with a short claw surrounding the column, then expanding into a large 3-lobed limb, yellowish white, streaked with red in the throat. Mex. and Guatemala. B.M. 4033. B.R. 26:44. G.C. III. 7:357.

16. **vìrens,** Lindl. Plants about 6 in. high: fls. 1 in. across; sepals suberect, ovate; petals lanceolate, subequal; labellum obsoletely 3-lobed, cucullate; apex ovate, crisp, with obscure raised lines toward the base. Brazil.—The fls. are pale yellowish green, of no beauty.

17. **xanthìna,** Lindl. Lvs. oblong, longer than the fusiform pseudobulb: raceme 3–5-fld.; fls. 3 in. across, buff-yellow except the lip, which is white in front streaked with crimson-purple; sepals and petals subequal, oblong-obtuse, undulate, leathery and convex; labellum nearly quadrate when spread out, without raised veins. Brazil. B.M. 5144. F.S. 23:2418.—Intro. 1858. A second-rate species.

18. **grándis,** Lindl. & Paxt. Pseudobulbs st.-like, 1-lvd., 1 ft. high: lvs. rigid, oblong-lanceolate: scape erect, bearing 2–5 fls. 4 in. across; sepals and petals lanceolate, the latter a little broader, slightly curled or twisted; labellum white; front lobe large, bell-shaped, crenate-toothed, veined with purple. Spring. Brazil. B.M. 5553. F.S. 7, p. 238, and 23:2473.—A curious species with the sepals and petals colored tawny yellow, contrasting strongly with the whitish purple-veined lip. Var. **tenebròsa,** God. Lebeuf. Sepals and petals citron-yellow, less undulate; labellum trumpet-shaped, purple, with a broad border of white with many purple veins. G.C. III. 14:221. G.M. 36:531.

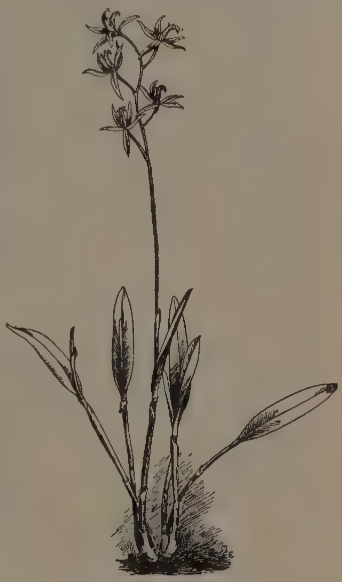
19. **supérbiens,** Lindl. Pseudobulbs 1 ft. or more in length, oblong, with 1 or 2 coriaceous oblong lvs. equaling the pseudobulbs in length: scape drooping, 5–6 ft. long, bearing a globose cluster of 10–20 fls. each about 6 in. diam.; sepals and petals nearly equal, spreading, oblong-lanceolate, obtuse, lilac-purple, paler below; labellum as long as the segms., middle lobe broad obcordate, waved and crisped; disk with several prominent toothed crests, yellow, deep crimson-purple on the margins; side lobes yellow with purple margins and stripes. Guatemala. B.M. 4090. F.S. 11:1178, 1179. P.M. 11:97. R.H. 1886:324.—A very large plant.

20. **Boothiàna,** Reichb. f. (*L. lobàta,* Veitch. *Cáttleya lobàta,* Lindl.). A strong-growing plant: pseudobulbs clavate, furrowed, 1-lvd.: lvs. lanceolate-oblong, about as long as the scape: scape 8–10 in. long, from the axil of the lf., 2–5-fld.; fls. about 5 in. across, uniformly violet-purple with rich crimson veins on the lip; sepals lanceolate, with reflexed margins; petals broad, oblong, undulate, crisp; labellum cucullate, the middle lobe reflexed, all beautifully waved and crisped. Much like *L. crispa* in habit. April, May. S. Brazil. R.H. 1874:331 (as *L. Rivieri*). G.C. 1848:403; III. 10:577. F.S. 20, p. 132. A.G. 13:608. O.R. 12:265.—This plant is not free-flowering, hence it is little cult., although a beautiful and distinct species.

21. **críspa,** Reichb. f. (*Cáttleya críspa,* Lindl.). Pseudobulbs clustered, elongate-clavate, 1-lvd.: lvs. large, 1 ft. long, oblong-lanceolate, emarginate: scape with 5–6 large, handsome, fragrant fls.; sepals linear-oblanceolate or spatulate, acute, margins revolute; petals much broader, with the margins beautifully waved and crisped; labellum standing forward, recurved at the apex; side lobes rounded, white, yellow at base, streaked with red; middle lobe long, ovate-acuminate, deep purple inside, veined, all remarkably waved and crisped. Summer. On lofty trees fully exposed. Brazil. B.M. 3910. B.R. 1172. Gn. 48, p. 504. J.H. III. 33:197. P.M. 5:5. O.R. 9:201; 17:305.—A fine white-fld. species resembling a cattleya in habit. Var. **Cauwelærtiæ,** L. Lind. Sepals and petals tinged with greenish yellow; base of labellum yellow. I.H. 38:121.

22. **purpuràta,** Lindl. & Paxt. (*Cáttleya Brysiàna,* Lem.). Fig. 2057. Pseudobulbs long-elliptical, 6–8 in. high: lvs. solitary, oblong, leathery, dark green, 1 ft. or more in length: scape erect, 3–7-fld.; fls. very large, 6–8 in. across; sepals linear-oblong, spreading, white, suffused with light rose; petals much broader, ovate, undulate, crisp, base attenuate, colored like the sepals; labellum very large, bell-shaped; middle lobe rounded, undulate, crisp, rich purple with darker veins, throat yellow. A robust plant, whose large fls., borne on strong erect stalks, make it one of the grandest lælias in cult. Spring. Brazil. I.H. 1, p. 54, and 3:83. F.S. 11:1138, 1139. Gn. 54, p. 17; 56, p. 46 (var. Mrs. Measures). G.C. II. 14:45; 20:533. A.F. 6:223. O.R. 15:156. G.M. 57:723 (var. *alba*). Var. **atropurpùrea,** Williams. Sepals and petals deep rose; labellum large, expanded, purple-magenta; throat yellow, veined with purple. Brazil. Var. **Ashworthiàna,** J. Anders. Petals wider than in the type, 2 in. wide, purplish rose, with darker stripes. A highly colored form. G.C. III. 20:39. Var. **Nélisii,** Hort., Versch. Sepals and petals subsessile, the former rose-colored outside; midlobe of the labellum ovate, acute. Much like the type in color. I.H. 15:569. Var. **Russelliàna,** Williams (*L. Russelliàna,* Hort.). Fls. large; sepals somewhat narrow, white, suffused with lilac; petals broader, deeper lilac; labellum large, rose-lilac; throat yellow, marked with rose. Autumn. Var. **Schrœderi,** Reichb. f. Sepals and petals white; labellum white, with a tinge of rose in the center; tube pale yellow, with fine, dark purple lines. I.H. 38:139. Var. **Mandaiàna,** Hort. Pseudobulbs thinner and narrower than in the type: fls. as large as those of the type, pure white, with a faint tinge of pink on the labellum. Var. **prætéxta,** Reichb. f. No description of this plant is available. Many other varieties appear under Latin names.

23. **Pérrinii,** Lindl. (*Cáttleya Pérrinii,* Lindl.). Pseudobulbs elongate: lvs. solitary, oblong, coriaceous, 8 in. long, equaling the st.: fls. showy, 2–3 on a short stalk; sepals oblong-linear, obtuse; petals a little broader, all rose-purple, darker at the tips; middle lobe of labellum cucullate, expanded, oblong, obtuse, undulate, with an inflated fistular cavity at the base, destitute of ridges, color deep crimson; lateral lobes erect, acute, pale. Oct.–Dec. Brazil. B.M. 3711 (as *L. intermedia* var. *angustifolia*). B.R. 24:2. P.M. 13:5. G.M. 37:717. A.F. 13:1196; 31:470.—Fls. rather pale. Var. **álba,** O'Brien. Fls. white, labellum tinged with yellow. There are several pale varieties of this plant.



2058. Lælia cinnabarina.

GROUP IV.

A. *Lvs. solitary.*
  B. *Scape 1-fld*........................24. **monophylla**
  BB. *Scape several-fld*..................25. **harpophylla**
AA. *Lvs. usually 2*......................26. **cinnabarina**

24. **monophýlla,** N. E. Br. Rhizome a matted mass sending up tufts of lf.- and fl.-sts.: flowering sts. 6–10 in. long, as thick as a crow-quill, rigid and erect, bearing a single linear-oblong, obtuse lf. 2–3 in. long, and several sheathing bracts; fls. 1–2 in. across, vivid orange-scarlet; sepals and petals similar, spreading, oblong, subacute; labellum very small, lateral lobes embracing the column, terminal minute papillose on the disk. Mountains of Jamaica, growing on trees at elevations of 3,000–5,000 ft. B.M. 6683.

25. **harpophýlla,** Reichb. f. Hybrid much like *L. cinnabarina.* Pseudobulbs slender, about 10 in. long, each bearing a single lance-linear lf.: raceme short, suberect, bearing 5–10 brilliant scarlet-orange fls.; sepals and petals oblong-lanceolate, acute; middle lobe linear, acuminate, crisp, with a whitish spot. A luxuriant free-flowering species. Feb., March. Brazil. Gn. 24:116. F.M. 1879:372. J.H. III. 43:283.—Probably a hybrid between *L. cinnabarina* and a Brassavola(?), Reichb. f.

26. **cinnabarìna,** Batem. Fig. 2058. Pseudobulbs elongate, cylindrical, but broadest at the base, sheathed with scales, bearing 1–2 linear-oblong, reflexed, acute, coriaceous lvs.: raceme terminal, erect, 15–20 in. long, with

4–5 medium-sized reddish orange fls.; sepals and petals linear-oblong, obtuse, spreading; labellum convolute, reflexed; lateral lobes acute, middle lobe large, oval, crisp. Brazil. B.M. 4302. P.M. 7:193. O.R. 20:361. —A summer-flowering species whose peculiar color and graceful habit render it very ornamental. Var. **crispilàbia**, Veitch (*L. crispilàbia*, A. Rich. *L. Lawrenciàna*, Hort.). Fls. amethyst-purple; labellum darker, finely crisp and undulate: raceme 12–14 in. long, bearing 3–5 fls. A pretty, free-flowering variety.

L. bélla=L. grandiflora × L. purpurata.—*L. Canàri*=L. Digbyana × L. xanthina.—*L. canariénsis*=L. harpophylla × L. anceps. —*L. Còwanii*, Rolfe. Habit of L. cinnabarina, but pseudobulbs taller: fls. yellow, in erect spikes. Brazil.—*L. chamonicénsis*=L. purpurata × L. Jongheana.—*L. Chatínii*=L. Jongheana × L. harpophylla.—*L. crispabròsa*=L. crispa × L. tenebrosa.—*L. Dánielsii*=L. Perrinii × Lc. Schilleriana.—*L. Degeestiàna*=L. Jongheana var. alba × L. flava. Sepals and petals white, the lip yellow. G.C. III. 48:274.—*L. Digbyàno-Móssiæ*=Brassocattleya Veitchii.—*L. édissa*=L. anceps × L. purpurata. G.M. 43:193.—*L. flavìna*=L. pumila × L. flava.—*L. gattonénsis*=L. anceps var. Dawsonii × L. cinnabrosa.—*L. Gílbertii*=L. tenebrosa × Lc. elegans.—*L. Górdonii*. Of doubtful origin. Pseudobulbs about 1 in. long, furrowed after first season.—*L. Gròganii*=L. flava × L. crispa.—*L. Gwéniæ*=L. Jongheana × L. Cowanii.—*L. Johniàna*, Schlecht. Pseudobulbs club-shaped: racemes few fld.; fls. greenish white. Probably Colombia. O. 1912:6.—*L. Latòna*, Hort. Veitch. Sepals and petals light orange-yellow; labellum whitish at base, the rest purple bordered with orange-yellow; middle lobe much undulated. A garden hybrid between L. cinnabarina and L. purpurata. Not advertised in Amer. A. Pericat, Philadelphia, writes as follows of this plant: "Lælia Latona, raised by Veitch, is a beautiful hybrid lælia of a distinct and unusual color, from L. purpurata × L. cinnabarina, the latter being the seed parent. The sepals and petals are of light orange-yellow; lip whitish at the base, the remainder red-purple bordered with orange-yellow, the margin of the apical spreading; lobe is much undulated."—*L. Lúndii*, Reichb. f. Plant small, about 6 in. high: fls. produced on young growth; sepals and petals narrow, white, suffused with lilac; lip 3-lobed. Brazil.—*L. lynwoodénsis*=L. Jongheana × L. harpophylla.—*L. Rógersii*=L. Dayana × L. Cowanii. —*L. Sidneyàna*=L. cinnabarina × L. Jongheana.—*L. Státheræ*=L. purpurata × L. flava.—*L. tenejàlis*=L. grandis var. tenebrosa × L. majalis.

HEINRICH HASSELBRING.

LÆLIOCATTLÈYA (compounded from *Lælia* and *Cattleya*). *Orchidàceæ.* A name proposed by R. A. Rolfe to designate the bigeneric hybrids of Lælia and of Cattleya, which readily hybridize. The species of the two genera have eight and four pollen masses respectively, while the hybrids are irregular in this respect. Many of the plants are natural hybrids, and many others have been produced by artificial crossing. For a list of læliocattleyas, see Rolfe in G.C. III. 6:78, 155. In the following account L.=Lælia; Lc.=Læliocattleya; C.=Cattleya.

The cultivation of læliocattleyas is the same as for lælia and cattleya. It is therefore important to know the parentage in each case, from which one may know whether warm or coolhouse treatment is needed. Many læliocattleyas are of such a vigorous constitution that they are nearly always in growth.

1. **élegans**, Rolfe (*L. élegans*, Reichb. f. *C. élegans*, Morr.). Pseudobulbs terete, st.-like, 15–20 in. high: lvs. solitary, linear-oblong, coriaceous, 10–12 in. long: scape short, stout, 3–7-fld.; fls. 5 in. diam., light or bright rose, fragrant; sepals oblong, acute, often somewhat twisted or with revolute edges; petals much wider, lanceolate, margin somewhat undulate; labellum with the lateral lobes elongate-obtuse, whitish with purple apices, convolute over the column; middle lobe broadened in front, subreniform, margin undulate, crisp, entirely a very deep purple, without raised lines or callosities. May–Sept. Brazil. B.M. 4700. I.H. 4:134 (as *L. Brysiana*); 11:402. G.C. III. 42:248. G.M. 50:627. Gn. 60, p. 196. C.O. 7.—A showy, tall-growing species. Var. **Nyléptha**, O'Brien. Fls. large; sepals tinted with yellow and rose, lightly spotted with purple toward the tips; petals broader, more suffused with purple; lip bright purple in front, paler at the side lobes. G.C. III. 3:176. Var. **Túrneri**, Warner. Fls. large, richly colored; sepals and petals bright amethyst-purple, with deeper veins; lip with a large purple blotch on the middle lobe; side lobes white, tipped with rose. Gn. 47, p. 319; 49:384 and p. 385.—One of the finest of the genus. Var. **prasiàta**, Reichb. f. Sepals and petals rose, tinged with green; labellum white at the base and side lobes, middle lobe crimson-purple.—Var. *supérba* is advertised.

2. **amánda**, Rolfe (*L. amánda*, Reichb. f.). Natural hybrid between *C. intermedia* and perhaps *L. crispa*. Pseudobulbs thin, fusiform, 5–7 in. long, 1–2-lvd.: lvs. shorter than the pseudobulbs, cuneate-oblong, acute: fls. in pairs, from a small, narrow spathe; sepals oblong-ligulate, acute, light rose, with a grayish hue outside, wavy; petals similar but broader, with darker-tinted nerves on the inside; lateral lobes of the labellum enveloping the column, rich dark purple; middle lobe transversely oblong, short, emarginate, wavy, separated from the others by an exceedingly short isthmus, veined with rich purple. Brazil. I.H. 38:135.

3. **corbeillénsis**, Maron. Garden hybrid of *C. Loddigesii* and *L. pumila* var. *marginata*. Pseudobulbs 5–6 in. long, fusiform: lvs. about 6 in. long: fl.-stalk 2–3 in. long, bearing 1–2 showy fls. about 5 in. across; sepals and petals bright rose, the latter veined with deeper purple lines; throat of the labellum veined with yellow on a white ground; blade intense purple, bilobed and undulate. C.O. 5.

4. **Stelzneriàno-Hardyàna**, Maron. A garden hybrid of *Lc. elegans* var. *Stelzneriana* and *C. Hardyana*. Plants vigorous: pseudobulbs 7–8 in. long: lvs. 10 in. long by 2½ in. wide: sepals pale clear rose, deeper on the edges; petals undulate, rose on the margins, fading almost to white at the center; labellum purple-magenta, undulate lacerate on the margin, with a broad purple line in the center of the blade and 2 large white spots in the throat.

5. **callistoglóssa**, Rolfe (*L. callistoglóssa*, Reichb. f. *Lc. Arnoldiàna*, Hort.). Garden hybrid of *L. purpurata* and *C. labiata* var. *Warscewiczii*. Pseudobulbs as in *L. purpurata:* lvs. 12 in. long: petals broad, oblong, acute; sepals narrower, all pure rose; middle lobe of the labellum broad, retuse, dark purple, with yellow on the disk; side lobes small, obtuse-angled. C.O. 8. Gn.W. 10:501. G. 28:441.

6. **Dominiàna**, Rolfe (*L. Dominyàna*, Reichb. f.). Garden hybrid. Plants having the general habit of *C. Mossiæ:* pseudobulbs fusiform, rather short, 1-lvd.: lvs. linear-oblong: raceme bearing few large, hand-

some fls.; sepals narrowly oblong, acute, light purple, with dark reticulations; petals broadly cuneate-oblong, wavy, light purple; labellum cucullate, with the middle lobe large, spreading, all wavy and crisp, deep blackish purple. F.M. 1878:325.—Raised for Veitch by Mr. Dominy from a cross between *C. Dowiana* and some lælia,—according to Reichenbach, *L.* (*Lc.*) *elegans*. R. A. Rolfe suggests the more probable parentage of *C. Dowiana* and *L. lobata*. The first plant flowered in Aug., 1878.

7. **Andreàna,** Maron. A garden hybrid between *C. bicolor* and *Lc. elegans*. Pseudobulbs 8–12 in. long, st.-like: lvs. oblong, 6 in. long: fls. 6–7 in. across, rose-violet; sepals and petals spreading, narrowly oblong, with the margins recurved, those of the petals undulate; labellum contracted in the middle, with a subquadrate toothed and undulate middle lobe, violet-purple. R.H. 1896:328.

8. **Sallièri,** Maron. Garden hybrid between *L. purpurata* var. *Williamsii* and *C. Loddigesii*. Pseudobulbs 1–2-lvd., about 10 in. high: lvs. 8 in. long, 3 in. wide: fls. several on a stalk, which is shorter than the lvs., 5–6 in. across; sepals and petals mauve, with deeper lines; labellum tubular, colored like the segms., and expanding into a carmine blade, pale at the tip.

9. **radiàta,** Maron. Garden hybrid of *L. purpurata* and *C. nobilior*. Pseudobulbs almost round, bearing 1–2 coriaceous lvs. 7 in. long by 2½ in. wide: fl.-stalks about 7–8 in. long, bearing several large, showy, violet-red fls.; labellum deep red, with purple veins and a whitish throat.

10. **Duvaliàna,** Hort. Hybrid between *L. purpurata* and *C. Luddemaniana*. Sepals and petals half-spreading, light mauve; labellum broad, dark maroon-crimson on the lobes and in the throat, which is traversed by darker lines.—According to Arnold & Co., handsome fl. of striking appearance.

11. **exímia invérsa,** Hort. Hybrid between *L. purpurata* and *C. Warneri*, the inverse cross of *Lc. eximia*. Sepals and petals deep rose-purple; labellum bright magenta-crimson.—Said by Arnold & Co. to be one of the finest hybrids yet raised between these genera, resembling *C. Warneri*.

12. **Martinétii,** Maron. Garden hybrid between *C. Mossiæ* and *L. grandis* var. *tenebrosa*. Fls. resembling those of the *C. labiata* group; sepals and petals rose-violet; labellum red to mauve, pale at the margins, and netted with numerous deep red veins. G.M. 46:511.

13. **Schilleriàna,** Rolfe (*L. Schilleriàna*, Reichb. f.). Lvs. 8 in. long: fl.-sts. 20 in. long; sepals and petals white, elongate-lanceolate; labellum veined with purple on the throat; disk purplish yellow, middle lobe spotted crimson-purple. A natural hybrid between *C. intermedia* and *Lc. elegans*. Brazil. Var. **álba,** Hort. Petals and sepals pure white; middle lobe of the labellum rich carmine-magenta, presenting an agreeable contrast. June, July. I.H. 31:526. Gn. 17:132.

14. **velùtino-élegans,** O'Brien. Garden hybrid of *C. velutina* and *Lc. elegans*. Resembles in habit a stout form of *C. velutina:* fls. fragrant, 3–4 on an upright st.; sepals and petals creamy white, tinged with nankeen-yellow and veined with rose; labellum bluish white at base, side lobes folded over the column; middle lobe broad, toothed and crisp on the margin, rich crimson-purple, veined with white and having an orange blotch at the base.

15. **intermèdio-flàva,** Maron. Garden hybrid of *C. intermedia* and *L. flava*. Of medium habit: sepals and petals clear yellow; labellum with a bright rose-purple blotch in front.

16. **Dormaniàna,** Rolfe (*L. Dormaniàna*, Reichb. f.). Natural hybrid of *C. bicolor* and *L. pumila*. Pseudobulbs terete, thin, slender, about 1 ft. long, 1–2-lvd.; lvs. oblong-ligulate, acute: peduncle 2–5-fld.; petals and sepals narrow oblong-ligulate, olive-brown, marbled outside with wine-red spots; labellum light purplish white, with darker veins; middle lobe transversely obcordate, mauve-purple. Brazil.

17. **exoniénsis,** Rolfe (*C. exoniénsis*, Reichb. f.). Garden hybrid probably between *C. labiata* and *L. crispa*. Sepals ligulate-acuminate; petals oblong-cuneate, plicate, all tinted light blue; labellum undulate, crisp, deep orange at base with whitish side lobes; middle lobe rich purple, with darker veins.

Lc. Aclándiæ=L. purpurata × C. Aclandiæ.—*Lc. Adólphus supérba*=L. cinnabarina × C. Aclandiæ. Fls. waxy; sepals and petals reddish Indian-yellow, ruby-spotted; front of lip and tips of lateral lobes purplish rose. G.C. III. 32:111. G.M. 45:666.—*Lc. Álbertii*=L. purpurata × C. velutina.—*Lc. Heinrich Hasselbring.
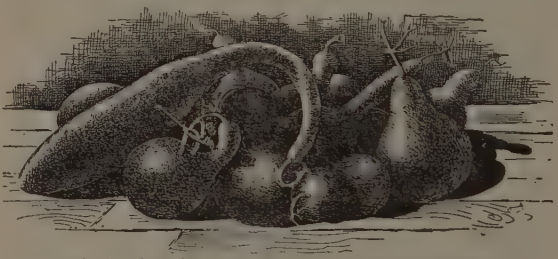
George V. Nash.†

LAGENÀRIA (Latin, *lagena*, a bottle). *Cucurbitàceæ.* Gourd. Calabash Gourd (the true calabash is Crescentia). Probably one species, although several specific names have been given to the various forms: a tender tendril-vine, producing hard-shelled fruits in very many forms that are used for ornament and in the making of utensils; and the rampant vine makes a good temporary screen or cover.

Plant musk-scented, with a sticky feeling, monœcious or diœcious: fls. solitary, white, funnelform, very soft in texture, withering in the sun; staminate fls. on very long, slender stalks (usually exceeding the lf.); pistillate fls. mostly short-stalked, with three 2-lobed stigmas and hairy ovary: tendrils forked, long and slender: st. striate-grooved, soft-hairy: lvs. large, soft-pubescent, cordate-ovate or reniform-ovate, sometimes angled, the edges obscurely apiculate-sinuate, on prominent or long petioles. **L. leucántha,** Rusby (*Cucúrbita Lagenària,* Linn. *C. leucántha.* Duch. *L. vulgàris,* Ser.), is widely grown in tropical countries and is often spontaneous; probably native in Trop. Afr. and Asia. To this species belong the gourds known in this country as Hercules' club, sugar-trough, dipper, snake, calabash, bottle, miniature bottle, depressa, and others; see *Gourd*, Vol. III. In some countries, the young fr. is said to be eaten as we eat summer squash.



2059. Various forms of gourds, Lagenaria leucantha.

Lagenaria is a tender annual, which should receive the culture of squashes. The season in the northern states and Ont. is often too short for the full maturity of the frs., particularly if seeds have been brought from the S. Give a quick warm soil and sunny exposure. In the N., seeds may be started inside in pots, or on inverted sods, after the manner of cucumbers. The lagenarias are rampant growers, often running 30–40 ft., and covering the ground or a fence with a dense mass of large, roundish, soft lvs. It is exceedingly variable in its fr., and has received many species-names as *L. microcárpa*, R.H. 1855:61; *L. claváta; L. pyrothèca*, R.B. 23, p. 198; *L. virginàlis*, white-fruited, G.C. III. 11:85; var. *longíssima*, Gt. 48, p. 159; *L. verrucòsa*, Hort., with ball-shaped very warty fr., Gt. 39 (1890), p. 106. *L. verrucòsa* var. *Giordaniàna*, Hort., is a form with warty pear-shaped fr. The hard shells of the frs. are used for drinking-cups, water-jugs, and many domestic utensils. From the pear-shaped shell of a small-fruited form the Paraguayans drink their famous *maté*, or Ilex tea. Some of the commonest forms are shown in Fig. 2059. The long curved forms are often called snake gourds in this country (not to be confounded with snake cucumber, which is a Cucumis). These are sometimes several feet long. The form with a constricted middle is the bottle gourd. The grooved musical instrument in Spanish Amer. known as guira, guichara or caracho, is made from the gourds (marimbo) of this plant. The South African calabash pipes are derived from this plant and not from Crescentia.

L. H. B.

2060. Crape myrtle.—Lagerstrœmia indica. (×¼)

LAGENÓPHORA (*flask-bearing*, referring to the shape of the involucre). *Compósitæ*. Small perennial scapose herbs, resembling Bellis, allied to Brachycome, sometimes planted. Scapes sometimes bearing lvs., slender, unbranched; heads solitary and small, with a short involucre having bracts in about 2 rows; receptacle convex and naked; rays in 1–3 rows, usually white, female and fertile; disk-florets perfect: fr. compressed, more or less beaked, the pappus wanting.—Species about 16, mostly in Austral. and New Zeal., but some in E. Asia and in extra-tropical S. Amer. They are probably adapted to outdoor cult. in parts of the S. *L. Fórsteri*, DC., the "native daisy" of New Zeal., is described by Cheeseman as a small daisy-like herb, either tufted or with creeping and rooting stolons furnished with tufts of radical lvs. at the nodes: lvs. radical or cauline, the blade orbicular to obovate and 1 in. or less long, coarsely dentate or nearly lobed: scape 1–6 in. long, sometimes with 1–3 minute linear bracts; head ¼–½in. diam., the rays white and revolute, numerous. Variable. G.C. III. 49:69. *L. Billardièri*, Cass., of India and Austral., has lvs. radical or nearly so, oblong or obovate, sinuate-toothed: scape slender, 3–4 in., from a rootstock with thick fibers: head ⅙in. diam., with white short rays: variable in size of head.

L. H. B.

LAGERSTRŒ̀MIA (Magnus v. Lagerstrœm, 1696–1759, a Swede and friend of Linnæus). *Lythràceæ*. Showy-flowered shrubs and trees, one of which (the crape myrtle) is much planted in the southern states.

Leaves opposite or the uppermost alternate, mostly ovate, entire: fls. in axillary and terminal panicles, with bracted peduncles and pedicels, pink, purple or white; calyx with a funnel-shaped tube and 6–9 lobes; petals mostly 6, crinkled or fringed, with a long, slender claw (Fig. 2061); stamens many to very many, long, some of them upward-curved; ovary 3–6-celled, with a long bent style and capitate stigma: fr. a caps.; seeds winged at the top.—Species, according to Koehne (Engler's Pflanzenreich, hft. 17, 1903), 30 in S. and E. Asia, Austral., Philippines, New Guinea. The crape myrtle, *Lagerstrœmia indica*, is to the S. what the lilac and snowball are to the N.—an inhabitant of nearly every home yard. It is a strong-growing shrub, reaching a height of 10–35 ft., deciduous-lvd., producing an abundance of soft fringed and showy fls. in summer. The normal form has pink fls., but varieties with blush, white and purple fls. are not uncommon. It is hardy as far north as Baltimore, but north of that latitude it needs protection; even with protection it cannot be grown north of the Long Island region. *I. speciosa* is very little grown. Neither species seems to thrive in S. Calif. The many other promising species of Lagerstrœmia appear not to have been intro. commercially in this country.

índica, Linn. (*L. chinénsis*, Lam.). Crape Myrtle. Figs. 2060, 2061. Glabrous, smooth- and brown-barked shrub, with rather small (2 in. long) elliptic or oblong sessile mostly acute lvs.: panicle open, sometimes minutely pubescent; fls. usually bright pink, but there are blush, purplish and white forms; calyx not ribbed, glabrous or nearly so. Widely cult. in India, but probably native to China. B.M. 405. R.H. 1857, p. 627; 1874:130. Gt. 6:128; 54, p. 230. G.W. 6, p. 13; 10, p. 109; 13, p. 145. Gng. 1:151; 5:281. A.F. 9:85. F.E. 31:643.—Grown everywhere in the S. Atlantic and Gulf States for its profuse summer bloom, and sometimes it has escaped. The crape myrtle is of the easiest cult. The old bushes bloom profusely, but the plant will produce fls. the first year from seed. The seeds start readily in spring if sown in boxes in autumn and are not allowed to dry out. It is also prop. readily by cuttings of ripe wood. The bloom may be increased by cutting back so that fresh growth is secured. The plant may be grown in a tub or pot in a cool greenhouse, and will bloom 2 or 3 times a year if it is cut back. It has no special soil requirements. In the N. the root may survive if it is well protected, and strong shoots will arise that give bloom the same year. Sometimes the plants are lifted in autumn, carried over winter in a cellar and planted out in spring. As the crape myrtle blooms almost continuously for a period of 2 or 3 months (beginning in June far S.), it well repays what care may be given it under glass or in regions where it is not fully hardy.

speciòsa, Pers. (*Munchaùsia speciòsa*, Linn. *L. Flos-Regìnæ*, Retz. *L. Regìnæ*, Roxbg.). Tree, 50–60 ft., with elliptic or long-lanceolate obtuse lvs. 4–8 in. long: panicle large; fls. 2–3 in. across, varying from rose to purple from morning to evening, the calyx grooved, the petals erose-wavy: caps, 1 in. or more long. India. G.C. III. 15:77.—A noble plant in Trop. India; also intro. in S. Calif. In the Old World sometimes grown under glass and on walls out-of-doors.

L. H. B.

LAGÉTTA (native name in Jamaica). *Thymelæàceæ*. Lace-Bark. Three W. Indian trees, one of which, *L. linteària*, Lam., is familiar in Jamaica as yielding the beautiful and delicate lace-like material derived from many layers of the inner bark; this material has the look of a gauzy fabric, and it is used in the making of many articles of ornament and use. Sometimes the tree is grown under glass in collections of economic plants. It grows 20–30 ft. high:

2061. One flower of Lagerstrœmia indica. (Natural size) glabrous: lvs. alternate, broad-ovate, pointed, 3–5 in. long, evergreen: fls. small, white, in terminal racemes or open lax bractless spikes; calyx tubular-cylindrical, 4-toothed; corolla 0; stamens 8; ovary ovoid, with a single style and broad stigma: fr. small, globose, inclosed in the persistent base of the calyx-tube. B.M. 4502. J.F. 1:19. The lace-bark of New Zeal. is a very different plant, *Hoheria populnea* and also *Gaya Lyallii* (Malvaceæ). L. H. B.

LAGUNÀRIA (named for its resemblance to Lagunæa, which is now considered a section of Hibiscus and commemorates a Spanish botanist, Andrés de Laguna, 1494 or 1499–1560, physician to Pope Julius III). *Malvàceæ.* An Australian (or Norfolk Island) tree cult. outdoors in S. Calif. and indoors in Eu. It has large pale rose fls. like Hibiscus, 2½ in. across, with 5 spreading lobes, a column of stamens and a 5-lobed shield-shaped stigma. It differs from Hibiscus in having only 3, 4 or 5 deciduous bractlets, while Hibiscus usually has 5 or more. Lvs. entire: fls. axillary; calyx 5-toothed; ovary 5-celled.—Species probably only 1.

Pátersonii, Don. Scurfy-pubescent on young parts and infl.: lvs. oblong or broad-lanceolate or sometimes ovate-oblong, 3–4 in. long, white beneath when young: pedicels very short: bractlets at base of fl. 3–5, very obtuse and united; calyx about ⅓in. long; petals narrow, 1½ in. or more long, somewhat tomentose outside.—The Norfolk Isl. form (B.M. 769, as *Lagunæa Patersonia*) is more scaly-tomentose, lvs. broader, and bracts earlier deciduous. They may be different species or botanical varieties. The tree cult. in Calif. attains a height of 50 ft., making a regular pyramidal head and having a fine display of fls.; said to be well adapted to street planting. L. H. B.

LAGÙRUS (Greek, *lagos*, a hare; *oura*, a tail). *Gramineæ.* HARE'S-TAIL GRASS. A hardy annual: spikelets 1-fld., aggregated in a close panicle forming an ovoid head; scarious glumes persistent and clothed with fine woolly hairs: lemma with a dorsal awn.—Contains a single species, native of the Medit. region, cult. for ornament, the small white heads being used for dry bouquets. Seeds may be sown in fall and plants set out in spring.

ovàtus, Linn. Fig. 2062. Culms tufted, about 1 ft. high: lvs. and sheaths downy. R.H. 1890, p. 488. V. 3:217, 247. Dept. Agric., Div. Agrost. 20:86.—An attractive grass with soft white woolly heads 1–2 in. long. A. S. HITCHCOCK.

2062. Lagurus ovatus. (×¼)

LALLEMÁNTIA (J. L. E. Avé Lallemant, botanist of St. Petersburg). *Labiàtæ.* Annual or biennial herbs, of ornamental value for the flower-garden.

From Dracocephalum the genus differs in the character of the upper lip, in which the lateral lobes are on the face of the middle lobe: glabrous or canescent: lvs. opposite, dentate, the upper ones passing into narrow sessile floral bracts: fls. small, blue; calyx tubular, 15-nerved, straight, 5-toothed; corolla-tube slender, included in calyx or somewhat exserted, the throat widening; corolla-limb 2-lipped; stamens 4, didynamous; style 2-lobed: nutlets ovoid.—Species 4, Asia. **L. canéscens,** Fisch. & Mey. (*Dracocéphalum canéscens,* Linn.), is annual or biennial, 18 in.: lvs. narrow, long-petioled, the floral lvs. sessile: fls. blue, in whorls, with oblong ciliate bracts; corolla-tube exceeding calyx. Asia Minor, Persia. Variable; one form (var. *álbida,* Voss) being white. July, Aug. L. H. B.

LAMÁRCKIA (J. B. Lamarck, 1744–1829, distinguished French naturalist, author of the Lamarckian philosophy of organic evolution). *Gramineæ.* An ornamental annual grass, often cult. under the name of *Chrysurus cynosuroides* and *C. aureus.* Spikelets of two kinds, the fertile 1-fld., long-awned, surrounded by the long sterile spikelets of many obtuse glumes, arranged in a 1-sided crowded panicle.—Contains a single species, native from Medit. region to Afghanistan, intro. in Calif. Seeds may be sown in the spring, or better in the fall, and plants set out in the spring. **L. aùrea,** Moench. (*Achyròdes aùrea,* Kuntze). GOLDEN-TOP. Fig. 2063. Culms 6–12 in. high. R.H. 1890, p. 546. Dept. Agric., Div. Agrost. 20:147.—A handsome grass with oblong feathery golden yellow rather dense panicles 2–3 in. long. A. S. HITCHCOCK.

2063. Lamarckia aurea. (×¼)

LÀMIUM (Greek for *throat,* referring to the shape of the corolla). *Labiàtæ.* DEAD NETTLE. Annual and perennial herbs of the Old World, of which several run wild in this country as weeds and others are cultivated as hardy border plants.

Botanically, Lamium is distinguished by a 2-lipped corolla, of which the tube is somewhat longer than the calyx, the upper lip ascending and concave, and the lower one 3-lobed: stamens 4, in 2 pairs, ascending under the upper lip: fls. in axillary or terminal whorls, often rather showy: lvs. opposite, mostly crenate-dentate and petiolate: calyx awl-toothed.—Low herbs, of some 40 species in Eu., N. Afr. and Asia.

Lamiums are diffuse mostly pubescent or hairy herbs, commonly decumbent at the base and often almost trailing. They are of the easiest culture in any open soil. Useful for rockwork. The cultivated kinds are perennial, and are commonly propagated by division.

maculàtum, Linn. (*L. álbum* and *L. purpùreum,* Hort., not Linn. *L. variegàtum,* Hort.). Straggling or half-trailing perennial, the tips ascending, slightly hairy: lvs. long-petioled (except the uppermost), cordate-ovate, blunt, round-toothed: fls. 1 in. long, ascending in the clusters, the upper lip strongly arched or hooded, the tube 2–3 times longer than the calyx, hairy within. Eu. —Fls. usually purple-red, but sometimes varying to white (when it is known as *L. album,* but the *L. album* of botanists is a different plant, having pointed and sharp-toothed lvs.). The lvs. are usually whitish blotched along the midrib (var. *variegàtum*), and in this form it is common about old gardens, trailing in the waste places. The plant is also run wild. *L. purpureum* of the botanists is annual (see suppl. list below).

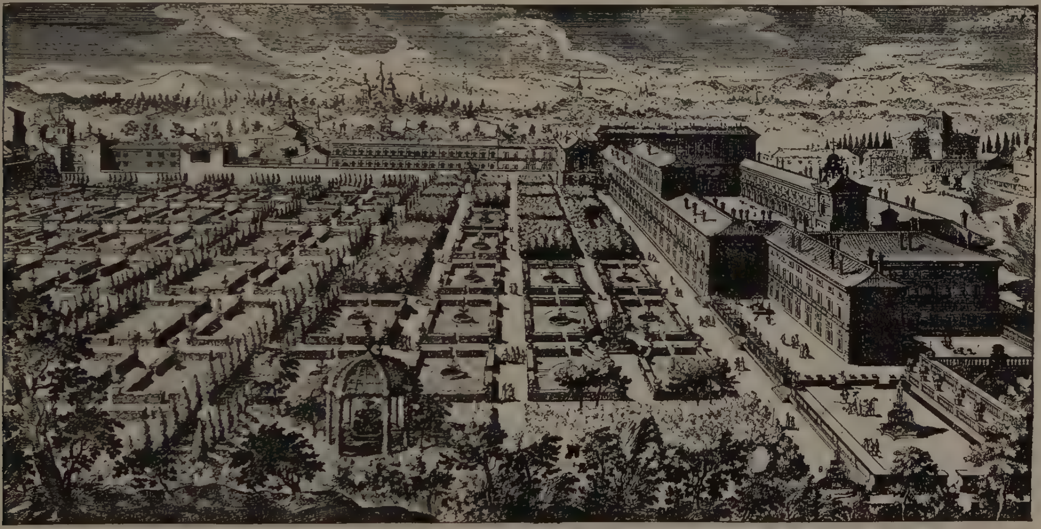
eriocéphalum, Benth. St. much branched, glabrous: lower lvs. long-stalked, puberulent, small, orbicular, somewhat incise-crenate; floral lvs. larger, deeply toothed, sessile or nearly so: calyx villous; corolla 3–4 times longer than the calyx, straight, purple. Taurus.—Said by some to be annual.

Galeóbdolon, Crantz (*Galeóbdolon lùteum*, Huds.). YELLOW ARCHANGEL. Perennial, to 1½ ft. high: lvs. ovate, petioled, toothed, only slightly or not at all cordate: fls. yellow, in dense axillary whorls; calyx-teeth short; corolla-tube scarcely exceeding calyx; upper lip long, arched. Woods and shady places, Eu. and W. Asia.—Little cult. in this country.

L. álbum, Linn., not Hort. Perennial with white fls. in close axillary whorls: lvs. petiolate, coarsely crenate, sometimes with a white spot in center. Eu., Asia.—*L. purálbum* is a garden hybrid between L. purpureum and L. album.—*L. purpùreum*, Linn. Annual with purplish red fls. in leafy whorls: lvs. small, orbicular, long-petioled, the upper ones short-petioled and ovate: there is a form (L. incisum, Willd.) with cut lvs. Eu., Asia. L. H. B.

LAMPROCÓCCUS: *Æchmea.*

LANDÓLPHIA (Landolphe, commander of a W. African expedition). *Apocynàceæ.* About 60 species of hairy or glabrous shrubs, mostly climbing by specialized tendrils, of Trop. and S. E. Afr. and adjacent islands, probably not regularly cult. Lvs. opposite, varying in size; stipules wanting: fls. mostly white or yellowish, small to medium-sized, rarely as much as 2 in. long in bud, in corymbs or panicles; sepals 5, free or connate at base; corolla salverform with a short more or less cylindrical tube, the lobes 5; stamens included; ovary entire, 1-celled; stigma conical, 2-lobed: fr. a globose or pyriform body, sometimes large. Some of the species are sometimes mentioned in horticultural literature but do not seem to be listed by dealers in ornamental plants. Most of them are presumably warmhouse subjects. Some of them are rubber plants. See Cyclo. Amer. Agric., Vol. II, p. 559. L. H. B.



2064. Gardens of the Pope, on the Quirinal, Rome. From Falda's "Li Giardini di Roma."

LANDSCAPE GARDENING is the application of garden forms, methods and materials to the improvement of the landscape; and the landscape, in this relationship, is any area, large or small, on which it is possible or desirable to develop a view or a design.

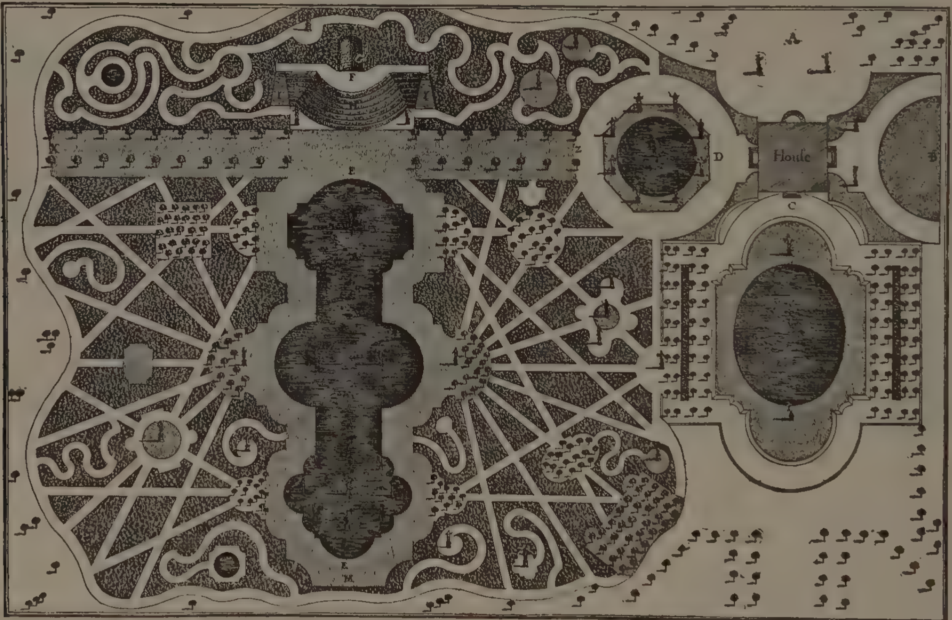
The art that designs and makes landscapes is known mostly by the name landscape architecture, although there is now a tendency to call it by other names. Landscape gardening is the older term; but this term is considered not to be broad enough or bold enough to suggest the large elements of design that form an underlying part of the art. The art of the constructing landscape artist is more than gardening. In this Cyclopedia, which deals with horticulture, there is naturally no attempt to cover the subject of landscape architecture; only the gardening or horticultural phases and their implications are considered, and this is why the term landscape gardening is used. This will also explain why many of the important landscape subjects are omitted from this discussion, as city planning, civic improvement, and the like (see *Garden Cities*, page 1313): for these phases are not particularly horticultural.

Here are brought together several discussions on the use of plant materials in the plan of the home ground and in the making of public landscapes. The articles are as follows:

The art of designing landscapes (Manning), page 1783.
The Japanese garden (Tanimura, Verbeck), page 1789.
Formal gardens (Vitale), page 1793.
The landscape treatment of small grounds (Cowell), page 1796.
The landscape treatment of parks (Olmsted), page 1801.
Landscape cemeteries (Simonds), page 1807.
Horticultural phases of civic art (Waugh), page 1811.
Landscape extension (Miller), page 1813.
Lawns and lawn-making in landscape planting (Parsons, Berckmans), page 1816.

"Gardening may be divided into three species—kitchen-gardening—parterre-gardening—and landskip, or picturesque-gardening: which latter is the subject intended in the following pages—It consists in pleasing the imagination by scenes of grandeur, beauty, or variety. Convenience merely has no share here; any farther than as it pleases the imagination." These are the opening lines of "Unconnected Thoughts on Gardening," by the poet William Shenstone, 1764. These sentences probably gave the world the term landscape gardening, to embody the growing desire to make grounds like nature. Milton, Addison, Pope, and the Dutch painters, expressed the awakening to the charms of the external world and hastened the day of freedom and naturalness. These and others had protested, directly or indirectly, against the artificialisms of living, as Bacon, also, in the following sentence, had protested: "As for the making of Knots or Figures, with divers Colored Earths, they be but toys, you may see as good sights many times in Tarts. . . I do not like Images cut out of Juniper, or other garden-stuff; they are for Children."

One does not know what Shenstone's protest meant until one knows the style of gardening that had been and still was in vogue. Gardens were fantastic constructions, elaborate with designs and formalities, cramped with geometrical details. A Roman garden (Fig. 2064) was good in its place, but there are other conditions and other ideals. Only infrequently can such gardens as these find the proper setting. If effective, they must be dominated or supported by architecture. In the freer atmosphere of the open country, they are evidently artificial: they are conceits. The reader will catch the feeling of the formal gardens of a later time by looking at Fig. 2065, which is a reduction from one of Batty Langley's designs in his "New Principles of Gardening," 1728. Langley seems to have been the extremest of geometricians. In fact, Part I of his book on gardening treats "Of Geometry." Yet his plates suited the taste of the time. The particular plan which is shown in Fig. 2065 he describes as follows: "The House opens to the North upon the Park A, to the East upon the Court B, to the South upon the Parterre of Grass and Water C; and Lastly to the West upon the circular Bason D, from which leads a pleasant Avenue ZX. The Mount F, is raised with the Earth that came out of the Canal EE, and its slope H, is planted with Hedges of different Ever-Greens, that rising behind one another of different Colours, have a very good Effect, being view'd from M, I, I, are contracted Walks leading up the Mount." The ideas of the time are further reflected in Fig. 2066, which is a reproduction, on a smaller scale, of one of Langley's pictures of artificial ruins. It is one of his "views of the Ruins of Buildings, after the old Roman manner, to terminate such Walks that end in disagreeable Objects; which Ruins may either be painted upon Canvas, or actually built in that manner with Brick, and cover'd with Plaistering in Imitation of Stone."



2065. One of Langley's "Designs for gardens that lye irregularly to the Grand House." 1728.

The awakening love of nature and of the spontaneous life, as expressed in writings and paintings, soon found expression also in gardens. In verse, Pope gave rules for the laying out of a spontaneous garden. The accompanying plan of Shenstone's garden, the Leasowes (Fig. 2067), and the picture of a glimpse therein (Fig. 2068), show how far his conceptions were removed from those of Langley, howsoever much they may fall short of the ideals of the present day. A full description has been left us of the Leasowes. Here is a glimpse: "Passing through a small gate at the bottom of the fine swelling lawn that surrounds the house, you enter upon a winding path, with a piece of water on your right. The path and water, over-shadowed with trees that grow upon the slopes of this narrow dingle, render the scene at once cool, gloomy, solemn, and sequestered; and forms so striking a contraste to the lively scene you have just left, that you seem all on a sudden landed in a subterraneous kind of region. Winding forward down the valley, you pass beside a small root-house, where on a tablet are these lines:

> 'Here in cool grot, and mossy cell,
> We rural fays and faeries dwell;
> Tho' rarely seen by mortal eye,
> When the pale moon, ascending high,
> Darts thro yon limes her quivering beams,
> We frisk it near these crystal streams.' "

The garden-art of the old time was largely a corollary of architecture. The garden-art of the present time, particularly amongst English-speaking peoples, exists for its own sake. Yet, one cannot say that the old-time garden-art is unlovely, or that it contradicts the canons of good taste. The two belong to different categories of esthetic feeling, and the mere fact that both of them use plant-subjects does not make them comparable. Garden-art, like painting or music or literature, develops along racial or national lines. The Latins and their descendants have liked the formal and conventional gardens; and since these gardens express the personal and national emotions, they need no apology, notwithstanding the fact they are condemned by some landscape gardeners.

A different type of endeavor is that which attempts to interpret nature in the making of landscapes. The ideal landscape garden, like the ideal landscape painting, expresses or emphasizes some single thought or feeling. Its expression may be gay, bold, retired, quiet, florid; but if it is natural, the expression will conform to the place and the purpose, and the expressions are not matters of rule. It should be a picture, not a collection of interesting objects. Mere planting and grading do not make a landscape garden: in fact, they often spoil it.

It is not enough to plant: the plants must be in the right place. A yard or a lawn with bushes or flower-beds scattered over it may be interesting as a mere garden, but it is not a landscape garden. A real landscape garden has open breadth, space, atmosphere. It usually has an open center with mass-planted sides, and vistas to the offscape. Incidentally, it may be ornamented; yet many persons even confound ornamental gardening with landscape gardening: it would be as proper to confound house-painting with architecture.

It will be gleaned from the above that the term landscape gardening precisely expresses the art of making a garden or tame area which shall be a landscape or picture. It is not every place that is adapted to the making of a landscape picture. Formal gardens are often more to be desired than natural gardens. They may conform to the principles of art, but it is the art of formal gardens, not of natural gardens. Too often have formal gardens been judged from the viewpoint of the natural or landscape garden, and hence confusion has arisen. There is now a slow but wholesome reaction against the too exclusive use of the true landscape or "natural" garden. In practice, however, one cannot separate the two, so that one practitioner is, or should be, competent to undertake either or both, although it naturally develops that a practitioner may have special aptitudes and qualifications in one or the other.

Landscape gardening has undergone many fluctuations of taste within a century. Such changes are to be expected as long as the human race makes progress. The constantly increasing wealth in plants modifies the spirit of the work. It is no longer worth while to follow any school or cult. Every style has its use and place. In small places, a formal or formalesque treatment of the ground plan may be desirable. In larger and freer places, the spirit of the fields may be given fuller expression. The fundamental consideration is that there must be a general theory or plan before any grading and planting takes place or structures erected, —these latter parts are only means to an end. Yet many persons who would be called landscape gardeners conceive that to plant a place is the whole of the problem. The working out of the details of the plan is to landscape gardening what building is to architecture, or what pen-work and grammar are to literature. It is the industrial or constructional part of the work. It is what has been called landscape horticulture (Bailey, "Garden and Forest," 1:58). It has to do with all the details of kinds of plants, the care of them, the making of lawns, and similar problems. The American writings on landscape gardening are mostly writings on landscape horticulture and kinds of plants.

A marked development of landscape art in recent time is the application of it to very small and plain home grounds and to secondary civic areas. Even the back yard of the tenement is within its range (Fig. 2075). This is an illustration of the extension of social democracy.

The practitioners.

The first American practicing landscape gardener of note was apparently André Parmentier, who came to this country from Belgium about 1824 and established a nursery on ground which is now in the heart of Brooklyn. He was a man of great taste and skill, and Andrew J. Downing considered his "labors and example, as having effected, directly, far more for landscape gardening in America than those of any other individual whatever." He laid out many places, even as far away as the southern states on the south and Montreal on the north. The first American book on landscape gardening was from the pen of A. J. Downing in 1841, without having undergone the tedious evolution of preliminary and imperfect editions which characterize so many horticultural and kindred writings. It was immediately popular, and exerted a great influence on American horticulture. Downing was also the second prominent practicing landscape gardener, although his untimely death left the country with no completed works of his genius. His best known public pieces are the grounds of the Smithsonian Institution and Lafayette Square, Washington, but it is doubtful whether the subsequent treatment carries out the spirit of the designer. A. J. Downing's pomological work was continued by his painstaking brother Charles; but the artistic work dropped at his death, and Henry Winthrop Sargent, who edited the sixth edition of the "Landscape Gardening," in 1859, declared that "there has been no one since Mr. Downing's death who has exactly filled the niche he occupied in the public estimation." Ignatz A. Pilat, an Austrian by birth, was early chief landscape gardener of Central Park, and a general practitioner of influence following Downing.

2066. An improvised ruin. 1728.

The subsequent genius of American landscape gardening, and the one who carried the art to its highest points of excellence, is Frederick Law Olmsted, who as a young man was inspired by Downing, and who became a landscape gardener when he was placed in charge of the improvements of Central Park, New York City, about 1856. For more than thirty years, Mr. Olmsted gave his talents wholly to this delightful art, and, more than any other American, moulded and crystallized public taste respecting the appreciation of landscape gardening. A leading spirit in the construction of this great park was Calvert Vaux, who, with Olmsted, was joint author of the original plan. Vaux was also associated with Downing. The initiation of Central Park as a pleasure-ground inaugurated the modern park systems of the country, and created what the Earl of Meath has designated the "veritable rage for park making" which has "seized the American public."

Within recent years, the number of practitioners of landscape gardening has greatly increased. The art is established in popular estimation. It has now fairly won its place, also, with the architects and artists. Tastes may change, but the changes will affect only the minor applications of the art. The desire for artistic treatment of grounds is ineradicable. Two national societies are conservators of the landscape gardening and rural art of the country: American Society of Landscape Architects, American Association of Park Superintendents. Other societies are also related to landscape art, as the American Civic Association, American Scenic and Historic Preservation Society, and the horticultural bodies. The subject is also taught in colleges in its amateur aspects and in a few places professionally. The discussion of city-planning has now taken hold of the public imagination, although little has yet been done to visualize the necessity of country-planning.

The kinds of landscape gardens.

The improved landscape, we have said, may be large or small. It may also represent any condition of residence or of public use. The illustrations herewith indicate, better than words, some of the merits and some of the possibilities in landscape. (Many of the illustrations have appeared in "Garden and Forest.") The improved or designed landscape area should appropriate the good views and scenes beyond itself or adjacent to it. The distant view in Fig. 2069 should not be missed from any landscape garden if one is so fortunate as to be in the region of such an offscape. Even familiar objects, as a spire, a distant residence, a well-proportioned bridge (Fig. 2070), a noble tree, may add much interest if brought into the home landscape by means of vistas. It would be a special good fortune if the landscape garden could lead into any kind of a wood or forest, particularly into anything so distinctive as the Jersey pines shown in Fig. 2071. In many places, the grounds may lead off naturally into an informal country road (Fig. 2072), which is always interesting with its irregular lines, variety of life, and stimulating suggestions. A stream is always an entertaining boundary, particularly when a walk may follow it, as in Fig. 2073.

America excels in landscape art applied to the rural and garden cemetery. The first distinct movement toward a rural cemetery was made in 1825 by Jacob Bigelow, of Boston, whose work was soon taken up by the Massachusetts Horticultural Society. As a result of the agitation by this admirable organization, Mt. Auburn Cemetery, at Cambridge, was established and incorporated in 1831. The consummation of this enterprise gave to the world a cemetery distinct from churchyards, removed from the city, and softened by the gracious touch of nature; and thereby, also, the young Massachusetts Horticultural Society set an example to all similar organizations and achieved for itself enduring fame. The work of Repton and Loudon had not then enlivened and broadened the conceptions of landscape gardening, and Mt. Auburn, whilst an excellent work of its kind, is not a landscape-garden cemetery. The modern art of garden-cemetery making—in which, as in the park, the continuous expanse of greensward is the fundamental conception of the fabric—originated with Adolph Strauch, who, in 1854, became superintendent of Spring Grove Cemetery, Cincinnati. Strauch's work at Spring Grove Cemetery has justly given him lasting fame, and his book describing the place must be consulted by anyone who traces the evolution of the garden-cemetery. The Board of Directors of the cemetery said, at the time of his death, that "he had filled the measure of his ambition by the consent of his profession, which ranked him as the equal of Repton and Pückler-Muskau as a master of art in landscape creation, which had been finally proved by him to be possible to be successfully applied in adorning and making attractive the last resting-places of humanity." At present, about one hundred or more burial-places in various parts of North America can be said to be landscape-garden cemeteries.

The successful practice of landscape gardening depends, first, on an artistic temperament and an inherent love of nature; second, on an intimate knowledge of plants; and third, on familiarity with various arts and handicrafts, as the making of roads, grading, draining, enriching the land, and the like. Landscape gardening must be sharply distinguished from gardening: the former is the making of pictures with plants; the latter is the growing of plants without reference to the picture. In one, the interest centers in art: in the other it centers in plants. Since landscape gardening is primarily a matter of taste, it is impossible that it be dominated by arbitrary rules. However, a few general precepts and suggestions may be useful.

The motive of a true landscape garden, as already explained, is to make a picture. The picture should have a landscape or nature-like effect. The place should be one thing: it should emphasize some thought or feeling. It should have one central or emphatic object, and avoid scattered effects. In general, the advice is to bunch or mass the planting. One must distinguish sharply between the fundamentals and the incidentals,—those conceptions that are to give the character or tone to the place, and those that are embellishments or ornaments. In usual practice it is essential to keep one or more spaces open, and to plant the sides or boundaries with masses. The use of single or individual plants is only to emphasize or to heighten an effect, not to give it character: they are incidentals. Ornament should be an incident. Foliage and verdure is a fundamental requisite. In natural sod regions, greensward is the canvas on which the picture is spread. Plants are more

LXII. Example of the large rural park.—View in Prospect Park, Brooklyn.

useful for the positions they occupy than for their kinds. Walks and drives are no part of a landscape picture: they are a necessity, but they may be made to conform to the spirit of the picture, and also to add human interest to it. The place for walks and drives is where they are needed: otherwise they have no use or purpose. It is the part of a good landscape gardener to make his grounds conform to the buildings: it should equally be the part of an architect to make his buildings conform to the landscape. There should be views to desirable objects in the outlying landscape or the offscape. The undesirable parts or views should be covered. The designer should aim for a good prospect from every window in a residence, including the kitchen. The trees and bushes are sheared only when hedges, curiosities, and formal gardens are wanted: they assume their natural forms when a landscape garden is wanted (Fig. 2074). No tree or plant is placed until one is sure that it will mean something and add to the total good effect.

The open center is possible even in very small areas. Fig. 2075, for example, shows the principle applied to an ordinary city back yard. The planting is massed against the fences, and a free space is secured for other purposes. In a larger way, the open center is admirably illustrated in Fig. 2076. Again it is shown in a parking plan, Fig. 2077.

It is not to be assumed, however, that the principle of the open center is to apply invariably, or that it is always to face the direction of the public view. The planting may be disposed specially for the purpose of screening from the highway, and it may have artistic merit of its own. Fig. 2078 shows a good screen-planting, and it is well adapted to the character of the residence. Yet even in such cases as this, the open center may be an essential feature of the design, but it may face inward, and constitute an interior open space, rather than outward. Rather close and intimate planting may accentuate the character of a very personal or special residence, and a very open feature may detract from the interest. In such a case as that shown in Fig, 2079, for example, a rather heavy planting about most of the building would probably heighten the interest. This is a construction that suggests seclusion. Even with the open center, however, the bases and angles of buildings may be well tied to the lawn-surface by planting.

In city openings and certain other places, the open center may be no part of the plan. Here the only purpose may be to provide shade, shelter, and seating-space. In some cases, only a promenade is desired. The landscape, in the artistic sense, comprises these areas as well as those in which it is possible to secure a pictorial presentation with some completeness or wholeness of effect. Every open space, in city, village or open country, may find improvement under the hand of the landscape artist. Even the wharving or dock area of seaports, which are perhaps the least likely places for landscape work, may afford space and opportunity for artistic treatment; Fig. 2080, being a design by W. Hamilton Bell, is a suggestion of this kind.

Historic and important places.

Many estates and country-seats have contributed to the development and establishing of taste in landscapes in this country, particularly in the eastern states. It requires age to bring out the essential qualities of an estate. When a person builds a house of some pretension and plants the grounds on a design, he is anxious at once to photograph the effort; the result is that our periodicals are full of pictures of immature and undeveloped places.

There is need of a careful and sympathetic study of the historic estates in North America, as a contribution to the development of taste in both architecture and landscape treatment. The study should include the estates of the far Southwest and the Pacific coast, that represent the Spanish influence. At this place, only a few of the notable estates in the eastern part of the country may be mentioned. They naturally represent the English influence and the background of greensward.

In many respects, Mt. Vernon stands first. It remains a wonderful example of the satisfactory use of a landscape. Hyde Park, the Vanderbilt place on the Hudson, is one of the estates notable for its landscape features; also the Morton place at Rhinecliff, on the Hudson; Wodenethe, the H. W. Sargent place at Fishkill; Holm Lea, the estate of Charles S. Sargent at Brookline, Massachusetts; the Twombly place, in New Jersey; the Hunnewell estate at Wellesley, Massachusetts: Irving's country-seat, Sunnyside, on the Hudson; Jefferson's home, Monticello, Charlottesville, Virginia; the Drayton estate near Charleston, famous for its azaleas; the Middleton place on the Ashley, near Charleston, where early plantations of camellia were made; old estates on the James River, as Westover and Brandon; the great Vanderbilt place at Biltmore, North Carolina. There are many others. Mention might also be made of the Bartram estate in what is now Philadelphia, for while it was never a landscape garden, it has contributed much to the stimulation of interest in trees; and its historic value is great. See the biographical note on Bartram, Vol. III, p. 1564; also the references in Vol. I, p. 348.

2069. A worthy offscape.—Lake Yumoto, Japan. Page 1780

Some of the above places are prized chiefly for their horticultural features, in relation to landscape, rather than for the fundamental design. The Hunnewell estate is remarkable in this feature. The places laid out under the inspiration of A. J. Downing were notable for their planting, although there are few of these estates now remaining. It is probable that Downing's influence persists in some of the older places even if unrecognized by present owners and visitors. Downing admired the rural gothic in domestic architecture, and the change in taste in this direction has undoubtedly had something to do with the loss of interest in his landscape work. His untimely death prevented him from making a great impression in the way of actual examples. Downing had a real love of plants, and his knowledge of trees was remarkable and unusual among Americans of his time. His regard for trees was notable, and he knew their possibilities in the reconstructed or planted landscape. His ideas and his tastes were communicated to his friend and neighbor, Henry Winthrop Sargent, who transmitted them to another generation, and some of the most interesting and beautiful country places made in America in the last sixty years owe their existence to Downing's influence. It was this influence which has made the Arnold Arboretum what it is, a natural garden of great beauty and not a mere collection of trees and shrubs. It must be remembered, also, that when Downing died the only public grounds in the United States which could in any sense be called a park was Boston Common, and that it was through his knowledge and influence that Central Park in New York was established in 1852; and it was Central Park that led to the establishment of public parks and playgrounds in every American city.

2070. A commanding object in the offscape.

The artistic values in some of the old places, and the reasons for them, are discussed by Warren H. Manning, in the remainder of this introductory article.

"The principal lesson to be learned from a study of historic private estates in America is the fact that our system of land tenure does not lead, as does the English method of entailment, to the holding by a family of such estates for centuries. While there are many houses and some large property holdings in the older parts of this country that have remained in one family for many generations, even back to the period of the original grant or purchase, they are usually not notably fine estates. There are very few, if any, of such estates upon which the first acreage or the original design and intent of the founder have been continued in all essential details for three or four generations.

"Mount Vernon, under the ownership of an association, has been maintained much as it was designed by General Washington, although the original acreage of the property has been much curtailed since Washington's day, and the planting is now being restored. Such associations as the Virginia and Massachusetts societies for the preservation of antiquities, and the several colonial societies have rescued, restored and are maintaining many old homes with but a fragment of the original estate attached. Some cities are maintaining historic homesteads as public museums or in public parks, as New York holds the Van Cortlandt homestead in Van Cortlandt Park, which includes parts of the old estate diverted to other than its original uses.

"Family associations have been formed to hold the ancestral homes with a small part of the original farm holdings, such as the Fairbanks, Wyman, and Manning associations in Massachusetts. The United States Government holds Arlington, the home of Robert E. Lee, with most of the land diverted to other than the original use. The Pendleton house in Providence, Rhode Island, and the Swett house in Portland, Maine, are held as typical furnished homes of their day in association with art museums through the bequest of the last owners.

"This brief review indicates that it is the historical antecedence, not the beauty of landscape and gardens, that is responsible for the preservation of most of the ancient homes and estates, notwithstanding that the beauty of landscape determined the location and first design of many of the early homes and the grounds about them.

"There are two broad distinctions to be made between the notable properties of the North and of the South. In the South, the great estates included acres by the thousands with the extensive cultivation of great fields, while in the North the acres seldom ran into the hundreds, and the cultivation was usually more intensive. In the South, there was a comparatively small proportion of the property set aside about the mansion for lawns, gardens and other ornamental purposes, as compared with the homes of the North. In the South, the home buildings were usually broadly spread out, with symmetrical wings on each side of a main central structure. In this central structure, the use of the tall columns of the classic order, with either a projecting or a recessed portico or porch, was almost universal. However, there was a marked individuality in most of the buildings and a fairly well-marked distinction between two types of design that have been referred to as the Georgia-Colonial and the Virginia-Colonial, the distinction of the latter style being due chiefly to the work of Thomas Jefferson which was typified by his own home, Monticello, and by his University of Virginia.

"In the North, the mansions were usually carried a story or more higher than in the South. They were more compact and restrained, for pilasters were used very largely in the place of columns. Instead of the balance of wings on either side of the main structure, the wing was usually added at one side or at the rear, and extended to include the various outbuildings and shops with stables forming the terminus of the group, or being rather closely associated with the house in a group near at hand; whereas in the South the workers' houses, the plantation barn, and the shop for the wheelwright, blacksmith, the cotton press, and sheds for the drying of tobacco, were in separate groups at some distance from the mansion.

"Before the Revolutionary period, and for a quarter of a century afterward, the English influences in the design of estates, both North and South, were very marked. Within this period Thomas Jefferson's influence, not only in the design of buildings but also in the design of grounds, was powerful in the South, and especially in Virginia. At the end of this period André Parmentier exerted an important influence in the North, especially about New York.

2071. A good background for a landscape garden. Page 1780.

"In this colonial period and subsequent to it, there was an exchange of native and exotic plant material, through such men as John Bartram, Peter Collinson, Benjamin Franklin, Thomas Jefferson, and others, supplemented by such agencies as the Prince's Nurseries at Flushing, Long Island, and the Winship Nurseries at Boston. This interest was reflected in the writings of A. J. Downing, the first notable writer and practitioner in the designing of landscapes, whose successor, Frederick Law Olmsted, initiated systems of parks that preceded the city-plan movement of today. This period of testing exotic plants and fruit trees in private grounds and in a few public parks, that extended through the middle and latter part of the last century, established the fact that many of these varieties were too short-lived to be of permanent value. Others thus secured not only an established place in our gardens by reason of their adaptability to our conditions and their evidence of long life, but also a permanent place in our flora by becoming naturalized in fields and woods of both the North and South. This experience in exotics was followed by an interest in the natives of both the East and West of the United States, which has led to their use in nurseries and in gardens. In recent years, new groups of exotic plants and more of our native plants, are coming into general cultivation through the interest of Professor Sargent and the Arnold Arboretum, where a careful test is made before the plant is recommended for general use, and through the Department of Agriculture at Washington, and the Experimental Farms of Canada. Through these various agencies, an important part of whose support has always come from the owners of large private estates, a very large share of the earth's surface has been searched for new varieties.

"There are, therefore, represented in the great private estates one group in which special attention was given to the growing of collections and fine specimens, such as Wodenethe, the Sargent estate on the Hudson; Glen Cove, the estate of the late Charles A. Dana at Glen Cove, Long Island; the Payson estate in Belmont, Mass.; and the Hunnewell estate at Wellesley, Mass. In another group, the beauty of landscape was the dominant motive in design and maintenance, as represented by the Montgomery place south of Clermont on the Hudson, which was regarded by Downing as being second to none in America, and by Charles Eliot was placed among the first in his series of articles on "Some Old American Country-seats" in "Garden and Forest." In this same class would be the A. T. Lyman and Christopher Gore estates in Waltham, Mass. (Fig. 2076); Sunnyside, the Washington Irving place on the Hudson; Monticello, Jefferson's homestead at Charlottesville, Virginia; and the Arlington estate, the home of Lee near Washington.

"The work on the large private estates of the future should and probably will be on broader and more definitely directed lines than was represented by the great estates of the past. While there will always be individuals who prefer to make collections of interesting specimens, such owners will be able hereafter to avoid duplication of effort and work with clearly designated groups of plants, or secure more tangible return through plant-selection and plant-breeding by coöperating with such agencies as the Arnold Arboretum, the departments at Washington and Ottawa, and state institutions, instead of attempting to record and establish great general collections.

"There will be a group of individuals whose chief interest will center in the development of landscapes in a very much broader way than has been the general practice of the past, and which is indicated by the development of town park systems and town plans, and will be enlarged to include a national plan that will fit the lay of the land.

"The express train, automobile, and the aëroplane to follow, are training the eyes to see real landscapes more and the details of landscapes less. This breadth of view will lead men to become connoisseurs of the living landscapes instead of the painted landscapes alone. It will lead men to seek out the choicest landscape views and purchase them, and to acquire or control in these outlooks the essential features instead of attempting to acquire all the land for themselves."

Literature.

The best results in the planning of any place are to be expected when one employs a competent landscape gardener. Avoid the man who places great stress on flower-beds and unrelated designs. Yet one can do much by himself, and be the happier for the effort. Books will help. Some of the current American books on gardening as related to landscape are the following: Downing, "Landscape Gardening;" Kemp, "How to Lay Out a Garden;" Parsons, "Landscape Gardening," and "How to Plan the Home Grounds;" Long, "Ornamental Gardening for Americans;" Waugh, "Landscape Gardening" and "The Landscape Beautiful;" Maynard, "Landscape Gardening as Applied to Home Decoration;" Davis, "Ornamental Shrubs;" Van Rensselaer, "Art Out-of-Doors;" Bailey, "Manual of Gardening;" Underwood, "The Garden and Its Accessories." See *Borders, Banks, Garden, Herbs, Shrubs,* and other articles. The home vegetable-garden and flower-garden are discussed in Vol. III, p. 1738, p. 1747. L. H. B.

The art of designing landscapes.

Landscape gardening is one of the terms used to designate the profession that conserves, develops and creates landscape, locates and arranges artificial structures, plantations, and passages therein for the convenience and pleasure of man. It is practised professionally as a fine art by men and women who have also adopted such titles as landscape architect and landscape designer; and by some architects. It is practised as a part of their duties by some superintendents of public and private grounds and made a part of their business by some dealers in plants.

This landscape art may include all objects within the scope of vision, from a narrow strip of sky and foliage between buildings, a lawn, a garden, a town, to a horizon-sweeping panorama.

In this, as in all professions, many are mere copyists who, in all their problems, duplicate or adapt with minor variations, styles, plans and patterns originated by others to meet the special requirements and conditions of each of their problems.

The artists of the profession as well as artists among painters of landscape are striving to give a quality of distinction to each of their productions. This distinction comes from a study of the distinctive beauty of the locality in which they work; a beauty that may be partly or wholly hidden by extraneous material. The designer of the living landscapes must also acquire a knowledge of the conditions and requirements of the use to which all or parts of their landscape is to be put by its occupants. The landscape painter is free to choose his subject while the landscape-maker often must create a new beauty in wholly artificial landscape compositions. Artistic distinction of design is gained through the omission by the painter or removal by the landscape-maker of extraneous material and incongruous incidents and by additions that will give greater harmony and unity.

The principles of design in this art of landscape-making are very similar to those of the landscape painters who can produce on canvas phases of natural beauty with such skill as to give great pleasure to the eye, and sometimes a stimulus to the imagination that is the gift of genius alone. Every student and lover of the living landscapes should study the pictures of the Barbizon School and of such artists as Hobbema, Claude Lorraine, Turner, Fragonard, Corot, Constable, Inness, Church, and Wyant. Church and other painters have chosen for their subjects passages in the wholly artificial landscapes of New York Central Park that was designed and constructed by the senior Frederick Law Olmsted, who was the great master of the artists who design living landscapes.

While there is as yet no accepted distinction between the landscape works of those who practise under the different titles referred to, the names suggest a distinction that may be helpful in outlining various phases of professional work.

Landscape architecture.

Landscape architecture, the French term for the profession, could be properly applied to the designs that formalize landscape in a large way, as did Le Notre's at Versailles, or to big formal gardens of today filled with architectural structures or architectural and sculptural bric-a-brac wherein foliage and flowers serve only to relieve the rigidity and severity of such immobile forms.

2073. A boundary stream and walk. Page 1780.

The term landscape architect was first applied by the New York City Central Park Commission on February 20, 1862, to their advisers, Frederick Law Olmsted and Calvert Vaux, and was retained by Mr. Olmsted in his later practice and adopted by a majority of his successors, notwithstanding the fact that the dominant spirit of American work is essentially informal. By informal in landscape gardening is meant naturalistic design in which irregular massing of the landscape elements predominates. By formal is meant design depending on a more exact symmetry.

There is a spectacular impressiveness in big formalized landscapes and gardens that is sure to elicit the brief admiration of the multitude. There may also be a beauty in proportion, a justness in scale, and a refinement of detail that will satisfy the discriminating critic, and give pleasure even to those whose greatest satisfaction comes from the greater variety and intricacy of informal and natural beauty. There are situations in which the formal treatment is undoubtedly best.

In formal design the land is forced to fit the plan; in informal design the plan is made to fit the land.

When there is abundant means properly to construct and maintain large formal layouts, they may with propriety be introduced in public parks and private show estates, especially in direct association with great buildings and their formal entrances and courts.

At the other extreme of formal design are the old-fashioned gardens with box-edged walks symmetrically arranged in a pattern that gives convenient access to beds.

Another distinctly informal garden type, the Japanese garden, is referred to here because it is so artificial in design and in construction. These gardens are conventionalized miniature landscapes. They may include miniature mountains with ancient, wind-swept, stunted trees, cliffs, ledges, turf, and water, or the imitation of water made in sand, edged or crossed by suitably placed stones. Very distinctly do these gardens appeal to the imagination. There is also a special sentimental significance given to the form and arrangement of such garden features as lanterns, seats, groups of stones and plants, similar to the significance of flower-stem and fruit arrangements in Japanese homes made to convey expressions of sentiment, courtesy and compliment to guests and friends. While we cannot reproduce a genuine Japanese garden with our materials, we may make our gardens appeal more to the imagination in expressing certain types of our own landscapes, and more to sentiment in establishing a recognized significance for the incidental structures therein.

A garden, formal or informal, in which especially favorable conditions are established for the growth of fine garden flowers, should have a place in grounds where the surpassing interest is not given by some natural feature. It is desirable that such gardens be entered so directly from a home as to become outdoor compartments of it.

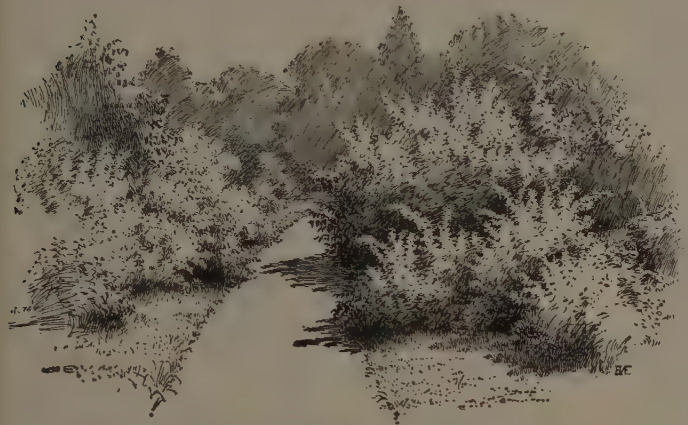
The design of small house grounds, small shut-in estates, and public grounds will fluctuate in style from period to period between the bondage of the rigidly formal to the freedom of informality. Nature's modeling of the surface in broad landscapes can never be greatly modified except by the introduction of artificial bodies of water, and by the arrangement of masses of foliage, of fields and of habitations as seen from selected viewpoints.

Landscape design.

Landscape design, a term as yet adopted by few practitioners, could properly be applied to the development of the broad landscapes and passages of natural beauty. Such beauty can be modified and enhanced but can rarely be reproduced by man or his money within a short time limit, as can be the lawn and the garden.

In the selection, development and refinement of broad landscape beauty, there would be little of the formality that has been mentioned as especially appropriate to the term landscape architecture, little of the new construction and exotic planting to be referred to later under landscape gardening.

Broad landscapes vary greatly in impressiveness and beauty from different viewpoints, even within a limited area, and the first problem of officials representing public ownership, or a private owner, before arranging with engineer or architect for detailed structural plans, is to choose with his landscape adviser the finest of the various available and accessible viewpoints. This would involve a study of the far distance, the middle distance, the foreground and the nearby foliage frame, of each of the sites that can be arranged conveniently to meet the needs of the public or the owner. In such study it may be often developed that the property purchases should include distant single trees, groups of trees, or forests and fields that may be quite separate from the main property and be held because they are essential elements in the beauty of the outlook.



2074. Good plant forms for the free style of design. Page 1781.

Another landscape of distinction would be a woodland glade walled in by splendid old trees, each one a patriarch with a ripened beauty and dignity that age only can give, the forest floor covered with an exquisite carpet of such evergreen trailing plants as linnea, wintergreen, bearberry, ferns and mosses, all having a refinement of detail that comes only with years of natural selection and adaptation to such special conditions.

In the development of such a forest retreat, foliage- and branch-framed pictures would be opened up into the woods or to fields or distant sky-lines beyond by carefully studied tree and branch removals. The beauty of adjacent woodland detail, such as a shrub or herb group in which one variety predominates, would be enhanced by the removal of other plants that interfere with a foliage and stem, floral or fruit composition already having or promising to have marked distinction. In other places the varieties elsewhere removed would predominate and be the ones retained and fostered.

Such notable broad landscapes or woodland passages will be seen by the owners and observers from the buildings or grounds of a resort or from a home about which would be the gardens and fields of utility and beauty that are needed to sustain and give pleasure to many persons.

The time will also come when persons of advanced taste will have their collection of living landscapes with simple retreats from which they and their friends can enjoy each scene. The automobile now makes it feasible to have such possessions in widely separated locations, and the cost of acquiring and maintaining such living pictures need be no greater than is often devoted to painted pictures.

Already nation and cities are beginning to preserve and acquire fine scenery in public reservations, and choice holdings of individuals will be devised to cities or to the nation as paintings and sculptures now are.

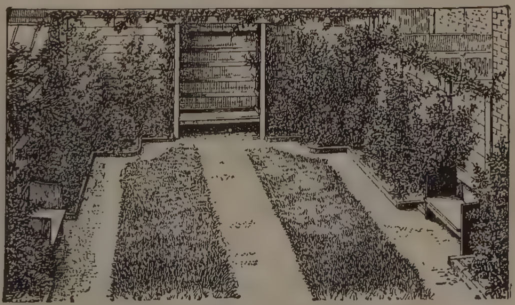
This work of the landscape designer wherein it is deemed more important to preserve and develop natural beauty than to destroy it and substitute artificial beauty, applies as well to the little home ground upon which natural beauty exists as to great estates or to great landscapes.

Landscape gardening.

Landscape gardening or gardening, the English term for the profession, now and in the period when such classics as Wheatley's "Observations on Modern Gardening," Price's "On the Picturesque" and the works of Repton and Gilpin were produced, is a term that may properly be applied to such distinctly horticultural phases of the profession as may be treated in detail in an horticultural cyclopedia. The term may well have special application to landscapes that must be largely or wholly artificial, in which the planting is chiefly the product of horticultural establishments. Such landscapes are represented by the average small park and the intimate home outlooks of lawns and gardens, rather than by the wild woods, the fields and the wide views.

If the landscape be only a single window outlook in a city block against bare walls with just one opening in which appears a graceful tree or vine branch, silhouetted against the sky, the artist will so arrange plants and vines about his window-frame as to shut out the bare walls and make the sky and the branch the central attraction of his picture. Here may be gained as much pleasure from hourly changes in the sky background, seasonal changes in the foliage, and from the occasional bird or butterfly visitor, as many a rich man gains from his galleries of paintings and acres of gardens. For suitable selection of vines in shade or in sun to execute the artist's ideals for the frame about a window-opening and for the flowering plants to be used in association with the vines, one would look to the local florists' establishments.

The main subdivisions of the average house-lot are usually lawns, garden, laundry and service-yard and house and service entrance walks, or if the lot is large enough, these walks may be roads. (Fig. 2081.) The lawn and the garden should by preference be on the sunny side and directly associated with and entered from the home living side of the house. The service or utility entrance passages and compartments are usually placed on the shady side. It was once regarded as essential that the living-room be on the street side of the lot and the service-rooms at the back of the lot, regardless of exposures or outlook. It is now regarded as the best practice to give the living-rooms the most attractive exposures and outlooks regardless of the street, and to place service-rooms and yards next to the street, or at the side of the lot when this arrange-



2075. The open center in a small rear lot. Pages 1779, 1781.

ment gives the advantage to either living-grounds or -rooms. Such service compartments may be screened from the public gaze by lattices covered with vines or shrub plantations. Examples of such exceptional but sensible layouts are shown in Fig. 2082.

From lots surrounded by houses and back yards are likely to be one or more outlooks that are similar to and can be treated like the narrow window outlook referred to above. When views are to be seen from several positions in house and grounds and at various heights, the arrangement of the boundary foliage-frame as well as the planting about the house, gardens and yards becomes more complicated. Such planting will include small trees, shrubs, vines and herbs chosen because the heights, breadths and outlines at maturity will occupy the designated position without unfairly encroaching upon lawns, gardens, passages or light openings of buildings. When one considers that such large trees as maples, elms, beech, and ash spread at maturity 40 to 80 feet, it is obvious that they should not be used freely on small lots or parks. Often a single tree shuts out all the view, and to secure outlooks without cutting it down, it becomes necessary to make framed-in openings at different heights by the careful removal of branches and twigs.

In parks or estates measured by acres instead of square feet, the control of outlook, the arrangement, for inter-communication, concourses, recreation, garden and landscape compartments, are made with similar purposes in view and with similar material as is the case in the design and construction of smaller private grounds.

In the large open areas, elevations and distances are usually on the scale that permits the use of large tree borders in place of shrubs and small tree borders, as well as the creation of larger landscape units by so disguising boundaries and buildings beyond as to give a visual ownership to a great landscape. This was done in a notable way by Olmsted from the Overlook and from Hagbourne Hill in Franklin Park, Boston.

The plant materials.

In choosing and arranging planting for all this work in landscape, the adaptability of plants to soil and climate, the hardiness, freedom from disease and insect pests, would be considered before the brilliancy or peculiarity of flowers, foliage or fruit. Horticultural varieties and forms would usually be added to enrich the detail, not to make the masses of landscape plantations. Plantations are more effective and usually less expensive if few varieties are used in large quantities, rather than many varieties in small quantities.

Persons of refined taste prefer a landscape made up of plants having the normal green foliage, with all the exquisite variations in tone, texture and shade throughout the summer season that follow the spring's outburst of delicate pinks, grays, reds and yellows in the budding leaves. Such persons enjoy the modelling, the coloring, the bark patterns on trunks, the varied ramifications of branches and twigs in winter. They are entertained by the brief but gorgeous riot of autumn color as by a yearly Mardi Gras. For those who like to live with the garish, the spectacular and the peculiar, there are enough odd horticultural forms to make a lawn landscape of curiously distorted branches and of yellow, purple and variously blotched, dissected and twisted foliage.

2077. The free center.—The Meadow, Central Park. Page 1781.

A very few of the finest of such forms, like the sturdy purple and the weeping beech, the vigorous Schwedler's maple, the lace-like Japanese maples, are worthy of a place in a lawn planted with the finer exotics and garden varieties, especially if the plants that carry their conspicuous colors through the summer are not allowed to compete with fine distant views or quiet lawn landscapes. Such forms may well be placed in special compartments, in which each color is massed as one masses roses in a special rose-garden. The most serviceable of these garden forms are such fastigiate types as the Lombardy poplar, to make foliage screens in narrow spaces or to give such points of emphasis in green landscape as does the church-spire in the village.

There is an important place in plantations on large areas for such very rank and rapid-growing, easily propagated and therefore cheap trees as the cottonwood, willow, Russian mulberry, soft maple, catalpa, black locust, and in the warmer regions, the eucalyptus and the camphor tree. Such trees will give high, dense masses of foliage in different soils quickly. It is usual, however, to plant slower-growing, more permanent, sturdy and interesting trees, such as hard maples, oaks, magnolias, with these rapid-growing nurse trees, the latter to be gradually removed as the more permanent trees develop. In coniferous plantations, the rapid-growing and short-lived Scotch and Austrian pine and fir balsam are not infrequently used as a filler for the more permanent and valuable pines.

In working up detailed planting plans, the knowledge that some 5,000 species and named varieties of woody plants can be purchased in American nurseries, should lead to great conservatism in planting to avoid the mussy mass of odds and ends that are scattered all over the open spaces of some small home and park grounds even now, in spite of the good advice that is being conveyed to

2076. The free and open front.—Gore Place, Waltham, Mass. Page 1781.

the public in lectures, books, government and state publications.

The thorns, flowering dogwood, red-bud, wild crabs, and in the warmer sections the red bay, crape-myrtle and camellia, with a spread of 15 to 20 feet, are most suitable to give shade and make screens and borders in small lots. Such large shrubs as the weeping golden-bell, mock orange, syringa or Persian lilac have an ultimate spread of 10 to 15 feet, so they should not find place in a narrow part of the border. For small areas, such narrow, tall shrubs as the white lilac and panicled dogwood will be suitable to give high and medium high foliage. For medium high borders, such shrubs as Lemoine's syringa, Missouri currant, weigela, Van Houtte's spirea, faced with such small kinds as the dwarf deutzia, Indian currant, snowberry, Scotch rose and the dwarfer forms of the Thunberg's barberry are the safest to use.

When there is not too much lime in the soil, a broad-leaved evergreen bed can be established on the shady side of the house in which such tall varieties of rhododendrons, as *album elegans* or *album grandiflorum*, would be next to the blank house walls faced down with the lower-growing and more spreading crimson- or purple-flowered varieties, or with mountain laurel, edged with the low andromedas or dwarf rhododendrons.

The narrow strip next to a neighbor's blank wall or back yard, or between the entrance passages and the laundry or other service-yards, may be planted with such narrow tall-growing shrubs as the panicled dogwood, or such easily procured pyramidal trees as the Lombardy or Bolleana poplars, or the less common pyramidal varieties of the birch and ginkgo. If the space be very narrow, one could have a trellis covered with flat-growing vines such as the Boston ivy and the Japanese honeysuckle, which is nearly evergreen, or the Virginia creeper, which will also grow in shade. If a full evergreen cover is desired, the creeping *Evonymus radicans* is the safest vine for the North and the English ivy, or creeping fig (*Ficus pumila*), for the South, all of which will grow in shade. If broad spreading vines are permissible, then use such as the American or Japanese bittersweet, wistaria, trumpet-vine, grape and deciduous roses in the North and in the warmer section the evergreen Cherokee rose, the Macartney, Banksian and other climbing roses, the bignonias, and passion flowers.

One should determine to give the lawn plantation individuality, and distinction, but not eccentricity.

If it is desired that the gray-greens predominate, then the royal willow, the Russian olive, the sea buckthorn, the sage willow, or *Lonicera Alberti*, represent typical plants to use, ranging from middle-sized trees to very low facing-down shrubs. The mullein pink, *Alyssum saxatile*, and *Cerastium tomentosum* are herbs having a similar foliage color.

For a dark green lawn border in the North, the laurel-leaf willow, white fringe, Russian rose, bayberry and pachysandra would give a similar range of heights. In the warmer sections, such dark green plants would include the figs, laurels, guavas, and pittosporums.

If a yellow floral display in shrubs to extend well through the season is desired in the North, one could use the Japanese varnish tree, Scotch laburnum, Cornelian cherry, golden-bell, globe-flower, witch-hazel, Japanese barberry, and a little farther south the winter jasmine.

If a red floral display is desired in the warmest sections, the bottle-brush tree, crape-myrtle, Japanese quince, russelia, hibiscus and poinsettias are available.

There are also several families of plants such as the heath and rose families, or the Coniferæ, that contain a sufficient variety in size, outline, foliage, flower and fruit completely to plant a place.

2078. Protection-planting.—The home of Florence Nightingale, Lea Hurst, England. Page 1781.

These planting suggestions relate chiefly to the older parts of the country with normal conditions of soil, cultivation and humidity. There are many sections and localities in which special soil, climatic and cultural conditions dictate the use of different types of plants and also determine the extent and character of plans for the development of places. On the southern California coast and in the arid Great Basin between the coast range and the Rocky Mountains, turf and the ordinary cultivated plants must be irrigated, and, as water is expensive and limited in quantity, only small areas can be maintained in turf and gardens at the normal cost of eastern places. To have a green landscape during the dry bare-ground season in these sections, advantage may be taken of evergreen orange, lemon and olive orchards cultivated for their fruit crop that come into the views. For other evergreen trees, Monterey cypress, Monterey pine, eucalyptus, pepper and camphor tree, are most easily procured. For the unirrigated land there are evergreen native shrubs like the rhus, the manzanita, the madrona, the bay and ceanothus, but as yet they are not offered by nurseries in quantities at reasonable cost. In the place of turf, inexpensive quick ground-cover plants like *Lippia repens*, various mesembryanthemums, agaves and cacti are used.

In the South, also, owing to the difficulty of establishing turf, the large lawn areas of the North are impracticable. Here about the only grass that can be relied upon for permanent sod is the Bermuda grass, which is brown in winter. Many evergreen plants can be grown here, however, under ordinary cultivation that cannot be grown out-of-doors in the northern states, such as the ivy, camellia, gardenia, Indian azaleas, Chinese privet, photinia, magnolia, hollies and aucubas.

In such northern states as Minnesota and the Dakotas, with a snowfall so light as to allow the ground to freeze deep, evergreens do not succeed and many of the deciduous plants of eastern nurseries are unreliable.

Where the ground is so deeply covered with snow through the winter as to prevent deep freezing, as about the Great Lakes, more coniferous trees and evergreen shrubs can be grown, even rhododendrons and azaleas in protected localities, unless the soil be limestone.

In poor gravel and sand some plants, such as the bearberry, crowberry and hudsonia, that will not do well in good soil, will make an attractive and permanent ground-cover, but they are not offered in quantities by nurseries. Soils that are wet much of the year support a few plants such as buttonball, red maple and willow, arbor-vitæ and tamarack in the North; in the South white cedar, cypress and palmetto. On seashores exposed to constant winds and the spray of high tides, bayberry, huckleberry, and wild roses predominate in the North, and in salt-marshes, baccharis and iva. In the South the mangrove grows at the edge of salt-water.

The wet-land limitations may make distinctive and attractive landscapes, even though they are not so accessible, that are quite as worthy of preservation and development as the upland woods, fields and lawns.

2079. A type of house that needs much intimate planting. Page 1781.

There are limitations in the supply of material in nurseries that must be considered in making landscape planting plans. The plants most desired to carry out the designer's ideal may be too expensive or offered in too small quantities by the dealers. Therefore, a working knowledge must be had of the available material as well as a knowledge of the habits and cultural requirements of plants.

The grading and mechanical work.

In the development of areas for habitation and for the recreation of many persons, there must be underground pipes and surface grading. Roads and walks must be provided as well as means for supplying light and water, disposing of sewage and other wastes in a sanitary and sightly way. Grading is required about buildings and in the construction of roads, game-courts and gardens, and is often resorted to in order to secure such special effects as are indicated below: shutting out of sight a road or walk that crosses the turf foreground of a distant view or across a lawn view; making a building which stands below a road-level to appear nearer this level by having the surface slope away from the building into a valley with its opposite side at the road made more abrupt, and covered with low shrubs; making buildings on formal terraces appear nearer the ground-level by substituting for the terraces a gradual ogee or reverse curve.

There are usually two classes of roads and walks, the long indirect pleasure ways for occasional use that are preferably turf- or leaf-covered and the direct thoroughfares from house to town and from building to building that are in constant use and must be well drained and thoroughly constructed on easy grades.

A 5 per cent grade is regarded as the desirable maximum for horse-drawn vehicles. Curves, even sharp curves, are made through irregular steep land to gain the necessary length to give easy grades. With automobiles steeper grades are permissible, while less abrupt curves without obstruction to the view of the road are much more desirable. The tendency is to accept steeper walks with fewer steps than formerly, not alone in the cities where ramps are being substituted for steps in the great railroad stations, but also in country parks and private grounds.
